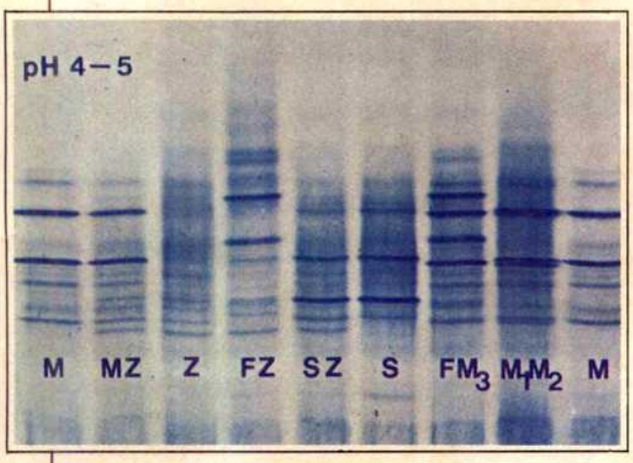
VERTICAL STRUCTURE OF SOUTH ATLANTIC CURRENTS



Only with the new LKB Horizontal E

Unequalled flexibility ir

READY-TO-USE GELS FOR MAXIMUM CONVENIENCE

All the owner of the LKB Horizontal Electrophoresis System needs to cover a wide range of electrofocusing applications is a supply of the popular and successful LKB Ampholine PAGplates. These allow the researcher to avoid the time and trouble involved in casting gels in the laboratory, while guaranteeing both high resolution and excellent reproducibility. As many as 96 samples can be separated simultaneously on a single PAGplate, enabling users with high workloads to spend their time screening samples instead of casting gels.

Eight phenotypes of α_1-antitrypsin are clearly identified using one of the convenient LKB Ampholine PAGplates ▼

ULTRATHIN GELS FOR MAXIMUM ECONOMY

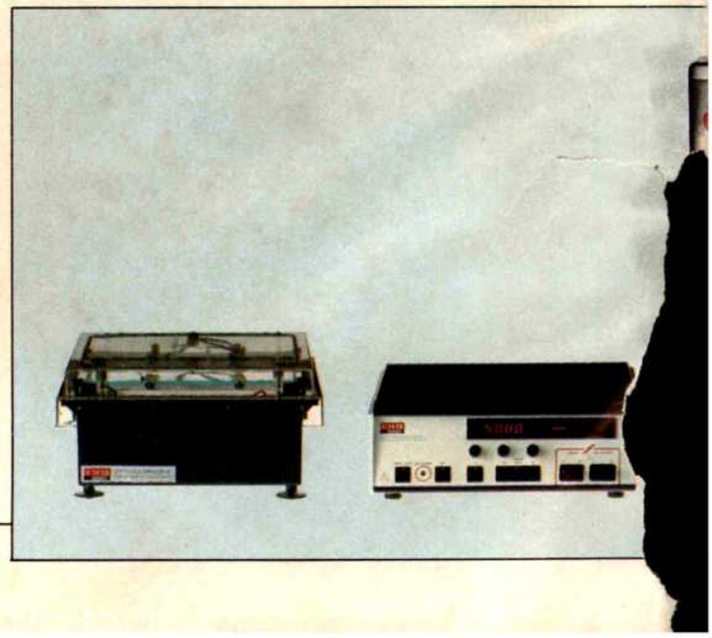
Anticipating the need for less expensive electrofocusing gels, LKB developed the new UltroMould: a simple device designed to cast bubble-free gels as thin as 0.1mm in less than 30 seconds. Based on a patented sliding plate method, UltroMould is easy to use, producing perfectly accurate and uniform gels and ensuring a high standard of reproducibility. Adding UltroMould to the LKB Horizontal Electrophoresis System means that significantly less gel solution and smaller sample volumes are required, resulting in far more economical electrofocusing.

LKB UltroMould casts bubble-free ultrathin gels in only 30 seconds, making gel casting quicker, easier and more certain ▶

THICK GELS FOR MAXIMUM CAPACITY

Original electrofocusing techniques used thicker gels, and even today you may still wish to work this way in order to achieve higher capacity. The LKB Horizontal Electrofocusing System lets you easily cast and run Ampholine gels up to 2 mm thick, allowing much greater sample volumes to be analyzed successfully. The 2 mm thick gels are also ideal if you are new to electrofocusing and are following a procedure described in the literature.

After the thick gel has been cast, the sample is introduced with the help of the sample application foil ▶



This is one in a series of advertisements describing the unrivalled versatility of the LKB Horizontal Electrophoresis System. For further information about analytical electrofocusing, and the many other applications of the system, send today for our brochure.

THE LKB SYSTEM

Only LKB can offer the research scientist a complete, integrated system in which each component works with and complements all the others. Based on the new and improved Multiphor II, the system also includes a 5KV power supply, thermostatic circulator, laser densitometer and data evaluation software.
In addition to the instrumentation, LKB provides a range of 18 major kits plus a complete programme of high quality chemicals, supplies and accessories, backed by the full worldwide support of the market leader in electrophoresis and electrofocusing.

LKB–the electrophoresis experts.

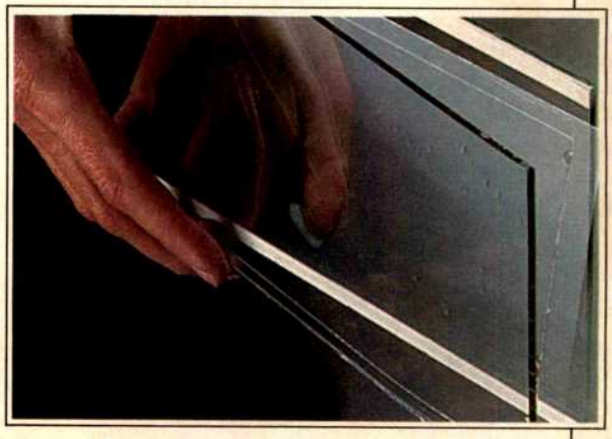
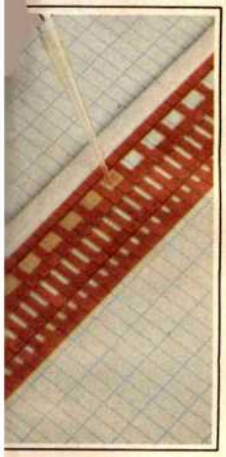
ctrophoresis System do you also get...



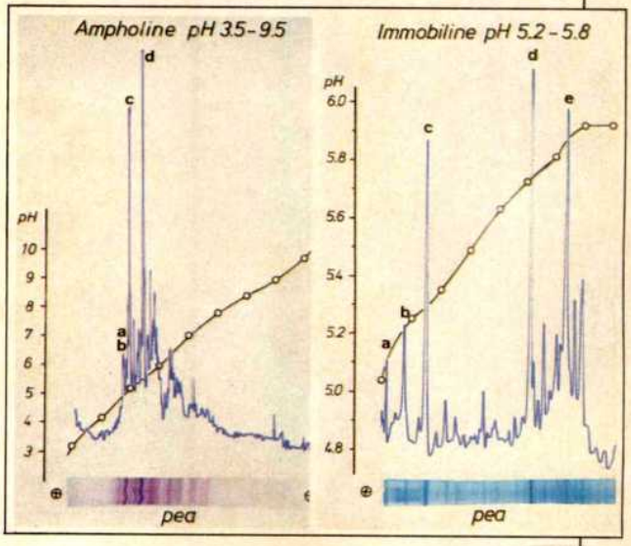
analytical electrofocusing

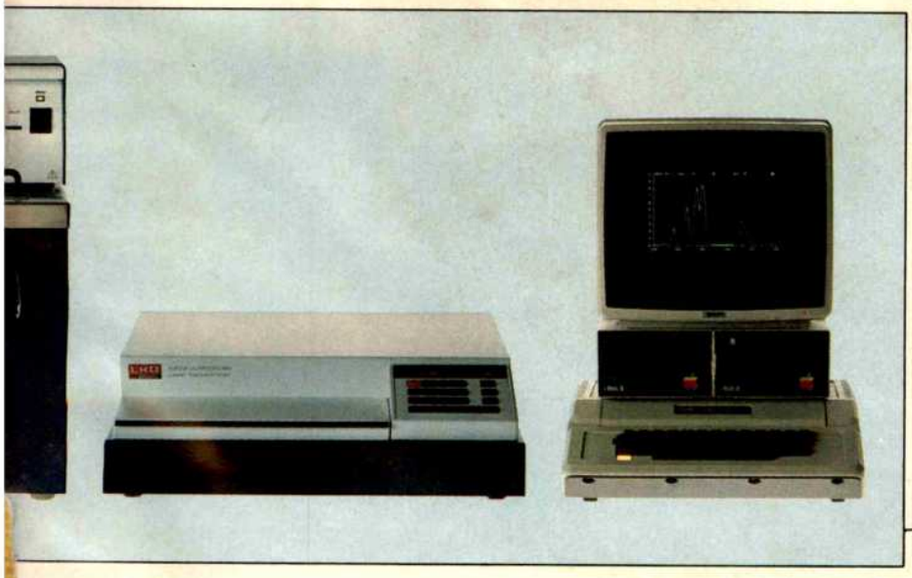


AGAROSE GELS FOR MAXIMUM POROSITY

Another of the many options available to the user of the LKB Horizontal Electrophoresis System is the application of Agarose electrofocusing gels. LKB supplies extremely pure agaroses, carefully developed for electrofocusing, and the original capillary casting method simplifies the task of producing 0.5 mm gels on GelBond Film backing sheets. Agarose is non-toxic and easy to handle and the entire analysis procedure, including casting and running, is very rapid.

Separating the GelBond Film from the glass plate gives a 0.5 mm agarose gel, firmly attached to its support and ready to use ▶





IMMOBILINE GELS FOR MAXIMUM RESOLUTION

The unique LKB Immobiline System is significantly different to traditional gels in that its pH gradient is an integral part of the gel. The system is designed to allow the user to select a pH gradient as wide as 3.0 pH units, or as narrow as 0.1 pH units, anywhere in the range 3.6 to 9.5. This tailoring of the gradient to suit specific applications permits extremely high resolution to be achieved with the LKB Horizontal Electrophoresis System. Stable and reproducible linear gradients having a slope as low as 0.01 pH units/cm are possible, allowing you to separate proteins whose pI values differ by as little as 0.001 pH units.

Comparison of traditional electrofocusing and LKB Immobiline System (courtesy of Dr A Görg et al, Technische Universität, München) ▶

^{125}I-labelled atrial peptides

Amersham's ^{125}I-labelled rat ANP (28-residue-sequence) in tissue autoradiography of guinea pig kidney and adrenal. Photographs kindly supplied by Dr P W Mantyh, Center for Ulcer Research and Education, UCLA, USA.

Labelled peptides

- (3-[^{125}I]*iodotyrosyl*^{28})**Rat atrial natriuretic peptide** (28-residue sequence) IM.186
- (3-[^{125}I]*iodotyrosyl*^{28})**Human α-atrial natriuretic peptide** IM.187

These ligands are supplied at a specific activity of ~2000Ci/mmol, ~74TBq/mmol.

Tracer and antiserum for RIA

- This reagent pack, IM.1871, contains a rabbit antiserum to human α-ANP which cross-reacts totally with the corresponding rat sequence and [^{125}I]human ANP. Sufficient for 250 assay tubes using the protocol provided.

Seen in all the best scientific circles

Pharmacia's new Molecular Biology Division has been formed by linking the established strengths of Pharmacia P-L Biochemicals with the separations expertise of Pharmacia Fine Chemicals, creating a group with an unequalled technology base.

This group is dedicated to providing molecular biologists with the tools and advice they need in their research.

Whether you are constructing your own plasmids, sequencing, or working with cDNA, we have the products and the fast delivery that you need.

Everything from nucleotides to separation products and enzymes to expression vectors, are available from one dependable supplier.

Look at our new catalogue and you will see just how much we have to offer.

Write or call us today for your free copy.

You'll be in good company.

Pharmacia... your partner in molecular biology.

- Galactic centre radio source

GUIDE TO AUTHORS

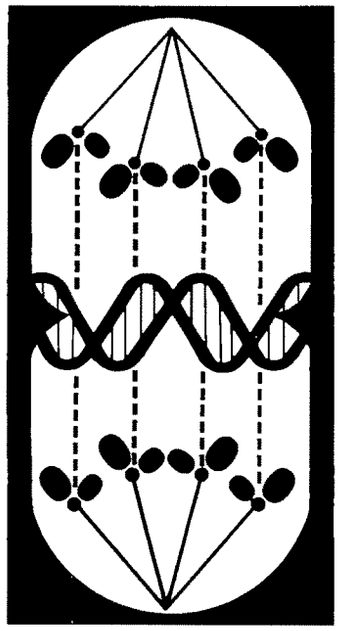
Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible:

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.



Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

nature

UPDATE IN MOLECULAR BIOLOGY 1985

Genes and Systems in Development

You are invited to join a select group of participants and some of the world's foremost speakers at NATURE's fifth international conference.

Presented in conjunction with the University of California at San Francisco.

OCTOBER 7, 8, 9, 1985—SHERATON-PALACE HOTEL SAN FRANCISCO, CALIFORNIA

The 1985 conference presented by NATURE, the international weekly journal of science, in association with the University of California at San Francisco will address what is perhaps the central unanswered question of biology today: How is the process of development directed by genes?

For three days, you will meet and listen to preeminent scientists, physicians and biotechnologists describe their research and first-hand involvement in experimental approaches involving the application of molecular biology to systems and organisms. Topics will include the diagnosis and therapy of genetic defects, homoeotic genes, yeast development, development of the immune system—including T-cell receptors—and the use of new biological materials in medicine and industry. Roundtable discussions will be held each afternoon to give delegates ample opportunity to mix with and question the speakers. Participants will have an opportunity to take part in detailed discussions and present their own ideas. Poster presentations are also being invited.

WHO SHOULD ATTEND

Senior Level Scientists, Medical Research Scientists, Biotechnologists, Scientific Policy Makers, R & D Scientists, Departmental Chairpeople.

TO REGISTER FOR THE CONFERENCE

Return the form with your check, credit card authorization, or an authorized purchase order.
Full 3-day registration fee: $375.00
Pay only $325.00 if you register before July 31.

LOCATION

The Sheraton-Palace Hotel located at 639 Market Street is convenient to the business and financial districts as well as downtown's most stylish shops and finest restaurants. Since its opening in 1875, this elegant hotel has hosted such world figures as seven U.S. presidents, Winston Churchill, Nikita Krushchev, Sarah Bernhardt, Enrico Caruso and Oscar Wilde.

RP433

ROOM RESERVATIONS

A large block of rooms has been set aside for attendees at preferred rates. However, we suggest you make your reservations early as delegate places and accommodations are filling fast. Rooms can be reserved directly with the Sheraton-Palace Hotel by calling 800-325-3535. Be sure to mention your participation in the NATURE 1985 Conference to qualify for special rates. Singles: $95. Doubles: $105 and $115.

CMEs WILL BE AWARDED

Extended Programs in Medical Education of the University of California School of Medicine in San Francisco designates this continuing medical education activity for 18 credit hours in Category 1 of the Physician's Recognition Award of the American Medical Association and the Certification Program of the California Medical Association.

BURSARY PROGRAM

Bursary program for selected graduate students to be announced during August 1985.

POSTER SESSIONS

To have your poster considered, please include a working title and brief synopsis of your topic and send to Posters Editor, Nature Publishing Company, 65 Bleecker Street, New York, New York 10012

YOUR REGISTRATION FEE COULD BE TAX DEDUCTIBLE

CONFERENCE DINNER
Our gala Conference dinner will be held Tuesday, October 8, in the historic, glass-domed Garden Court. To insure seating, please include your dinner ticket requirements and payment of $29.50 per person with your registration.

EXHIBITS
A major exhibition of scientific products and services will be held in conjunction with the Conference.

PROGRAM SCHEDULE*

DAY 1: MONDAY, OCTOBER 7

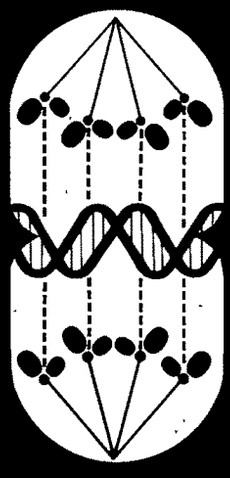
SYSTEMS

Speakers	*Topics*
F. Bloom (Research Institute of Scripps Clinic)	Vertebrate neural systems
J. Gerhart (U. of California at Berkeley)	Early development—Xenopus
C. Nüsslein-Volhard (Tübingen)	Early development—*Drosophila*
C. Goodman (Stanford)	Development of invertebrate neural systems
H.R. Horvitz (MIT)	Caenorhabditis

DAY 2: TUESDAY, OCTOBER 8

CELLS

Speakers	*Topics*
M. Davis (Stanford)	T-cell receptors
U. Storb (U. of Washington at Seattle)	B cells
J.M. Bishop (U. of California at San Francisco)	Oncogenes
M. Ptashne (Harvard)	Regulatory proteins
I. Herskowitz (U. of California at San Francisco)	Yeast development
E. Jaworski Monsanto	Plant transformation



DAY 3: WEDNESDAY, OCTOBER 9

GENES

Speakers	*Topics*
R. Palmiter (U. of Washington at Seattle)	Transgenic mice
D. Hogness (Stanford)	*Drosophila* homoeotic genes
W. McGinnis (Yale)	Mammalian homoeotic genes
T. Friedmann (U. of California at San Diego	Human therapy

*Additional speakers will also appear on the program.

SAVE $50 IF YOU REGISTER BEFORE JULY 31!

NAT

REGISTRATION FORM

To register for NATURE UPDATE IN MOLECULAR BIOLOGY 1985, mail this form with your payment to: NATURE PUBLISHING COMPANY, 65 Bleecker Street, New York, NY 10012

(Photocopy this form for additional applications.)

Please reserve _____ Conference registration(s) in the name of: (please type or print)

_____ and _____ seats

at the Tuesday Conference dinner in the name of: _____.

NAME **TITLE**

COMPANY/INSTITUTION

ADDRESS

CITY **STATE** **ZIP**

I understand that as a paid conference participant, I may attend all sessions and receive all programs and other materials.

My check for $ _____ is enclosed.

Charge my credit card as shown. ☐ **Amex** ☐ **Visa** ☐ **Mastercard**

Credit card number _____ Expiration date _____.

Signature (as it appears on card) ☐ **Bill me.** ☐ **Bill my organization.**

All business travellers should have reservations about where they sit.

For action

Please book my seat and arrange for

Window seat ☐

Aisle seat ☐

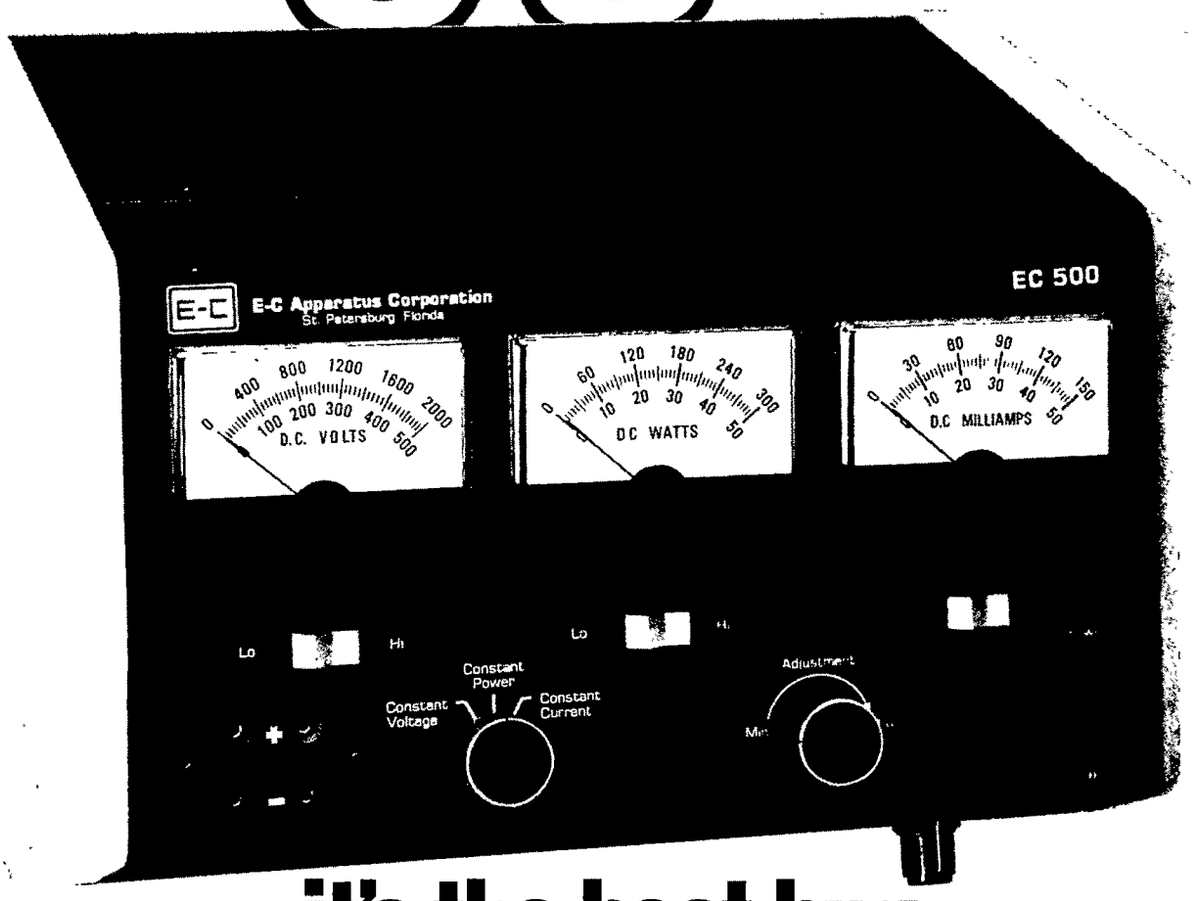
Smoking compartment ☐

Non-smoking compartment ☐

Swissair First and Business Class passengers can now select their seats when they make their reservations, even on the shortest flights. The request form above will help you to make sure whoever books your seat also arranges your seat reservation

Up to two weeks before departure we will accept your request for a seat by the window or on the aisle, in the smoking or non-smoking section.

When you make a reservation within two weeks of departure we will confirm to you a specific seat number (just as on the long-haul routes) We also assign seat numbers to reservations made more than two weeks in advance



Our Business Class now has separate check-in desks at 59 airports New Business Class lounges are being introduced and on B-747 and DC-10 long-haul flights we now offer a choice of three menus

With the care and attention that Swissair shows to its passengers it's little wonder that readers of Business Traveller magazine have voted us «best airline worldwide» three times since 1980 Most recently in 1984 With no reservations!

swissair

Reader Service No.03

At 65¢ a Volt...

...it's the best buy in Constant Power Supply

The $1295 EC500 was designed specifically to meet the need for a 2,000 Volt Constant Power Supply in special electrophoretic applications such as gel electrofocusing, gel sequencing, SDS gels, and standard slab and tube gels. Check these important features and benefits:

- maximum output: 2,000V; 150mA; 300W
- 3-mode control: Constant Power, Voltage, or Current
- optional voltage limit control for sensitive gels
- dual-range meters and high-low switching without effect on set points
- high voltage safety interlock
- positive electrical protection
- adapts easily to any cell

Star wars threat to ABM treaty

The Pentagon recipe for testing star wars technology without technically violating the anti-ballistic missile treaty is an artificial exercise likely to do more harm than good.

THE Jesuits earned themselves a bad name in the sixteenth century not only for their enthusiastic conduct of the inquisition but for their casuistry, their willingness to bend general rules to the circumstances of particular cases. The Jesuits are now much reformed, but the US Department of Defense is well on the way to succeeding to their odious reputation. The Pentagon's publication last week of its recipe for testing the viability of its star wars plans without violating the Anti-Ballistic Missile (ABM) Treaty with the Soviet Union (see p.3) is as fine an example of the jesuitical arts as there has been for years. In defence of its reputation, the department may say that it would never have dreamed of producing a document certain to give as many hostages to fortune if Congress had not required it to do so. But the Congress, whose love for star wars has yet to blossom, intended to offer Mr Caspar Weinberger, the US Secretary of Defense, a poisoned chalice; it would have been possible and prudent for him to have replied in terms less obviously calculated to undermine the ABM treaty.

What the Pentagon has done is to exploit the verbal inconsistencies of the treaty, as drawn in 1972 when the two signatories had no immediate cause to contemplate anti-ballistic missiles of other than the then conventional kinds. The chief interdiction (Article 1) is that neither side should deploy an ABM system except at the sites agreed (originally two, reduced to one in 1974). An ABM system is defined (Article 2) as one "currently consisting" (in 1972) of interceptor missiles, launchers for them and radars designed for use against the ballistic missiles rather than, for example, in air defence. The treaty says that none of these components should be deployed (except as specified) and makes plain that the interdiction applies not only to operational components but to components "undergoing testing". Elsewhere (Article 5), the treaty goes on to say that the signatories shall not "develop, test or deploy" ABM systems or their components which are based in space, in the atmosphere, on the sea or which are even movable on dry land — a point emphasized by the way in which the US delegation to the negotiations asked for, and got (in January 1972), an assurance that it would be a violation of the treaty if either party built a radar or a launcher for an intercepting vehicle that was not fixed on the surface of the Earth.

Violation

The bearing of these provisions on the way in which two parties to the treaty conduct themselves ten years later is ambiguous only to those who wish that it should be so. Most people will, for example, understand the string of verbs "develop, test or deploy" to indicate that development is the stage in a technical process that precedes testing, which is in turn a preliminary to deployment. But on that reading, the Strategic Defense Initiative will violate the ABM treaty once the feasibility of space-based missile defences has been investigated (by research) and the development of hardware has begun. The distinction between research and development is notoriously arbitrary, in civil as well as military industry, but because the star wars project will be increasingly concerned with demonstration projects (aimed at convincing the military, members of the Congress and, no doubt, US taxpayers) that the game is worth the candle, it is inevitable that the United States will soon be accused of having broken the treaty. "But it's only research", will be the cry, which will be defensible only on the hollow grounds that the US Congress has not by then agreed to provide funds for more than the research programme as now defined.

Sham

The notion that it will be possible to test the efficacy of novel kinds of missile interceptors without violating the treaty by pointing them at satellites rather than at ballistic missiles, or that tracking radars will be permitted if operated at reduced power, is similarly a dangerous sham. Although a successful demonstration that this or that new kind of ray gun can destroy a satellite will not, for example, also test the effectiveness of the target-tracking systems that would be needed for an operating defence against ballistic missiles, a few experiments like these could provide the knowledge on which full-scale missile interceptors based in space may be confidently designed. It should be even easier to extrapolate from observations with low-power radars or infrared sensors to the components needed for a defensive system. So there is every reason why the course charted in last week's document will provoke the Soviet Union to fierce protests. The Pentagon should also worry about the extent to which this advance advertisement of how it will break the spirit if not the letter of the treaty will generally undermine even the support of those who accept that the case for a programme of research on anti-ballistic missile defence can be sustained.

But how else to arrange that the feasibility of star wars can be tested? As it happens, the ABM treaty provides for a mechanism for doing just this — the creation of a Standing Consultative Commission to consider questions arising under or about the treaty, including (Article 13(d)) "possible changes in the strategic situation which have a bearing on the provisions of this treaty". By agreement, the commission was lumped together with that required by the first SALT agreement. This, no doubt, is the body to which the United States will turn if and when the time comes to raise with the Soviet Union the case for deploying some kind of system based on star wars. (This is also the forum in which the United States should have raised its proper doubts about the function of the Soviet radar, now being built near Krasnoyarsk in central Siberia, which is of a type whose siting there is forbidden by the ABM treaty.) It would be better to bite that bullet sooner rather than later, if only to keep some kind of relic from the days when arms control agreements seemed desirable and feasible.

But why bother? Nobody forgets that part of President Reagan's objective in embarking on star wars was his wish to make arms control agreements unnecessary. If the two superpowers (or even just one of them) could shelter behind solid missile defences, those endless visits to Geneva might be dispensed with. This argument (some say wish-fulfilment) is often heard in the United States; much less commonly in Western Europe. There are two difficulties. First, the United States is already engaged in arms control negotiations at Geneva (adjourned until later in the month). Second, the arguments that made the ABM treaty seem worthwhile in the 1970s are still valid even in the changed circumstances of the 1980s. The objective then was to protect the strategic retaliatory forces of each side from being rendered ineffectual. The proliferation of warheads and their increased accuracy has since made counter-force strategies

credible, but only just. But there is no reason to believe that a working star wars strategy is more easily realized. In short, and for as long as star wars remains a hypothesis to be tested, the need for arms control is as pervasive and as irresistible as President Reagan found during the first few months of his first term, in 1980.

But what is to be done about Soviet duplicity in this and other connections? At times, the US administration sounds a little like the lawyer whose defence of his client against a charge of murder takes the form of asserting that the client did not kill the victim and, then, that he did so in self-defence. The Krasnoyarsk radar is a sign (in the absence of argument to the contrary) that the Soviet Union has not been resting on its laurels, the anti-ballistic missile system around Moscow. It may also be the case that the Soviet Union is already hard at work on a research programme not very different in character from star wars itself, as the US administration claims, but that is irrelevant. The lesson that needs now to be learned is that, for as long as these schemes remain dreams (not necessarily illusions) they should not be allowed to affect policy. And if they are found feasible, their deployment will have to be discussed between the superpowers. Why not accept that now, not later? □

Fun made dull?

British school mathematics may be made worse by the government's recipe for reform.

WHAT should a young person know of mathematics? And how should mathematics be taught at school? From time to time, these questions recur almost everywhere, as some mathematicians would say. Under the idiosyncratic guidance of Sir Keith Joseph, Secretary of State for Education and Science, the British government has just embarked on yet another attempt to breathe new life into a jaded curriculum. Things may seem to have changed a lot (but not for the worse) since earlier decades, when British governments behaved as if they had no right to tell the local education authorities, which administer British schools, what should be taught, but only a kind of admonitory right to complain if teaching and (more often) other aspects of school life were hopelessly awry. But on this occasion, the government has decided to stiffen its exhortation to reform by the appointment of more than 300 full-time teachers whose sole responsibility will be to ensure that the pace of reform of mathematics teaching does not flag. Those with long memories should be forgiven for reminiscing about the early 1960s, when the government encouraged renewal of the mathematics curriculum, and when local education authorities showed willing by appointing people called "advisers" to help teachers change their teaching habits.

The objective now is also much what it was two decades ago, when the general opinion was that mathematics should be made to seem more like fun to students, that it should seem more "relevant" and that teaching should concentrate more on conceptual matters than on the learning of manipulative skills. (In Britain in the 1960s, although concepts such as that of sets made their way into the curriculum even of younger children, the "new math." never made quite the headway that terrified parents and some younger people in the United States.)

The occasion for the British government's new venture is a booklet by Her Majesty's Inspectors (of schools), called *Mathematics from 7 to 16* (HMSO, £2.00), which argues much the 1960s case for reform, but in a way that has predictably excited the British popular press. The most inflammatory passage is that which argues cogently that young people should be helped to use calculators as a means of carrying out calculations, not simply be allowed to use them for confirming the results of calculations done by other means, and which goes on to say that "long division.. should no longer be generally taught" and that "logarithms, as aids to calculation, are obviously redundant". The rumble of conservative protest has been palpable, but even radicals have been taken aback.

Conservatives should not be afraid that the end of their world has come. The new document is a recipe not so much for upheaval as for consolidation, even for consolidation about modest goals. This is not surprising, since the school inspectors have themselves relied on a study of school mathematics carried out by a government committee under Dr (now Sir) William Cockcroft and published three years ago. The inspectors echo that earlier plea that the mathematics taught in schools should consist of a central core of knowledge and understanding determined by the needs, interests and abilities of most students. On this view, mathematics at school is largely a utilitarian study. Even the section in the manifesto on "conceptual structures" is largely devoted to a sensible discussion of the reasons why students should appreciate the importance of estimating the results of calculations and approximating to them (or even to the insoluble problems of the real world). The document repeatedly urges that teachers should engage their students in practical work, but it is partly redeemed by its advocacy of open-ended questions in mathematics examinations.

The more serious objection to what is now proposed is its dullness, or its potential dullness in the hands and heads of many teachers. While the language of sets may, in the 1960s, have seemed a licence to some teachers to make algebraists of five-year-olds, the repeated exhortation to teachers now to bear in mind the practical needs of their students, especially to find jobs, will give many teachers the idea that mathematics should be turned into sophisticated mensuration. And while the inspectors' document repeats in humdrum language the belief that mathematics is more a part of modern life than of that of any previous age, it does very little to suggest to teachers that they should help their students understand how mathematics has become so powerful. Thus, absurdly, in spite of the inspectors' advocacy of computers as a means of making calculations, nothing is said about the benefits of understanding that even the simplest techniques for arithmetical manipulation (not to mention long division) involve the use of algorithms of a kind that also underlie computer programs. Fortunately, most teachers and many of their students already know better.

All is not lost, however, for the inspectors' prospectus is described as a discussion document, on which opinions will be welcome. Here are some complaints that the inspectors (and their minister) might usefully accommodate. First, because mathematics is as important as the document says, students of all ages and ability should be helped to understand how these circumstances have arisen (which argues for a little history) and why mathematics is so powerful (which argues for school-leavers knowing something of what can be accomplished by the calculus even if they have not learned to differentiate a simple function). Second, and consistently with the inspectors' utilitarian cast of mind, the curriculum should give students a general understanding of how problems of the real work are turned into problems in mathematics which, in practice, are soluble only exceptionally. Third, students need to have their spirits lifted by repeated demonstrations of the sheer neatness of much of mathematics, whence much of its power. But they need also to appreciate that, like other parts of science, mathematics remains unfinished business, as can be told at the earliest ages from the lack of an analytical formula specifying the prime numbers.

Can Sir Keith Joseph's band of advisers hope to accomplish all this? With luck, they will do much good, but there are two respects in which they will be handicapped from the outset. First, the mathematics teachers in British schools are too few and are also, too often, as unconfident of the material they hope to teach as are their students. The immediate remedy is for more in-service training, as the government agrees. The long-term solution may be unattainable, given the demand for people who can count in the economy at large. Second, a point which the government does not so far concede, there is a need for yet another deliberate attempt to redesign the mathematics curriculum by practical work by teachers working in the schools, not by edict from on high. Plainly, as things have turned out, what British school mathematics most needs is a flood of protest to the Senior Chief Inspector, Mr E. J. Bolton. □

Star wars

DoD makes a monkey of anti-missile treaty

Washington

THE Pentagon's Strategic Defence Initiative (star wars) office has produced the first detailed account of how it intends to carry out field tests of new ballistic-missile-defence hardware over the next five years without violating the 1972 Anti-Ballistic Missile (ABM) treaty. The explanation, contained in a report ordered by Congress when it approved the star wars budget last year, is likely only to inflame criticism that the Reagan administration is playing fast and loose with the treaty requirements.

Most of the field tests would be justified on the grounds that they do not involve "ABM components" or "prototypes of ABM components". The treaty does not prohibit the development of weapons to shoot down satellites, cruise missiles or tactical ballistic missiles. So when railguns and rocket-propelled projectiles are tested in Earth orbit in the early 1990s, their targets will be satellites, not missiles. The Department of Defense (DoD) report says that such tests will demonstrate the technology needed to defend space-based ABM battle-stations against Soviet anti-satellite weapons. But these technologies are also candidates for ABM systems proper, although DoD says only that the tests will "permit a decision to be made on the applicability of more advanced technology for ABM purposes".

Tests of lasers and space-based tracking systems, on the other hand, would be justified on the grounds that they will have only "limited capability". DoD says because the hardware to be tested is not advanced enough to operate in a fully fledged ABM system, it is not a "prototype". At least some of the limitations may be artificial. Thus a system to track Inter-Continental Ballistic Missiles (ICBMs) will not qualify as an ABM component prototype because it "may measure the signature of booster plumes, but not in real time".

Congressional critics of Star Wars were quick to point out, after the report was issued last week, that the Pentagon's reliance on the anti-satellite-weapon loophole is further evidence of the Reagan administration's opposition to any progress on a treaty limiting testing of anti-satellite weapons. Representative George Brown (Democrat, California) has called for a renewal of a congressional ban on further anti-satellite testing. He also called plans to test star wars hardware against satellites a "circumvention of the spirit of the ABM treaty".

An analysis by legal scholar Abram Chayes of Harvard University reaches a similar conclusion. He says that attempts to develop star wars technology under the label of anti-satellite or anti-tactical-ballistic-missile programmes are "legally disingenuous" as well as technically costly. Chayes points out that the course charted by the Reagan administration will inevitably generate disputes over its legality under the treaty and argues that, instead of being simply a "research" programme that will leave open a decision to renounce the treaty in the mid-1990s and proceed with deployment, star wars as now conceived may make that decision a foregone conclusion.

The DoD report suggests two other ways to get around the provisions of the ABM treaty. The treaty specifically allows field testing of fixed land-based ABM systems or components. This was the administration's justification for the experiment last year in which an interceptor launched from Kwajalein Missile Range in the Pacific hit an ICBM launched from White Sands Missile Range in California. Several further tests of both radars and interceptors is planned under this provision.

The report also hints at a more drastic way to evade the treaty's constraints. Noting alleged Soviet violations of the treaty, the report says "we do reserve the right to respond to those violations in appropriate ways, some of which may eventually bear on the Treaty constraints as they apply to the United States".

Star wars

Academics sign on for research

Washington

WHATEVER their first reservations, US universities seem to be having no scruples about cashing in on President Reagan's star wars programme of ballistic missile defence, known formally as the Strategic Defense Initiative (SDI). The SDI organization's innovative science and technology office, which will spend 5 per cent of the star wars budget, has started to award multi-million dollar contracts to university/industry consortia for basic research with possible applications to missile defences. The office, established only last November, will soon have committed over $50 million for basic research. More than 50 US institutions will be working on basic star wars research within the next few months.

The three consortia already named by the innovative science office will be working on non-nuclear power sources suitable for space-based systems ($19 million over four years), optical signal processing ($9 million over three years) and advanced composite materials ($15 million over three years).

Smaller institutions are not being left out. Besides such well-known research establishments as the California Institute of Technology and Massachusetts Institute of Technology, the consortia include, for example, the University of Texas at Arlington and the University of Alabama at Huntsville.

Applied (as distinct from basic) research, which accounts for the greater part of the SDI budget, is being carried out in-house in government laboratories or in industrial companies; several hundred SDI research contracts have already been negotiated. SDI has a total budget of $26,000 million over the five years from 1 October 1984.

The director of the innovative science and technology office, James Ionson, says he has no illusions about the magnitude of the technical problems confronting SDI, but he is convinced that solutions to many of them will eventually emerge from speculative basic research of the sort supported by his office. According to Dr Ionson, many ideas that at first "seemed crazy" have now demonstrated their potential and will be included in the SDI effort.

All the basic research supported at present through Ionson's office is unclassified, but the classification requirements for SDI research are under scrutiny by the Department of Defense (DoD). Ionson is confident, however, that DoD's policy of relying on classification alone to control on-campus basic research will be maintained.

The recent disruption caused by DoD at a meeting of the Society of Photo-optical Instrumentation Engineers (see *Nature* 18 April, p.569) raised the possibility that DoD might in future make more use of Export Administration Regulations to restrict the flow of sensitive technology abroad. According to Dr Ionson, use of such regulations is most likely when commercial interests become involved but each case will be considered on its own merits.

Export regulations will undoubtedly be the subject of politically-delicate negotiations if overseas institutions participate in star wars research, because foreign governments will want to ensure that they receive the benefits of technology spin-off. But Defense Secretary Caspar Weinberger has still not given the formal go-ahead for foreign collaboration.

Among the major research threads supported through Dr Ionson's office is optical systolic computing, which could bring within reach the enormous computing power that would be needed for a star wars defence. Ionson is also looking at the possibilities for molecularly engineered dielectrics for capacitors, plasmoid weapons and the protection of satellites in radioactive environments by pumping out the Van Allen radiation belt.

Japanese Science Council

Elected body goes out fighting

Tokyo

THE Science Council of Japan (JSC)'s final meeting as a directly elected body ended last week in the liberal tradition it has long upheld. One of its final actions was to call on the government to improve the status of female scientists.

Since 1948, Japan's unique "Parliament of Scientists" has provided a means for Japanese research workers to express their opinions to government. Every three years, 210 representatives from every branch of science have been elected to the council by a direct vote of more than 200,000 of Japan's scientists. Committees organized by the council have been instrumental in shaping the grants policy of the Ministry of Education, Culture and Science (MESC), in pressing for the establishment of new institutes in areas where they were thought most needed and in upholding scientists' rights. The president of JSC is automatically a member of the Council for Science and Technology, the highest science policy-making body in the land, and thus has the ear of the Prime Minister.

In recent years, however, things have not always gone smoothly between the government and JSC. As MESC relied more and more on advice from its own internal science council, JSC came to see its influence on grant policy decline. In turn, voters became apathetic and, as the government sees it, the council came to be influenced more by those with a "political" axe to grind than by those concerned with purely scientific matters. Apparent opposition to nuclear power by JSC particularly irritated the government.

In 1982, the government, which pays all JSC's expenses, finally demanded reform, and when it proved hard to agree, reform was forced on JSC. The result is that from now on, members will no longer be directly elected but will instead be appointed through the scientific societies (see *Nature* **305**, 361; 1983).

The call to improve the lot of women scientists stems from surveys carried out by JSC over the past few years of the special difficulties encountered by women scientists. It was plain that few women were reaching the top posts: there are no female full professors in the science faculties of the principal universities, few women among the laboratory chiefs of government research institutes and a relatively small percentage of women entrants to science courses in top universities.

These observations mirror problems for women in Japanese society as a whole. The average salaries of women are barely half those of men, not so much because of different rates of pay for the same job but because women generally occupy lower positions. Surveys show that three-quarters of companies hiring university graduates (who will eventually go into management positions) hire only men. Of those that do hire women, half will not allow them any possibility of promotion and two-thirds will not give them access to training or education programmes. "Retirement" at marriage is a not unusual condition of work.

JSC's subcommittee on the status of female researchers carried out its own survey on the position of women scientists after an earlier plea, in 1977, failed to persuade the government to conduct a proper survey. Some 2,000 women scientists and 1,400 male scientists were asked to complete questionnaires, and the results confirm women's poor promotion prospects.

Taking into account academic record, the chances of a woman becoming a full professor appear much lower than those for a man. Most women who successfully complete their doctorates cannot hope to gain a post higher than assistant lecturer and the higher they go, the more difficult further promotion becomes. Professor Katsuko Saruhashi, one of the few women to reach laboratory director level (within the government's Meteorological Research Institute) and a veteran campaigner for the rights of women scientists, says it is bad for the nation not to make use of women's abilities and that what is now being demanded is a proper government survey that could be used to make the reforms that would improve the position of women.

On the government's recent record, however, it is unlikely that her wishes will be fulfilled. The Diet will vote next month on an equal opportunities bill intended to give the government an opportunity to ratify the United Nations Convention on the Elimination of All Forms of Discrimination Against Women. The bill has, however, been thoroughly emasculated by employers' representatives, and apart from abolishing some old restrictions, such as those that prevent women working late at night, it provides little in the way of new rights. There are so many loopholes in the bill that it would be almost impossible for legal action to be taken on its provisions. Although it calls for women to be given equal treatment to men in job recruitment, allocations and promotion, there are no substantial penalities for non-compliance.

Romania

Nuclear power in the distance

PRESIDENT Nicolae Ceaucescu of Romania last month cut short an official visit to Canada after he was told that he could not visit the Pickering nuclear reactor plant because of a labour dispute. He did, however, visit Hydro-Quebec's nuclear power station at Becancour, which uses Candu reactors, similar to those the official handouts somewhat misleadingly referred to the "two plants now under construction in Romania".

Romania signed contracts for the purchase of two Candu reactors in 1978 and 1981, and has options on up to eight more. But the deal has been beset by difficulties; firstly by Romania's lack of hard currency, which makes necessary a countertrade (barter) arrangement, and then because the Romanians insisted on dealing with all the Canadian subcontractors separately, instead of negotiating with Atomic Energy of Canada Ltd (AEC). As a result, although the proposed site at Cernavoda in Romania is being prepared to receive five reactors, hardly any equipment has yet arrived from Canada. The 4,500 Romanian on-site workers are simply carrying out preliminary construction work, including the containment buildings for the firt two Candus. (Containment buildings are a rarity in East European power stations; Soviet doctrine considers them a Western device to raise costs, although the Hungarians insisted on having them for their Soviet-produced reactors at Paks.)

Mr Ceaucescu is clearly anxious to get the Candus installed as soon as possible. Although Romania is an oil-producing country, heavy investment in the petrochemical industry during the 1970s has turned it into a net energy importer. By the early 1980s there was an energy crisis, and the severe winter of 1984–85 meant prolonged power cuts for both domestic and industrial users and a ban on all private motoring. Not surprisingly, the Party daily, *Scintea*, on the eve of the President's visit to Canada, hailed the Candu as the answer to Romania's energy problems.

The project is, of course, badly behind schedule. The first two Cernavoda Candus were meant to be operational by 1985; instead, the first major equipment will not be delivered until the autumn, and the primary cooling pumps, from Bingham Willamette of British Columbia, will not be delivered for two or three years.

But Canada too needs the Romanian contract to save jobs in its nuclear industry. Although the existing deals provide for Romania gradually to absorb Canadian technology and eventually to build its own Candu reactors (paying a royalty on the first fifteen), the Canadian content of the third and fourth Cernavoda reactors, though less than the first two, would still be significant. Furthermore, after prolonged negotiations, the two sides have signed a third-market contract, by which (subject to Canadian requirements on non-proliferation), Romania would cooperate with Canada in selling Candu reactors to other countries, particularly in the socialist and non-aligned blocs where Romanian contacts could be particularly useful.

Vera Rich

European Communities

More attention for basic research?

Brussels

Karl-Heinz Narjes, research commissioner of the European Economic Community (EEC), seems to be edging towards a more balanced programme of Community research. At an informal meeting of research ministers in Rome last week, he urged that industrial competitiveness should dominate the programme to the exclusion of research in fields with fewer technological benefits.

As things are, the EEC programme is dominated by schemes for improving European competitiveness vis-à-vis the United States and Japan (notably the ESPRIT and BRITE programmes). But Narjes stressed last week that there are "yawning gaps" in agricultural research, for example, especially the reduction of surpluses, and the improvement of food quality and of animal production. There is no research at all in fisheries and aquaculture, he said.

The interim report on the current framework programme, which will run until 1987, also talks of a serious imbalance between nuclear and non-nuclear objectives, and says that schemes for stimulating cooperation and interchange have been more "gradual" than expected.

The aim of the presentation was to start EEC research ministers thinking about their priorities for future Community research on the eve of the review of the framework programme, planned for the second half of 1985. That debate will be preceded by a comparison of national and Community scientific policies by the COPOL (Coordination of National Policies) group meeting in June 1985.

The Commission's own proposals for future areas of research include health care and technology, the management of energy resources, training, European cooperation, the mobility of researchers (inside and outside the Community) and the more effective use of scientific equipment. Moreover, the Forecasting and Assessment in Science and Technology Group, whose preliminary conclusions are due in mid-1985, wants more research of an economic character into companies and services.

Whether ministers will accept these proposals will depend not least on what they are prepared to spend on research out of the Community budget and their own resources. By March 1985, the activities of the current programme had cost 2,685 million European Currency Units (ECU, 1 ECU = £0.60) out of a total of 3,750 million ECU budgeted until 1987 — three per cent of the total Community budget. In 1984, ministers committed themselves to increase research funding. Both Jacques Delors, the president of the Commission, and Mr Narjes would like to see that figure doubled for the second framework programme covering 1988-1991/92.

The meeting in Rome also gave ministers a foretaste of the agenda for the formal EEC research council scheduled for 4 June in Luxembourg.

- **Telecommunications research.** The European Commission is keen to get a speedy decision on its proposals for research in advanced communications in Europe (RJCE, see *Nature* **314**, 209; 1985) but the United Kingdom, France and West Germany are sceptical, asking for a clear definition before embaking on research.
- **Tritium-handling laboratory.** To support the thermonuclear fusion programme, EEC has agreed to build a laboratory at the Joint Research Centre at Ispra in Italy, but Britain and France continue to doubt its siting and timeliness, given that the Next European Torus (NET), for which the tritium would be needed, will not be ready until the 1990s, and that the site for that machine has not yet been chosen.
- **European Synchrotron Facility.** In exchange for its agreement to the proposed site at Grenoble, Denmark is seeking a marine research institute in its own country.
- **Initiative for Research in Informatics applied to Society (IRIS).** This proposal, put forward by the Italians in Rome, would encourage companies to develop new products and social services in fields such as medicine and agriculture. The proposal has been greeted with scepticism by the United Kingdom, but the Commission has agreed to a preliminary study.

Ministers also discussed proposals by the European Commission for greater control of state aid in the member states. Such control over national research programmes would be particularly unwelcome in countries such as the United Kingdom, France, West Germany and Italy.

Anna Lubinska

French research

CNRS to concentrate resources

THE French national research council (CNRS) is to devote 40 per cent of its resources to twenty newly defined "strategic objctives", according to the CNRS 5-7 year plan published last week. The twenty disciplines include many fundamental subjects, such as nuclear and particle physics, but these are sometimes combined in significant new associations. Thus, the "sciences of the Universe" combine in one objective with particle and nuclear physics. Other objectives specify boundary-breaking explicitly, such as that named as "the interaction between and chemistry biology". It has long been a passion of the CNRS director Pierre Papon to forge unity among the highly divided disciplines in France; the CNRS council seems now to have given him the hammer and anvil he needs.

The new objectives also stress long-range applied science, such as Earth observation from satellites (in anticipation of the launch of the French SPOT satellite later this year), process engineering, biotechnology and so on, but Papon said last week that their selection is not a threat to the basic sciences. Many of them, he said, are in any case basic science and "it is not a major problem to defend basic science in France".

According to Papon, the real objective of the CNRS "list of 20" is "to unify science". He says he was struck, during a European tour last year, by the many links between chemistry and biology departments in Britain, whereas there is just one such department in France. Unification of disciplines is also more advanced in Sweden and Switzerland. Research in France is more fractured than elsewhere, though many modern scientific problems are multidisciplinary.

Mobility, both among disciplines and geographically, is poor, but Papon says CNRS is working with the ministry of research and technology to solve many purely administrative and practical obstacles, such as finding a job for a spouse. Last year there was a growth of some 15 per cent in the number of CNRS researchers moving into industry for a spell of three years or more. This might be "slow progress", but there is a "psychological problem" said Papon. Last year, one in two hundred CNRS staff made a move to industry. "It would be nice to double the figure."

Robert Walgate

Areas of research

THE research areas that CNRS will now emphasize are:

- **The universe, atomic nucleus and elementary particles (some of the costs of these disciplines are borne outside CNRS).**
- **Mathematics.**
- **Optics.**
- **Materials sciences.**
- ***Filière électronique* (science applied to the microelectronics industry).**
- **Plasma physics and nuclear fusion.**
- **Energy and thermodynamics.**
- **Process engineering.**
- **New methods in earth sciences.**
- **Dynamics of the ocean systems.**
- **Remote sensing.**
- **Continental water.**
- **Understanding chemical reactions.**
- **Chemistry-biology interaction.**
- **Biotechnology.**
- **Neurosciences.**
- **Sciences of evolution.**
- **Sciences of communication.**
- **Employment, work and technology.**
- **Urbanism, architecture and society.**
- **Large scientific equipment.**

Twinned-centre jumps legal gun

New Delhi

DESPITE legal and other hurdles, the United Nations Industrial Development Organization (UNIDO) is trying hard to put its International Centre for Genetic Engineering and Biotechnology (ICGEB) on an operational footing this year. The sixth meeting of the ICGEB preparatory committee held last month in New Delhi has decided to launch the centre's scientific activities without waiting for the ratification of the ICGEB statutes by member countries

So far, 36 nations have agreed to be members of the first international biotechnology centre, but only Iraq has ratified the statutes. Mr Adolfo Teylhardat of Venezuela, chairman of the preparatory committee, says the statutes must be ratified by at least 24 countries before ICGEB becomes a legal entity

UNIDO mooted the idea of the centre in 1981 with the aim of bringing the benefits of biotechnology to bear on problems unique to the developing world. By a decision in 1984, ICGEB is to have two components, one located in New Delhi and the other in Trieste, Italy. The host countries have yet to ratify the statutes and finalize the agreements with ICGEB.

These legal hurdles are not expected to hold up the activities of the centre. The New Delhi meeting, attended by 25 countries, decided formally to begin the centre's work with a workshop on plant biotechnology in New Delhi in September. This will be followed by another workshop at Trieste on a topic yet to be decided.

In establishing ICGEB, UNIDO is being guided by an panel of eminent scientific advisers (PSA). One of the panel's suggestions, based on the experience of the Salk Institute in the United States, was to hire between five and ten distinguished scientists to serve as non-resident members of the faculty of the centre This suggestion, though on the agenda, was not followed up at the New Delhi meeting. Nor was any decision taken on the selection of a director for the centre. Taylhardat said that ICGEB is looking for a single director for its two components who would be "a scientist of world repute with managerial experience" Selection has been deferred until the next meeting of the preparatory committee in Havana in November.

A major recommendation of PSA is that excellence and not nationality should be the basis for selection of the director and other senior staff, who need not necesarily be from member countries. Except for Greece, Italy and Spain, most of the ICGEB members are developing countries with little infrastructure or trained manpower for genetic engineering research. For this reason, most of the staff is initially expected to be from developed nations.

The ICGEB statutes provide certain immunity and privileges to internationally recruited staff that will not be available to the locally recruited scientists. This, together with the proposed discriminatory salary packages ($50,000 and above for international staff) may create problems, Indian scientists fear. India has made it clear that its contributions to the centre in New Delhi would not cover the salaries of such international staff members, the cost of which will be met with funds from Italy.

Although no countries except the hosts have pledged funds, UNIDO says the operation of ICGEB for its first 30 months is assured by offers of a total $24 million by India and Italy. ICGEB's operational cost for the first five years is estimated at $47.8 million. It is hoped that the balance will be covered by initial and yearly contributions from members and others. Laboratory facilities are yet to be set up in Trieste or New Delhi. India has allocated $4.3 million for 1985-86 for permanent facilities on 25 acres of land and temporary laboratory space in the Jawaharlal Nehru University.

Under existing arrangements, the New Delhi component of ICGEB will conduct research on biotechnology applied to agriculture, human and animal health whereas the Trieste half will focus on industrial microbiology — the conversion of biomass into fuel, bio-recovery of hydrocarbons and protein engineering. Trieste will have full facilities for developing industrially viable technologies based on genetically manufactured organisms, for scaling up technologies developed in New Delhi and a central computer facility.

By the time the centre reaches full operating capacity, each site will have a team of 30 scientists, 20 postdoctoral fellows, 30 technicians and 30 trainees from developing countries. According to Taylhardat, it will serve as an international channel for the flow of information on biotechnology from industrialized to developing nations. A gene bank containing genetic stocks and information is also planned.

Taylhardat said that ICGEB will also be the centre of a network of affiliated regional and national research institutes for biotechnology research. The New Delhi meeting considered requests for affiliation status from ten countries, including Egypt and China **K.S. Jayaraman**

US science budget

Deficit-cutting means freeze

Washington

RESEARCH is unlikely to emerge unscathed from Congress's efforts to reduce the federal budget deficit despite its relatively privileged position in the Reagan administration's list of priorities. The Senate is considering proposals to hold spending on various scientific and space programmes at 1985 levels. The agencies affected include the National Science Foundation (NSF), the National Aeronautics and Space Administration (NASA) and the Department of Energy. The House of Representatives, for its part, has refused to authorize the administration's proposed 4.4 per cent budget increase for NSF. Earlier this month, the House of Representatives similarly refused to authorize an increase for NASA (see *Nature* 11 April, p.488).

The proposal before the Senate to freeze spending on general scientific and space research, known as function 250, is part of the deficit-reduction package agreed last month between Senate Republican leaders and the White House, which was still being debated last week. Were the package to be adopted by the full Senate, it would become politically almost impossible for Senate committees to authorize budget increases for scientific agencies

The House action in freezing NSF's budget would keep the authorization at $1,501 8 million. The $67.6 million saved would come from research ($58.3 million) and from the US Antarctic programme ($9.3 million). The House Science and Technology Committee had earlier recommended going along with the President's proposed budget of $1,569.4 million, but during the debate in the House, committee members offered the cut, which was accepted by a large majority.

The House bill (HR 1210) would also transfer to the director of NSF the authority to appoint assistant directors. In the past, there have been long delays in filling these posts because of the requirements that assistant directors be appointed by the President and then confirmed by the Senate. The bill also enjoins the NSF to place "emphasis" on acid rain research. The Senate has not yet voted on the NSF budget authorization, but the Commerce Committee, one of two Senate committees vying for jurisdiction over the foundation, last week recommended a budget increase broadly in line with the administration's request. The Labor and Human Resources Committee will tackle the NSF budget later this month, after which the Senate will vote; a conference committee to resolve differences with the House is likely.

Arguments in the authorization committee are partly political posturing, as it is the appropriations committees that finally decide what money goes where. The Senate has been unable to pass an NSF authorization bill for the past four years, and few have missed it; if, however, such a bill were passed by both Houses that implied a budget freeze, it would be technically difficult and politically risky for the appropriations committees to fund a budget increase. **Tim Beardsley**

Australian science

Plans laid for new lobby

Canberra

AUSTRALIAN scientists and technologists have taken the first step towards the formation of their own national lobby group, to take its place alongside the others crowding the political landscape. Almost every other interest group seems to have a lobbying arm. But Australian scientists, although producing two per cent of the world's published scientific literature from a population base comprising less than one-half of one per cent of the total, have only now realized that a performance-enhanced mousetrap, say, will not automatically be taken up by industry, or even recognized by the media, let alone by politicians. This is why, with a few notable exceptions, scientists are a fugitive breed in Australia, misunderstood when not actually invisible. Last week's nucleation at a meeting in the Australian Academy of Science of a body to lobby government and spread the good word generally may help to rectify the situation.

The spur has been the August 1984 federal budget, in which publicly supported science was cut back by five per cent. With recruiting among academics and in the Commonwealth Scientific and Industrial Research Organization (CSIRO) already at a standstill, it began to look as if even scientists holding permanent jobs would have their research hindered. An *ad hoc* group of eight scientific societies expressed disquiet about the cuts. The Academy of Science established a 16-member National Committee for the Promotion of Science and Technology under the chairmanship of Professor Max Bennett, a neurobiologist from the University of Sydney.

The immediate outcome was the National Meeting of Concern on Science and Technology at which the elected leaders of 68 scientific and industrial societies and two academies representing about 80,000 members voted to elect an interim federation committee. That committee's first task is to explore the setting up of two secretariats, one of which will be a small professional lobbying group based in Canberra to facilitate communication between government and the scientific community, especially at budget time.

The other committee (probably based in Sydney), will provide a science and technology information service modelled on the Media Resource Service of the US Scientists Institute for Public Information. Through it, people in the news media, education and politics throughout Australia would be put in touch with experts for comment on scientific matters. The twelve-member interim committee, under the chairmanship of Professor Fred Smith, a physicist at Monash University, is due to report in six months.

A mood of optimism pervaded the meeting, but there were objections that political consensus may be difficult to achieve between academic, CSIRO and industrial scientists, particularly because the specialist societies (some with their own lobbying apparatus) differ greatly in size.

The federal Minister for Industry, Technology and Commerce, Senator John Button, said that, although he welcomed the possibility of discussions with such widely representative groups, not all basic research could be convincingly sold as seed corn for the future. In the interests of industrial restructuring, he said, public financing "may not be just where you are used to it being".

The Minister for Science, Mr Barry Jones, was absent from Australia during the meeting, but in February this year something was salvaged from the 1984 budget wreck in the form of one of his favourite projects — the Commission for the Future.

The aim of the new body is also to raise public awareness and debate about science and technology, especially about the ways in which technological change will affect the lives of ordinary people, and the choices they must make in education and employment. The commission is headed by Mr Philip Adams, an advertising executive and all-round pundit, who is an old friend of Mr Jones.

The scene is set, then, for the emergence of science (and some scientists) from the shadows where they have languished politically for so long. Noting how badly the job of advocacy has been done in the past, Professor Smith says that, realistilly, a major impact may not be felt for five years. **Jeffrey Sellar**

Famine

Remedy not by bread alone

Anaheim, California

THE more equitable distribution of available food supplies is not, by itself, the best way of avoiding famine. This is what a gathering of biologists was repeatedly told last week. And so it is a matter of urgency that biologists should pay more attention to the prediction, the causes of onset and the prevention of famine.

Organized by Dr Barry Bloom of the Albert Einstein College of Medicine, the symposium was belatedly and exceptionally tagged onto the 300 or so sessions already jamming the programme of this year's meeting in Anaheim of the Federation of American Societies for Experimental Biology (FASEB). Bloom, an immunologist with a special interest in leprosy, was prompted to organize the symposium by the present African famines. "We have learned so few lessons", he says, "that each new catastrophe tends to repeat some of the classic errors from the past."

One priority in research should be to develop criteria for predicting famines in time to prevent them. "In most circumstances, one is likely to have one group of people politically or emotionally interested in asserting that the situation is worse than it is and another arguing the opposite", says Bloom.

That theme was taken up by John Mellor of the International Food Policy Research Institute in Washington, DC, who argued that if more famine-prone countries had democratic governments and a free press, we might learn of problems in time to prevent them. Foreign aid must be channelled into transportation systems so that food ca be distributed, he said, and into the training of an elite of agricultural personnel. The priority for scientific research should be the mounting of a green revolution in Africa.

Although confident that scientists could produce the means for such a revolution, Dr Robert Goldman, of the plant biotechnology company Calgene, wondered if it would be put into effect. The science that fuelled the green revolution that saved India and Mexico from famine was developed in the public sector and applied without profit. Now that the impetus for plant improvement has passed to the private sector, particularly agricultural biotechnology companies, the developing countries may be less able to win benefits.

Famine is, in any case, the end result of a chronic condition of malnutrition. Eight hundred million people worldwide are calory-deficient, and "it seems likely that whole societies have been forced to adapt to this", says Dr Neville Scrimshaw of the Massachusetts Institute of Technology. Adaptation means reducing physical activity, which can have severe social consequences. Less obvious deficiences of iron, vitamin A and iodine are widespread, debilitating and make people more prone to infections which, in turn, can exacerbate malnutrition.

The downward spiral that ends in famine is best broken by immunology, in the opinion of Stephen Joseph of UNICEF. Calling for more research into both vaccine development and the inter-relationship between immunity, nutrition, infection and growth, he said that scientific research must go hand in hand with improved management of preventive programmes and better education of those who should benefit.

After the symposium, Dr Bloom complained that no more than 200 people had attended. Up to 15,000 people were expected to register for FASEB, and although the famine symposium was held the evening before the full meeting got under way, 2,000 people turned up next day at a lecture on the molecules involved in lymphocyte activation. **Peter Newmark**

AIDS

Undesirable import to Japan

Tokyo

WITH Japan under pressure to increase imports of US goods, it is ironical that one product Japan imports freely from the United States may have brought acquired immune deficiency syndrome (AIDS). According to last month's *Taisha*, the Japanese medical journal, two now-dead Japanese haemophiliacs were killed by AIDS, probably by infected blood plasma, almost certainly imported from the United States.

One of the victims, aged 48, died in July 1983 and the other in November last year, aged 62. The victims, the first from AIDS in Japan, showed an extraordinary loss of immunity, and the presence of antibodies to the virus HTLV-III has been confirmed.

No cases of AIDS have yet been reported among Japan's homosexual community, but a confirmed Japanese homosexual now living in the United States who returned to Japan in mid-January was diagnosed as an AIDS sufferer. The AIDS Research and Study Committee of the Health and Welfare Ministry says there is little chance that the man infected others in Japan.

The emergence of AIDS cases among Japanese haemophiliacs seems to be attributable to Japan's almost insatiable demand for US blood plasma. Despite one of the highest rates of blood donation in the world, Japan depends on the United States for nearly 90 per cent of the plasma it consumes, amounting to 300,000 litres a year. Demand for plasma-protein fractions and blood-component preparations is rising, for the latter by 15 per cent a year.

So why is Japan so dependent on blood plasma imports when there were more than eight million blood donations last year? Officials at the Health and Welfare Ministry explain that donors in Japan give only 200 ml of blood on each occasion, compared with about 400 ml in other countries. But a Japan Red Cross official says that in the United States in 1982, just under six million donations of about 450 ml were made, suggesting that *per capita* blood donation in the two countries is similar.

Dependency on blood imports is in part a legacy of the system before 1982. Blood donations were then saved almost exclusively for the use of the donor himself, who would resist the idea of volunteering blood for others, probably for the reasons that also make Japanese reluctant to donate organs for transplant (see *Nature* **313**, 338; 1985).

The Health and Welfare Ministry's planned solution of this vexing problem is threefold. First, Japanese donors will be asked to donate 400 ml instead of the present 200 ml. Second, plasmaphoresis, which separates the plasma and returns red cells to the donor, will be more widely used. Third, doctors will be asked to avoid unnecessary wastage of plasma. In the meantime, however, imports will continue and there are no plans to screen imported blood for AIDS.

All of this must provide small comfort for Japan's haemophiliacs. The article in *Taisha* even reports that the blood of 23 out of a random sample of 50 Japanese haemophiliacs contained antibodies to the virus HTLV-III, which suggests that a large proportion of Japan's 5,000 haemophiliacs may have already been exposed.

Even if imports stopped, there would be another danger. Drs Kazuo Ohkouchi and Hiroyuki Sato of Kyushu University in southern Japan have now shown that the virus HTLV-I, which causes adult T-cell leukaemia (ATL), can be transmitted by blood transfusion. ATL is endemic in southern Japan, where approximately 20,000 carriers are found among blood donors each year. Dr R.C. Gallo, chief of the tumour cell laboratory at the US National Cancer Institute, has even suggested that an AIDS-like epidemic of ATL may be imminent. Clearly, the management of blood supplies in Japan is a matter that in future will come under increasing scrutiny by the eyes of the world.

David Swinbanks

ESA, Japan agree on participation in planned US space station

EUROPE formally agreed last week to join the United States in the development of a space station, but details such as who spends how much on what remain to be decided. The European Space Agency (ESA) will now sign a memorandum of understanding with the National Aeronautics and Space Administration (NASA) which requires that the design of the space station, with costs and commitments, must be ready by the end of 1986. This phase of the work will cost ESA $65 million.

NASA has already signed a similar agreement with Canada, which aims to provide robot-servicing equipment at a cost of some hundreds of millions of dollars, and is due to sign another with Japan this month (see above).

The European contribution may finally be some $2,000 million, which should buy a pressurized module that could be used as a manned laboratory (called Columbus), a number of free-flying payload carriers for both low-inclination and polar orbits, a servicing vehicle and a resources module that could provide both the pressurized module and the payload carriers with electric power, cooling and stabilizing systems.

These housekeeping elements have been included in ESA's plan at French insistence, and would enable the European modules to fly separately from the US space station if necessary, although (for the moment) Europe would still have to rely on the US space shuttle to put its astronauts into orbit. France, however, has plans for a mini-shuttle (Hermes) and in Britain, British Aerospace has described the concept of a horizontal take-off and landing spacecraft (HOTOL). Either of these could ultimately provide people with independent access to space.

There are more immediate issues still to be resolved. US fears that technologies transferred to Europe would leak to the Soviet Union engender corresponding European fears about access to US science, technology and data. There are also the issues of who pays the still unknown maintenance and running costs of the station, the legal framework for deciding patent rights arising from work on the station and the management and decision-making structure of the enterprise.

Robert Walgate

Tokyo

JAPAN has decided to take part in the US project to build a manned space station. James Beggs, head of the US National Aeronautics Space Administration (NASA), who has made earlier trips to Japan to promote the space station, will return to Tokyo for the signing on 9 May of an agreement between NASA and Japan's Science and Technology Agency (STA).

The initial agreement will cover a two-year period of design work and will provide Japan with technical information on the space station. STA is refusing to release details of the budget until after the signing, but it is known that some 1,400 million yen ($5.6 million) has been earmarked for the project in this year's budget.

Informally, a consensus seems to have been reached that Japan should take the opportunity to master new technology and build one whole experimental module of the space station. A subcommittee of STA's Space Development Committee has recommended that it consist of three parts: a pressurized cabin ten metres long and four metres in diameter for use in experiments on new materials and new pharmaceuticals more easily produced in gravity-free conditions, a service platform for testing of telecommunications equipment in outer space and a storage cabin. Total design and construction expenses are likely to exceed Y200-300 thousand million million ($800 million).

Industry has already expressed considerable interest in the space station and several large corporations, including Mitsubishi, Mitsui, Sumitomo and Fuyo, are now merging their respective study groups to find the best way to win commercial advantage from the station. **Alun Anderson**

Popularization

Royal Society asks for more

THE Royal Society, the premier British scientific society, is to be given a hefty nudge towards the popularization of science, to judge by a meeting on the "public understanding of science" held under the auspices of the British Association for the Advancement of Science in London on Monday.

The meeting was convened by Sir Hans Kornberg, British Association president, to provide a debating forum for the Royal Society *ad hoc* committee on public understanding. And while many old chestnuts were brought out on Monday and re-roasted, Dr Walter Bodmer, chairman of the Royal Society committee, used the occasion to demonstrate his committee's determination that its work would not gather dust on any shelf.

The need is certainly great. In Britain, on the whole, there is little sign of a scientific lobby, nor of any determined effort by the universities or research councils to educate or even entertain the public in science. Bodmer and his committee wish this situation to change, and by starting at the Royal Society, traditionally a somewhat austere institution whose motto is "*nullus in verba*" (nothing in words) they are certainly taking the bull by the horns. Dr Bodmer hoped the Royal could provide a lead which others could follow.

During Monday's meeting, Dr Bodmer, director of the Imperial Cancer Research Fund, received support from many quarters both in the media and in government. Sir Robin Nicholson, chief scientist in the Cabinet Office, claimed it is now almost impossible to find a political issue without scientific or technical content, and that "90 per cent of his time" is used in advising government on these matters (and only 10 per cent on science itself). Science and technology are now central to many foreign policy issues, said Sir Robin, in the way that international trade took centre stage 25 years ago. But "the attention span grows shorter as one gets older" so now cabinet ministers can only cope with five-minute briefings or three pages of A4. The same is true of leaders of industry. But scientists, for good reasons, are trained to write *in extenso* and giving equal weight to many ideas. This is completely at odds with what is needed in government, or in the press.

Dr Bodmer was keen to affirm that he would like the Royal to play an active role in getting scientists to approach the media. A member of the science advisory panel to the British Broadcasting Corporation (which, incidentally, reckons it shows four times as many science hours in proportion to output as does US television), Bodmer is also taking seriously advice to expand the Royal Society's programme of science briefings, to institute rapid press conferences on scientific issues behind and in the news, to run deeper, background seminars on scientific matters, and to produce detailed condensed briefing documents for journalists.

On a warning from Sir James Gowans, chairman of the Medical Research Council, that such exercises cost money and a lot of time, Dr Bodmer said he hoped the Royal Society would be able to find backing "if not from government" from industry — which should benefit in the long run from better public knowledge. His committee's report is due in a few months' time. **Robert Walgate**

Animal experimentation

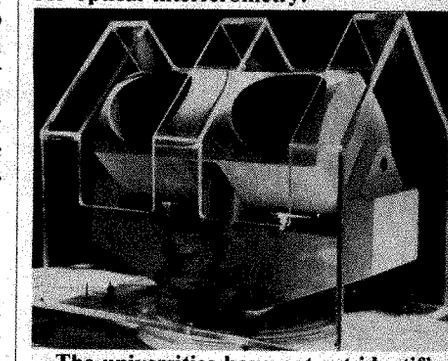
Alternatives neglected

Washington

A STUDY of animal experimentation by the National Academy of Sciences* suggests that institutional barriers within the biomedical community in general and the National Institutes of Health (NIH) in particular may discourage researchers from developing models of human disease and physiology based on non-mammalian organisms. The study, which was commissioned by NIH, does not directly criticize NIH's funding patterns; it does, however, recommend that the agency should support good research "without taxonomic or phylogenetic bias" and consider directing funds specifically to the development of promising model systems. Harold Morowitz of Yale University, chairman of the study, said there is "anecdotal evidence that it is difficult for people working on unconventional models to get funding". The natural bias has been in favour of using organisms closest to man, he said; unconventional proposals submitted to NIH for support do not usually fit into the mandate of any of the standard study sections, and are reviewed by *ad hoc* committees that are not always sympathetic.

Morowitz said that researchers working in unconventional systems often report that they managed to get started only by "bootlegging" funds from other more conventional research projects.

The study notes that as biological understanding shifts more and more to the molecular level, increasingly the best model for human disease and physiology is not a closely related whole organism that displays a similar macroscopic feature; rather it is often many organisms, each an analogue of a fundamental biological principle involved. One example cited in the study is research on the human disease myasthenia gravis, a neuromuscular disorder. Six different animal models have been used to discover its cause: an autoimmune attack on acetylcholine receptors at neuromuscular junctions. Studies on chick muscle cells in culture showed that a snake venom binds specifically to these receptors; the venom was then used to demonstrate that patients had a striking shortage of receptors. A cobra neurotoxin that blocks the receptors was administered to rats to see if a shortage of receptors could explain the observed disease symptoms. And to see if an autoimmune response could be involved, rabbits were immunized wth receptor cells isolated from invertebrate species.



Stephen Budiansky

**Models for Biomedical Research*, National Academy Press, Washington, DC, 1985 $18.50.

Big telescope race

Washington

OHIO State University and the University of Arizona have decided to raise a total of $25–30 million for an 8-metre monolithic mirror instrument to be built on Mount Graham in southeastern Arizona. If others can be persuaded to join the project, the telescope may even be equipped with two 8-metre mirrors, which could be combined for optical interferometry.

The universities have not yet identified the private sponsors who they hope will supply most of the capital cost of the instrument. Both universities have, however, recently launched large fund-raising efforts, with a target of $100 million at Arizona and $250 million at Ohio. Astronomers at both universities are confident that the money will be found.

The telescope, which would also operate at infrared wavelengths, will have computer links allowing it to be operated remotely from both Arizona and Ohio. The miror or mirrors will be made using a technique developed by Roger Angel at Arizona (see *Nature* 295, 651; 1982) in which mirrors of honeycomb structure are spun-cast into a parabolic shape. A new computer-actuated lap allows very deep dishes to be polished with a focal ratio of *f*1, so that telescopes can be built that are much smaller and cheaper than hitherto. A 1.8-metre mirror made recently using the new technique "came out beautifully", according to Dr Angel. Preliminary design work on the new telescope is due to start later this year; construction might take a further four years.

Tim Beardsley

Changing the objectives

SIR — Your leading article of 7 March (p.1) deals with policies for UK science, including astronomy, in the context of fixed or declining resources. You say: ". . . one, or the other, or perhaps both of the observatories must go . . .". You suggest that the "good work these laboratories do . . . could be transferred intact to universities". Another problem is that experimental facilities have become "institutionalized".

I suggest that a contract-based laboratory might be set up in the general subject area of physical technology, of which astronomical technology would be part. It would absorb some staff and property of the Royal Greenwich Observatory and the Royal Observatory, Edinburgh. It should probably not absorb the Nautical Almanac Office and historical collections of the observatories, which need limited resources and could continue independently.

This suggestion is intended to be more far-reaching than simply merging the observatories. The organization is not going to be a literal observatory because the relevant instruments are overseas. It is more of a research and development organization, a design office and a workshop. Although such a new laboratory would start by working on instruments for astronomy, that need be only one of its jobs. There seems little to be gained from total specialization. The aim would be to add versatility and university contacts and to give the establishment responsibility for its own fate. Versatility in the face of change is relevant to present circumstances. There could be many other gains. Developments in one area of technology such as astronomical instrumentation need inputs from other subjects and in turn ought to be generally disseminated — that process would also be helped. A vigorous working environment is foreseeable.

The question must be asked: would such a laboratory take money or talent needed elsewhere? The answer must lie in the way it is run. Its income would not be unfair if it was gained by offering a service that could be refused. Such operations would be based on contracts.

For a new laboratory, the foundation itself could take the form of a contract or agreement between the Department of Education and Science and the management authority, which could be a university. A notable example is the vast Jet Propulsion Laboratory in Pasadena, which is managed by the California Institute of Technology on a contract. To maintain the service principle, the foundation agreement itself should not provide much of the running expenses for technology. The foundation could reasonably support some scientists. The research councils should probably not be legally involved in the foundation as the laboratory would be one of their contractors.

It should be appreciated that the observatories' research astronomers are few in number and their continued support is not a problem that can relevantly be compared with that of providing and operating the larger research facilities which are basically for universities. The practice of astronomy has been the attractive feature of the observatories for many staff who have eventually worked in technology. The total contribution of the observatories' astronomers to the provision of facilities, as well as to the provision of fundamental data and to research programmes, is such that they can surely be included in the framework proposed. Some posts would be part of the foundation agreement, some would be Science and Engineering Research Council (SERC) fellowships applied for in the usual way, some posts including direct responsibility for instrumentation would be supported by contracts. It would be open to the organization to use any net income to employ extra scientists.

Such a laboratory would be clearly distinguishable from others. The differences would be in the combination of the university connection, contract operation, flexibility in the type of work, the laboratory and the university together seeking work and the origins in astronomical technology (mainly optics, detectors, computing and mechanical engineering).

The operation of existing research facilities and building of new ones would be on the basis of a number of separate long or short-term contracts. Scientists requiring such work would probably act through SERC, using either a grant or a direct contract from the council for common facilities. Ultimately, these contracts could be placed or not as required and could be refused by the laboratory: cancellation would be regulated by the contract.

The laboratory would therefore have the need and the opportunity to support itself (as distinct from subsidizing the facilities). This it would do by seeking government and commercial work which should not be circumscribed. The laboratory could sell its services, software and the rights to its inventions.

From the scientists' point of view, much would depend on the continuing goodwill of the managing university. Success would depend on the local management and staff, and sanctions would be available through the contracts.

Plight of refusniks

SIR — Ten years ago, on 12 March 1975, my family applied for exit visas from the Soviet Union for the first time. I was immediately removed from my position in the mathemetical department of the Institute for Chemical Physics of the Academy of Sciences of the USSR. At the same time, a total boycott was organized against my family in the scientific centre of the academy in Chernogolovka.

For ten years I have been prohibited from attending seminars, conferences and symposia. Correspondence from abroad is not delivered to me. I do not receive scientific journals, including those of the American Physical Society and the American Mathematical Society. The Academy of Sciences presses my foreign colleagues to abandon attempts to meet me and then to take part in the scientific boycott against me.

For ten years we have been stubbornly making efforts to get exit visas. In 1979, representatives of the academy, academician N. Emanuel, Academician N. Semenov and others, officially stated that the academy had no objections to my departure, and we were informed that the Soviet leaders had made an official decision to give our family exit visas. But this decision has not been implemented.

My numerous meetings with the general secretary of the academy, Academician G. Scrjabin, showed that the academy blocked the fulfilment of this decision.

The situation has abruptly become worse after negotiations between the Academy of Sciences of the USSR and the National Academy of Sciences of the United States. Academician Scrjabin and Academician Yu. Ovchinnikov, a vice president of the academy, immediately refused to discuss my problem with me. And Academician E. Velikhov, another vice president of the academy, refused even to speak with me.

SOLOMON AL'BER
Moscow, Soviet Union.

Abstract policy

SIR — In regard to the previous correspondence on the abstract policy of the Biosciences Information Service (BIOSIS) (H. E. Kennedy, *Nature* **310**, 96; 1984), I would agree with those favouring their inclusion. I would point out, however, that the only thing worse than no abstract is a reference to one when there is no obvious way of obtaining a copy. BIOSIS apparently does not intend to offer OATS (original article tear-sheet service) as does the Chemical Abtracts Service.

Would it be too much to ask that some record be provided as to which libraries hold these abstract volumes in a manner similar to CASSI (Chemical Abstracts Service Source Index) or that they be deposited in the British Library Lending Division or a library which reports its holdings to the Online Computer Library Center?

Industrial collaboration on show

Professional people do not spend time as salesmen at trade fairs each year. But there is much to be learned from what went on at Hannover last week.

Hannover

ALMOST as a matter of principle of general applicability, most people agree that it is wrong to throw out the baby with the bathwater, an image that no doubt derives from the time when baths were movable and plumbing for carrying away waste water had not been developed. The difficulty in most interesting cases is to know which is which. That may be one of the reasons why British universities have for so long felt so threatened by the British government's mixture of exhortation and incentive intended to make them contribute more directly to national prosperity. More applied research means less fundamental research, as in any zero-sum game. The huge annual trade fair that ended here last week provided ample illustrations that this calculation is far too simple.

One of the most unexpected features of this trade fair is that universities take their place alongside industrial companies as exhibitors, sometimes under their own steam, sometimes under the wing of the governments that support them, the *Länder* in West Germany. This year, one of the most important shows of this kind was that provided by the universities of North-Rhine Westphalia, the regional government whose policy on higher education was the most expansionist of all when the whole of higher education in West Germany was growing rapidly fifteen or twenty years ago. Lower Saxony, the local *Land*, was also represented, as was Berlin, universities such as Heidelberg as well as a host of publicly supported laboratories whose work is, in part at least, academic in character. At a guess, there would have been more than 200 people with academic positions or pretensions manning stands at all times during the eight days of the fair.

Why were they there? There is no secret. As with the strictly commercial exhibitors, money is the objective, either an agreement with an industrial company for the commercial development of a device or such a powerful expression of industrial interest that further funds for a research project can be had from one of the public sources of research support, the *Deutsche Forschungsgemeinschaft* (an all-embracing research council), the ministry of research and technology (BMFT) or, more often than one would guess, some other ministry.

The ingenuity and diversity of what these academic people have had to show has been compelling, which is attested by the way in which the university exhibits have generally been occupied with visitors engaged on deep discussions. (Quite often there is also a certain amount of socializing, as when people from industry try to discover what their ex-teachers are doing now.) Machines and devices predominate, computer programs and applications come next, but there is also a cement of biological research, and of electronics applied to medicine, to give the show coherence.

Diversity is also represented by the variety of institutions with things to show. Some of the great universities are there, but so too are the technical colleges of West Germany (*Fachhochschülen*) and the more recent and controversial creations, the comprehensive universities of the 1960s (*Gesamthochschülen*). In interest and ingenuity, there has been little to distinguish between them. One feature of this unusual academic show is that the chief salesman (and inventor) has been a full-throated enthusiast for what he has to show who can be diverted only with difficulty into talking about more general questions, how his university is faring, or how he balances research and/or development with teaching. (The personal pronoun "he" seems generally applicable.)

The question where the idea came from in the first place seems to yield a great variety of answers. One academic inventor says he had returned from a previous Hannover fair astonished that the great engineering companies had not thought of a way of solving a simple technical problem. Many say their work has its roots in the immediate needs of a local hospital or industrial company.

Showing off the product is not exhibitionism, but an attempt to put the development concerned on a sounder footing. The academic exhibitors also agree that success will bring them kudos back home, perhaps inversely to the standing of their institution. Although the exhibitors are necessarily a self-selected group, they make it seem entirely natural that showing a device should be a part of normal academic life.

Like the academically inclined researchers from the West German national laboratories, they no doubt sense pressure from above to be doing something useful. Indeed, for the national laboratories, technology transfer has been this year's theme for the fair. Inevitably, many of their projects are on the grander scale. The surprise is that many of them are just as particular. Techniques for bonding metal and ceramic may as well be used in useful domestic gadgets as, for example, in thermonuclear machines. But for the people from the national laboratories, where government edict may matter more directly, there is less enthusiasm for the incidental applications than for the real purpose.

The texture of the exhibition of research is the biggest surprise. It is natural that inventors should be enthusiasts with, occasionally, an air of zealotry. Predictably, the things on show range from particular devices to generally applicable techniques. The theme that holds them all together is the belief that there may be profit in what they have to show.

Everybody acknowledges that this is just a chance, but they are keen to be on show as if that were sufficient in itself; at least they will be able to compare their work with that of others, or learn something useful from their visitors.

The morals in this experience for academic communities other than West Germany are obvious and widely understood. Indeed, in places such as Britain, everybody pays lip-service to them. First, there is no necessary contradiction between membership of an academic faculty and a research interest which is better called development.

Second, there is no way in which the professional people manning these stands can be distinguished from those encountered at quite different gatherings, conferences for example; perhaps this is something distinctive about West Germany, but the machine builders seemed refreshingly interested in what, say, the particle accelerator people are up to. (To university administrators, in any case, the only achievement that counts is success.) Third, even in publicly supported systems of higher education (and the West German system institutionalizes government support for universities to a degree no longer allowed in Britain), extra funds without strings attached are translated into ordinary currency at a higher rate.

That industrial collaboration can be rewarding and respectable is understood elsewhere in Western Europe and North America. (Japan is different; universities deal privately with industry at the outset and exhibit only their successes at even grander fairs.) But while understood, there is a sense in which it is not believed. Academics who dispute that will be more convincing when they put themselves on show, at Hannover or elsewhere.

John Maddox

Population biology

Evolution of pesticide resistance

from Robert M. May

ALL natural populations contain genetic variability. The selective forces resulting from continued application of pesticides (or herbicides or antibiotics) will therefore lead to the target population eventually becoming resistant. There are now several examples of evolution at work in this way that have been studied in at least as much detail as industrial melanism in the peppered moth, the standard example of microevolution in elementary biology texts. Over 400 species of agricultural pests are now resistant to one or more pesticides, and this erosion of the early successes of chemical pesticides is reflected in the fact that in the 1940s around 7 per cent of all US agricultural crops were lost to insects, whereas the corresponding figure is now 13 per cent. Although the ultimate appearance of population-level resistance is usually inevitable, a variety of measures may be adopted to retard its appearance in particular cases.

For an enormous range of different pesticides and target organisms, the number of generations taken for a significant degree of resistance to appear exhibits a surprisingly small range of variation, typically being around 5-50 generations, despite great variation in the underlying genetic mechanisms and in the intensity and frequency of pesticide application. Conventional population genetics can shed light on this observation. Suppose, to begin with, that resistance involves only one locus with two alleles: *SS* genotypes are susceptible to the pesticide, *RR* genotypes are resistant, and *RS* heterozygotes have some intermediate degree of resistance (that is, $w_{RR} > w_{RS} > w_{SS}$, where w_{ij} is the fitness of the genotype ij in the presence of the pesticide; if R is completely recessive, $w_{RS} = w_{SS}$; if R is completely dominant, $w_{RS} = w_{RR}$). The resistance allele R will usually be at very low frequency (p_o) in the pristine population, and under pesticide application its frequency will at first tend to increase in the ratio w_{RS}/w_{SS} from generation to generation[1]. The number of generations, n, that elapse before the R gene attains a frequency sufficiently large to produce noticeable resistance in the population as a whole (p_f) may thus be estimated by compounding this fitness ratio until $(w_{RS}/w_{SS})^n \sim (p_f/p_o)$.

From this very crude approximation, we can see that the number of generations required for the population to evolve resistance depends only logarithmically on fitness ratios and on p_o. In other words, the characteristic time to evolve resistance indeed depends on such quantities as p_o (estimates of which range from 10^{-2} to 10^{-13} in various circumstances according to R.T. Roush of Mississippi State University), the degree of dominance of the R allele (usually intermediate between the extremes of recessive and dominant), the strength of selection (which ranges over several orders of magnitude, depending on the management of the particular pest/pesticide system), and other factors. When logarithms are taken, however, these enormous ranges collapse to a factor of around ten separating the further extremes, making the roughly 5-50 - generation 'rule' a good deal less surprising.

Discussion at a recent symposium* revolved around the interesting details and exceptions that make the preceding crude generalizations inapplicable to specific cases. For example, is an insect pest that has evolved resistance to one pesticide likely to be faster in evolving resistance to another pesticide? May mixtures of pesticides work better than the same pesticides used in sequence? Better understanding of the molecular biology underlying the genetics of resistance can help here. Faster resistance to new pesticides is clearly likely if they are chemically similar to old ones. Less obviously, as emphasized by M. Whitten (CSIRO, Canberra) and others, the first pesticide could promote selection for mutator genes, thus speeding the evolution of subsequent resistance even to chemically dissimilar pesticides.

Although much of the discussion centred around the molecular biology of resistance, more attention to the population biology of resistance is also needed. G.P. Georghiou (University of California, Riverside), Roush and others emphasized that migration from untreated to treated regions by susceptible individuals represents flow of susceptible genes that works against selection for resistance. This invokes echoes of the grander theme of whether geographical isolation is necessary for speciation[2,3]; that is, under what circumstances will gene flow (migration) wash out the selective forces (pesticide application) that are tending to adapt an organism to its local environment (evolving resistance)? H.N. Comins and others have shown that the answers depend both on the magnitude of migration in relation to the strength of selection, and on the type of density dependence exhibited by the pest population[4-7].

In deliberately oversimplified terms, a population is said to exhibit 'perfect' density dependence if, following any disturbance, the population tends to return to some constant value in the next generation. In contrast, if an 'overcompensating' population is perturbed below its long-term average value in one generation (for example, by pesticide application), it will tend to bounce back above this value in the next generation. A population with 'undercompensating' density dependence will tend to recover steadily and monotically following disturbance; if depressed to low values by pesticide application in one generation, such populations will tend still to be lower than usual in the next generation. When these considerations of population dynamics are added to selection and gene flow, it is concluded that — other things being equal — pest populations with overcompensating density dependence will tend to evolve pesticide resistance faster than ones with 'perfect' density dependence, because the migration of susceptible genes into the overcompensated population that follows pesticide application has less effect than would be the case under 'perfect' density dependence[4]. Conversely, if the pest population exhibits undercompensating density dependence, the resistance-slowing effects of migration from untreated regions will be relatively more significant[4].

In practice, the weather and other environmental factors often superimpose density-independent fluctuations that mask the density-dependent effects, at least in the short run; for this and other reasons, analyses that characterize the degree of overcompensation or undercompensation of particular insect populations are more easily carried out for laboratory than for field populations. However, whereas most field populations for which good data are available appear to exhibit undercompensating density dependence (among the exceptions, the most pronounced is the Colorado potato beetle, which is notorious for the speed with which it has developed resistance to a wide range of pesticides), the majority of laboratory populations show marked overcompensation[8-10]. The difference, which probably derives from the many natural mortality factors that are seldom present in the laboratory, underlines the need for caution in extrapolating laboratory studies of the evolution of resistance into a field setting.

The propensity for pest species to evolve resistance more quickly than do their natural enemies has often been remarked, and creates obvious problems. Building on earlier work by Croft and others[11,12], B.E. Tabashnik (University of Hawaii) surveyed two possible explanations. The first is that the co-evolution between plants and phytophagous insects has preadapted the insects to the rapid evolution of detoxifying mechanisms, whereas their natural enemies have had less opportunity to preadapt. But laboratory studies show that there are no simple general patterns of this kind and that under controlled conditions the rate of evolution of resistance in prey and predator populations depends on the detailed molecular mechanisms underlying detoxification[13,14]. This, in turn, has prompted a search for pesticides that may be less lethal for natural enemies than for

*National Academy of Sciences/National Research Council International Symposium on Pesticide Resistance Management, 27-29 November 1984, Washington D.C.

pests[15-17], or even for the release of natural enemies that have been artificially selected for resistance to specific pesticides[18].

The second possible explanation lies in the dynamics of prey/predator associations. The essentials of Tabashnik's detailed numerical simulations[11] can be appreciated from the qualitative arguments given above. Suppose application of a pesticide kills a large fraction of both prey and predators in the treated region: for the surviving prey, life is now relatively good (relatively free from predators), and the population is likely to increase rapidly — exhibiting overcompensating density dependence; for the surviving predators, life is relatively bad (food is harder to find), and their population will tend to recover slowly — exhibiting undercompensating density dependence. But we have just seen how the interplay between selection and gene flow is such that overcompensation tends to speed the evolution of resistance, and undercompensation to retard it. Thus, on dynamical grounds alone, we may expect that pests evolve resistance faster than do their natural enemies.

Although many well-understood resistance systems involve one locus with two alleles, with heterozygotes of intermediate fitness, other systems are possible and can pose different kinds of management questions. For instance, *RS* heterozygotes may be the most fit in the presence of the pesticide. Resistance of the Norway rat to warfarin is the clearest example, and anyone who is tired of presenting sickle-cell anaemia to classes as the canonical example of heterzygous advantage may care to note the fitness ratios of the Norway rat in Britain in the absence of warfarin are $w_{RR} : w_{RS} : w_{SS} = 0.46 : 0.77 : 1.00$, whereas in the presence of the poison they are 0.37 : 1.00 : 0.68 (J. Greaves, MAFF, South Tolworth, Surrey). But there may also be examples of heterozygous superiority among insects, as in the resistance of the spotted root-maggot *Euxesta notada* to DDT or dieldrin[19]. Heterozygous superiority of this kind undercuts the simple analyses presented above[20].

Resistance systems that are sufficiently polygenic to warrant treatment by quantitative genetics, rather than being inherited in discrete, diallelic fashion, present interesting possibilities (S. Via, University of Iowa). For example, resistance to two different pesticides can be negatively correlated, enabling the evolution of resistance to be retarded by alternating the pesticides. Conversely, if the correlation were to be positive it would result in swift appearance of resistance to the second pesticide, following sustained use of the first. M. Uyenoyama (Duke University) discussed possible complications arising from modifier genes in two-locus systems of resistance. One possibility is the removal of fitness disadvantages in resistant genotypes in the absence of pesticide usage, if ever the resistance gene attained high frequency; if this happened, one could not rely on 'back-selection' to purge resistance genes from the population after application of the pesticide was discontinued.

If dosage levels, migration, refugia, natural enemies and other factors are to be managed so as to slow down the evolution of pesticide resistance, coordination of efforts over large regions will be required. Some crops lend themselves to this, and some do not. Often the best interests of individuals will differ from those of groups, leading to problems that are social and political rather than purely biological. Beyond this, even with good biological understanding and coherent planning of group actions, I think it will often be that different sectors — pesticide manufacturers, farmers, and the planners responsible for feeding people — have different aims, stemming from different rates of discounting the future and the absence of a truly common coinage. Population biology can make these tensions clearer, but it cannot resolve them. □

Most ancient aggregation of serpents

THE oldest record of serpent aggregation is preserved in this rare fossil from the Oligocene White River Formation of Converse County, Wyoming. The assemblage consists of three virtually complete 32 million-year-old snakes passively coiled in life-like positions. As described by Brent H. Breithaupt and David Duvall of the University of Wyoming, USA (in a paper in the press in *Rates of Behavioral Evolution*, ed. Bocout, A.J., Plenum, New York; and in a manuscript under review) the largest snake (435 mm long) belongs to the genus *Ogmophis*, whereas the smaller pair belong to the genus *Calamagras*. Both genera are common middle Tertiary forms of the subfamily Erycinae, family Boidea, and are distantly related to the North American rubber boa (*Charina*) and rosey boa (*Lichanura*). This specimen represents the most complete material known for these two fossil genera and is the first serpent cranial material recovered from Oligocene strata of North America. It is also the only known specimen in the world in which more than one complete snake is preserved and it suggests that aggregation, a behaviour that is extremely common in living snakes, was already a feature of serpent social behaviour at least 32 million years ago.

Growth factors

Neuropeptides as mitogens

from Michael R. Hanley

THE current enthusiasm for the study of proliferative growth factors is mostly based on the conviction that they are mitogens, endogenous regulators of cell division. A favourite model for mitogenic signalling is experimentally induced cell division, where both quiescent and normally dividing cell populations are stimulated to divide rapidly and replace damaged tissue. The stimuli for tissue repair are unknown but most speculation has focused on tissue-derived or blood-born mitogens such as platelet-derived growth factor. On page 61 of this issue, however, Nilsson *et al.* report that two related neuropeptides contained in sensory neurones, substance P and substance K, can act as mitogens for connective tissue[1]. This discovery is particularly significant because both peptides may also participate in other aspects of the reaction to injury: sensory signalling and neurogenic inflammation[2]. The discovery has important implications for other peptides found in peripheral nerves and also suggests that neural factors have a previously unsuspected role in the coordination of cell proliferation.

The authors use the standard strategy for identifying potential mitogens; the target cells are isolated in primary culture and the onset of cell division monitored autoradiographically by measuring the incorporation of ^{3}H-thymidine into nuclei after stimulation with the potential mitogen. This permits quantification of responses in a morphologically defined cell population and provides a selective measure of a rapid initial event in mitosis, entry into DNA synthesis. In two connective tissue populations, skin fibroblasts and vascular smooth muscle cells, Nilsson *et al.* show a potent, dose-dependent stimulation of DNA synthesis in the presence of the tachykinin neuropeptides substance P or substance K, but not to another neuropeptide, bombesin.

The actions of substance P and substance K seem to be mediated by an authentic tachykinin receptor because their effects are reduced by a specific tachykinin antagonist. Recently, the existence of multiple tachykinin receptors, which may respond to different endogenous peptides, has been suggested[3]. Substance K has a greater potency then substance P, suggesting that a specific subtype of tachykinin receptor[3] is involved in the mitogenic responses, which poses the interesting possibility that the mitogenic effects of tachykinins may be associated uniquely with this class of receptors, and that other cell populations bearing these receptors may also have proliferative responses to tachykinins.

The work of Nilsson *et al.*[1] is the latest contribution to the accumulating evidence that neuropeptides can act as mitogens. For some time, Rozengurt and his colleagues have explored interactions between mitogenic signals in a cell-line model of quiescent cells, serum-starved 3T3 cells. In this system, they have correlated mitogenic activity with the peptides vasopressin[4] and bombesin[5]. Unlike substance P and substance K, however, these peptides have a complicated, possibly synergistic, interaction with other mitogens in 3T3 cells. This difference reflects fundamental differences in the responses of a growth-arrested permanent cell line and a normally quiescent primary culture cell. Nevertheless, the 3T3 model provides a simple prediction that vasopressin and bombesin may be mitogenic for normal cells. Vasopressin has been reported to stimulate DNA synthesis in chondrocytes[6] and bone marrow cells[7]; bombesin, or its mammalian relative gastrin-releasing peptide, can be a growth factor for bronchial epithelial cells[8]. As with the tachykinins, the possibility that these peptides may be endogenous mitogens gains added interest because related peptides occur in mammalian peripheral nerves[9,10], providing ideal local sources.

The tachykinin-stimulated DNA synthesis is neither additive nor synergistic with that elicited by platelet-derived growth factor. In other systems, this observation has been taken as evidence that a common effector mechanism is involved, but it is pertinent to consider whether this explanation is plausible. Elsewhere, the inositol phospholipid pathway, recently delineated in some detail, has been proposed as a common route in the actions of all mitogens[11]. Significantly, the tachykinins, vasopressin and bombesin all stimulate the inositol phospholipid pathway and mobilize cellular calcium, possibly as a direct result of producing the second messenger inositol 1,4,5-trisphosphate, which releases calcium from a non-mitochondrial intracellular pool[11]. Consequently, any receptor acting on the inositol phospholipid pathway may ultimately stimulate cell division. Whether this is a useful generalization for peptides awaits a detailed evaluation of the inositol phospholipid-regulating peptides for their mitogenic activity on target cells. If, as already seems likely, only a subset of such peptide receptors has mitogenic effects, it will be a major challenge to identify any unique aspects of the biochemistry of lipids and second messengers that may correlate with the stimulation of DNA synthesis.

The next logical step will be to evaluate the mitogenic potential of the tachykinins *in vivo*. There are already some preliminary pieces of evidence that strongly support the idea that sensory neurones containing these peptides participate in both normal and stimulated cell growth. A single neonatal dose of capsaicin, the pungent agent of capsicum peppers, permanently destroys a population of sensory neurones that are involved with pain perception and nerve-mediated inflammation[12]. Although this population is chemically heterogeneous, it includes the tachykinin-containing neurones, so neonatal capsaicin treatment provides a method of deleting the cellular influence of tachykinin neurones. Intriguingly, lesions in skin[12] and corneal epithelium[13] frequently result from this treatment. The mechanism of the lesion formation has not been examined in detail but morphological studies suggest that in the cornea the proliferating basal layer of epithelial cells and the normal geometry of cell renewal are severely impaired[12]. Clearly, a specific role for the tachykinins cannot be inferred, but this evidence suggests that a factor from sensory neurones is essential for normal cell turnover in the cornea and, possibly, in the skin.

If corneal damage were to result from the loss of a mitogenic peptide input, could there be a corresponding disorder arising from the local overproduction of a mitogenic peptide? Although skin keratinocytes have not been shown to be targets for tachykinins, there is a large density of tachykinin nerves, presumably of sensory origin, in the basal layers of the epidermis[14], which contains actively mitotic cells that divide to replace the outer layers of skin. Local factors are presumed to regulate keratinocyte proliferation, but little is known about such factors. Psoriasis is a skin disorder in which normal control is lost and the cells proliferate at a greatly increased rate. An expanation for the condition may be that the sensory tachykinins exert a tonic control over normal basal layer cell division, and that, in psoriasis, there is an excessive mitogenic stimulation of keratinocytes. This hypothesis could be conveniently evaluated by the topical use of tachykinin antagonists.

100 Years Ago

REPORTS from Japan state that grave fears were entertained of an outbreak of the long quiescent volcano Fujiyama, and that officials had been sent to investigate the matter. The people living in the neighbourhood believed an eruption to be imminent, because, while the snow on the mountain had begun to melt two months before the usual time, all the wells at the fort became dry, and difficulty was experienced in procuring water. The phenomenon is considered the more remarkable from the fact that the winter has been unusually cold, and that the surface of the snow remains hard, the part nearest the ground being the first to give way. Intelligence has also been received from Java of the eruption of the Semiroo mountain, the most active Javanese volcano.
From *Nature* **31** 610, 30 April 1885.

Strictly, the conclusions of Nilsson *et al.* apply only to peptides found in sensory neurones. However, the results with bombesin and vasopressin[4,5], which have not so far been found in sensory neurones, strongly suggest that other parts of the peripheral nervous system may also exert proliferative influences on normal, stimulated or developing cell populations. One intriguing consequence of these investigations may be to reveal for the first time a defined cellular origin for an identified substance with mitogenic action. □

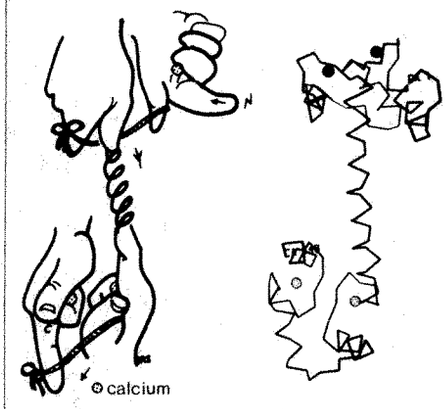
Protein structure

Hands on the calcium switch



from C. Schutt

THERE is no such thing as a boring protein; newly solved protein structures always contain surprises. Yet the calmodulin structure published on page 37 of this issue[1], and the closely similar troponin-C molecule[2,3], turn out to be even more interesting than usual. The simple 'dumbbell'-shaped molecules, with their easily grasped polypeptide fold, invite close scrutiny of the fundamental mechanism of molecular switching.

These proteins sense intracellular calcium signals and trigger, through changes in conformation, appropriate responses in associated proteins. Calmodulin is a ubiquitious, highly conserved, eukaryotic protein implicated in many coordinated, calcium-dependent cellular responses[4], whereas troponin-C is part of a protein complex bound to actin filaments in vertebrate muscle that 'switches on' contraction when calcium is released from the sarcoplasmic reticulum[5].

The three-dimensional organization of calmodulin is easy to visualize: knobs at both ends of a long exposed helix, with each knob having paired, back-to-back, calcium-binding subdomains (EF-hands) of the type first described for parvalbumin[6]. An EF-hand is a structural motif (see figure) with a 12-residue calcium-binding loop, pictured as the middle finger of the right hand, flanked by two nearly perpendicular helices, represented by thumb and forefinger. In the crystal structure, the concluding helix of the second calcium-binding subdomain runs without interruption into the starting helix of the third binding subdomain, forming the long central helix. It is the splendid isolation of this helix that is unexpected — the tertiary fold of the knobs had been predicted.

In a pioneering use of sequence homology to predict protein structure, troponin-C was determined to have four calcium-binding subdomains[7-9]. Using the criterion of compactness and structural homology with the parvalbumin molecule, Kretsinger and Barry produced a pleasing model of troponin-C with four EF-hands symmetrically packed around a hydrophobic core[10]. This model has recently been challenged by Tsalkova and Privalov[11], who argue from thermal denaturation results that the protein melts as if comprising three independently folded 'cooperative units'. They conclude that the middle part of the sequence, now

known to form the central helix, somehow prevents the other two units from interacting — a remarkable prediction in view of the three-dimensional structures just published. It is also known that limited proteolysis can split these molecules into two intact but non-associating calcium-binding domains[12]. Would this information have helped to get the prediction right? Perhaps such zero-dimensional experiments will become a more important component in future attempts to predict protein structure from sequence homology.

How might the binding of calcium to such a structure act as a conformational switch? In the case of troponin-C, two of the calcium-binding loops (in the amino-terminal lobe) lack calcium in the crystal and, significantly, have altered inter-helix angles from the standard EF-hand, the thumb and forefinger being nearly parallel. These differences are large enough to be recognized by other proteins, especially if there is a relative rotation of the two lobes about the axis of the central helix. A more radical (but not unreasonable) suggestion by Herzberg and James[2] is that a glycine residue in the middle of the long central helix serves as a pivot about which the two halves of the dumbbell can freely rotate, perhaps even coming into contact. Such a dramatic change could certainly serve as a switch, possibly initiated by ligand-induced changes in the calcium-binding subdomain at the amino-terminus of the helix.

The question, then, is whether the secret of this molecular switch lies with the instability of the long bridging helix? Proteolytic cleavage studies show that this region does have an altered conformation in the absence of calcium. Furthermore, thermal denaturation studies[11] identify the helix as the least stable part of the structure. Perhaps an exposed helix — a rare feature in protein structures — tottering on the edge of conformational stability has exactly the required sensitivity to respond to energies produced by calcium binding. One is reminded of glucagon, a small protein of borderline stability in solution, which only reveals its helical conformation in the crystalline state[13]. Such a delicate balance between order and disorder could be the basis of switching in all these molecules.

It is tempting to carry these speculations too far. Calmodulin and troponin-C are only functional while interacting with other proteins and the central helix could well be buried in these situations, or more subtle aspects of protein-protein recognition might predominate. Nevertheless, particularly by the use of genetically engineered mutants, these proteins may yield deep insights into the relationship between the signalling and stability properties of proteins. Finally, we might ask why such a simple structure was not anticipated, when most of its subdomains had been correctly predicted? My guess is that someone, somewhere, did get it right — but who would want to go down as the first to predict a dumbbell when, if the prediction was wrong, their name might so easily become attached to it? □

Acidification and decline of Central European forests

from Nico van Breemen

WHAT is probably the most complete set of data available on the effects of atmospheric sulphur and nitrogen on the weathering of soil and rock, and on the composition of drainage water in forested and agricultural areas, is reported on page 31 of this issue by Thomas Paces[1]. Of particular interest is that one of the areas (all of which are in Czechoslavakia) is characterized by extremely high sulphur inputs and a complete dieback of spruce forest, a situation that may be typical of several industrial regions in eastern Europe. Paces concludes that the forest in the industrial region is strongly acidified. But is acidification responsible for the dieback?

Dry deposition of sulphur dioxide is responsible for 75 per cent of the acidification in the industrial region whereas wet deposition (acid rain in the strict sense) contributes only 15 per cent to the total acid load of the system studied. In relatively remote forests, the acid load is only about a third of that in the industrial region, and the contributions of wet and dry deposition to the total acid load are about equal. Soil acidification is considerable in such areas but the drainage water is almost neutral. Agricultural activities (fertilizer application and harvesting) contribute considerably to the acid load of soil and rock, resulting in increased mineral weathering.

Changes in the chemical composition of water of the Elbe river over the past 80 years indicate that these conclusions, although based on data drawn from four small representative watersheds, are valid for large areas. All the four have similar bedrocks, soils and climates but differ in their exposure to atmospheric pollution and land use. Paces combines detailed hydrological measurements and estimates of chemical input and output (including records of fertilization and harvesting) over five to seven hydrological years with a recently developed steady-state model of weathering, to quantify acid production and consumption by known geochemical and biological processes. Inputs of sulphur and nitrogen by dry deposition were estimated from measured concentrations and published values of deposition velocities.

Although some authors still contest that atmospheric deposition of anthropogenic sulphur and nitrogen seriously contribute to acidification of soils[2,3], Paces's data are in agreement with several independent lines of evidence for increased environmental acidification as a result of atmospheric deposition. The first direct evidence for the strong soil acidification in Central Europe of the past decades came from *p*H measurements of old and new soil samples by Butzke[4]. At a workshop at Uppsala last September, C.O. Tamm from the University of Uppsala reported a small drop in the *p*H of forest soils over the past 50 years in northern Sweden but a much larger acidification in the southern part of the country. Tamm attributes the small *p*H decrease in the north mainly to biological processes and the large decrease in the south to atmospheric inputs. Other input-output budgets[5], geochemical studies of soil weathering profiles[6] and simulation models of soil acidification[7] also lead to the same inescapable conclusion: the rate of acidification of forest soils in a large part of Europe (and north-eastern America) is greatly accelerated by atmospheric pollution. Although this acidification has markedly depressed the *p*H of sensitive forest soils in Central Europe, forest soils in the United States and Canada seem still to be able to buffer the *p*H in a range that can be considered normal.

Although there is general agreement that the acidification of lakes and streams is detrimental to fish and other biota[8], the relation between soil acidification and the widespread decline in forests of Central Europe is still controversial; the link between the acidification of soil and death of spruce forests indicated by Paces is not proven. Usually, direct effects of atmospheric gases, including photo-oxidants, may be more important than soil acidification in damaging trees. Nevertheless, the removal of base cations and release of potentially toxic aluminum by acidification must be detrimental to trees and other forest plants. In the long run, soil acidification may be a bigger problem than the direct effects of gases on vegetation: although a reduction in pollutant emission would have an almost instantaneous effect on air quality, recovery of acidified soils is presumably very slow and is only possible if sufficient quantities of weatherable silicate minerals are still present.

In that respect, the acidification of agricultural soils (also demonstrated by Paces) is a minor problem. The acidifying effects of harvesting and fertilizer application are normally counteracted by liming. Additional effects of atmospheric acids can easily be undone in the same way.

Liming, however, probably offers no practical solution for forests. Apart from the fact that acid deposition rates are higher in forests than on land[9] and the problem of how lime could be applied in forest areas, forest liming could result in undesirable side effects from increased decomposition of organic matter, nutrient imbalances, increased susceptibility to pests and diseases and changes in the species composition of the ground vegetation. Both the direct effects of atmospheric pollution and the long-term problems associated with acidification of the environment can only be solved by a reduction in the emissions of gaseous sulphur, nitrogen and hydrocarbons. □

Primate cognition

Can apes learn to count?

from Brendan McGonigle

DANZIGER once described mathematics as the language of size, natural language as the language of sort. Are these languages confined to the human brain? Although research (and controversy) continues on whether apes share important features of our natural language system, attention is now turning to the question of whether they might also possess the rudiments of a number system. Thus, on page 57 of this issue, Tetsuro Matsuzawa reports on the 'use of numbers' by a chimpanzee[1].

Matsuzawa claims that the ape successfully identified six arabic numbers by selecting from a keyboard the numeral that was appropriate to the number of objects displayed. In addition, it provided the appropriate colour name and category label for some 300 sample types, stringing these into, for example, '3 red pens'.

The study is perhaps unique in requiring a level of description of an array of objects in terms of both numerosity and the type of object displayed. These findings are surely provocative, the fairgound appeal of an ape that selects numerals felicitously apart. Do they, however, imply that the chimpanzee is endowed with the rudiments of a system of calculation which finds a refined and rarified expression in the axiomatic systems devised by man? Only a convergent programme of comparative developmental research into the natural or intuitive calculus of animals and humans

will answer this question. Meanwhile, it is instructive to evaluate these and related findings in the light of current advances in child development, which already implicate some basic psychological mechanisms underlying mathematical understanding, particularly the conception of number.

Subitizing — the simultaneous apprehension of up to four elements through direct pattern recognition — is one rudimentary counting mechanism that has been identified in humans and is, perhaps, implied in the chimpanzee by Matsuzawa's study. The process is revealed by the measurement of the time it takes subjects to enumerate small numbers of items, such as dots, on a visual display. Increasing the number of items up to four has relatively little effect, adding around 200 milliseconds per extra dot with child subjects; above that number, however, each additional dot increases the enumeration time by over 1000 milliseconds. This 'break' in the range of times is consistent with the notion that subitizing, or simultaneous number perception, applies for up to four items, beyond which counting, a more costly procedure, begins.

It is impossible to evalutate the role of subitizing in Matsuzawa's study as identification measures are not reported. It is, however, interesting that the chimpanzee made by far the greatest number of mistakes (over 63 per cent) in the discrimination between numbers five and six, just outside the subitizing range for humans. It may be that the span of apprehension for apes is different from that of man. This needs to be determined empirically, and the research could also clarify the contentious relationship between subitizing and counting in the genesis of the number system[2].

Subitizing apart, developmentalists are agreed that even 'true' counting begins with small numbers. Many six-year-olds cannot count quantities above ten. Initially, there is an apparent need to use '1' as an anchor; asked to begin counting from a higher number, performance falters. And forward counting begins before counting backwards, which indicates that there is a preliminary temporal or serial-order basis for the number system. (It is interesting to note that temporal succession was suggested by both the philosopher Kant and the mathematician Hamilton as an intuitive basis for number.) The subsequent development of successor links in the counting chain seems to depend largely on a mental representation with (spatial) analogue properties[3]. This is inferred from the inverse relationship between the time taken to identify the greater of two numbers and their ordinal separation (for example, it takes longer to decide that 5>4 than 7>4) and suggests that there is a 'mental line' or scale on which numbers are mapped.

Such phenomena are seen to reflect important stages in the development of informal arithmetic skills, so their investigation in animals would help inform us whether a rudimentary calculus is shared with other species. Already, we have reported evidence for a representational device analogous to the 'mental line' (also based on decision-time data) for squirrel monkeys tested on a related symbolic (logic) task[4]. The expectation is therefore provoked that comparative research into number representation could reveal the communality of at least some counting mechanisms in humans and other primates.

The use of number, however, implies more than mere counting skill *per se*. Children count before applying their knowledge in situations where it would be desirable to do so. Asked to determine which of two rows of objects has 'more', four-year-old children tend to base their judgments on the shape of the set, selecting the more extended row and thus appearing to treat discontinuous quantities as continuous ones[5]. Yet children who fail in these tests can count under other circumstances. Should true counting be found in non-human primates, therefore, it would be necessary to evaluate their spontaneous use of counting as a measuring device, especially under conditions which afford other (if less reliable) solutions. □

Biopolymers

The spinning of silk

from Paul Calvert

SILK is stored as a concentrated aqueous solution in glands of the larval silkworm until it is spun as a dry fibre by a gentle waving of the head of the larva. The equivalent process for spinning a nylon fibre — the synthetic fibre that is closest to silk — consists in forcing the molten polymer out through a small jet, a spinneret, and cooling it. The resulting fibre is soft and not very strong, as it is not possible to run the polymer out through the small jet fast enough to align the molecules. Alignment is only achieved in a second process where the fibre is cold-drawn to about six times its original length, whereupon the molecules become oriented parallel to the fibre axis and the fibre becomes strong and stiff. So how does the silkworm manage to produce the same effect in a single step at room temperature? As silk fibres are insoluble in water, the solution stored in the silk gland must be metastable yet remain liquid until the mechanical process of spinning induces precipitation; no chemical change or drying seems to occur during spinning. But how does the apparently slow process of spinning a mobile liquid nonetheless result in a highly ordered fibre? And why does the production not become blocked up with the precipitating solid?

Most of the recent published work on the physiology of silk production has been carried out in Japan and much of it is summarized in a group of reviews in *Experientia* **39**, 441; 1983. Silkworm silk is secreted as a 15 per cent aqueous solution of fibroin in the narrow, convoluted posterior gland. From there it moves to the middle storage gland where the fibroin is enveloped in a solution of sericin that will ultimately become the gummy coating holding the fibres together in the coccoon. It is in the middle gland, where the concentration of silk rises to 30 per cent, that one might expect the polymer to be precipitated out. Akai (*Experientia* **39**, 443; 1983) describes the fibroin forming fibrous spherical masses of about 1 μm in diameter, but an electron microscope study of such a system is prone to artefacts and the conformation of the fibroin has been much debated.

In its most stable fibre form, silk has a β-sheet structure with chains extended and packed into layers. If the solution in the silk gland is removed and allowed to dry undisturbed, it forms silk I. Because this can only be obtained as crystal aggregates and not as oriented fibres (Lotz, B. & Colonna-Cesari, F. *Biochimie* **61**, 205; 1979), it does not lend itself to a complete X-ray structure determination. Nevertheless, a structure has been suggested in which the conformation of alanine and glycine residues are near the β-sheet and α-helix, respectively, and which is much more contracted than β-silk. But new data from magic-angle ^{13}C nuclear magnetic resonance instead suggest a loose 4-fold helix (Saito, H. *et al. Macromolecules* **17**, 1405; 1984).

In the liquid itself, the silk has been believed to be predominantly in a randomly coiled state with some α-helix, but another recent ^{13}C nuclear magnetic resonance study (Asakura T. *et al. Macromolecules* **17**, 1075; 1984) shows that it is randomly coiled in dilute aqueous solution and probably changes over to the loosely helical conformation of silk I as the concentration rises above five per cent, when the chains start to aggregate. This loose helix probably provides a conformational energy minimum that is readily reached and so prevents the chains from going over to the more stable β-sheet form and solidifying. The block copolymer structure of fibroin may help to stabilize the loose helix.

The concentrated liquid is certainly quite fluid: liquid readily flows out of the cut ends of glands of spinning silkworms (Magoshi, J., Magoshi, Y. & Nakamura, S. *Rep. Progr. Polymer Phys., Japan* **23**, 747; 1980). The precipitation step that occurs during spinning seems to depend on a critical shear rate being reached. *In vitro* measurements on solutions of less than five per cent show that precipitation occurs if liquid silk is sheared at rates greater than 50 s^{-1}. The silkworm spins the fibre at about 1 cm s^{-1} from the anterior gland, which narrows to 50 μm at the entrance. This corresponds to a shear rate of about 1 s^{-1} and causes precipitation of silk at the much higher concentrations found *in vivo* (Kataoka, K., & Uematsu, I. *Kobunshi Ronbunshu Engl. Ed.* **6**, 621; 1977). Magoshi *et al.* also report that the change to the β-sheet structures occurs at draw ratios of about four and that the silk can be induced to flow out of cut glands in a liquid crystal form.

From recent efforts to prepare high-strength synthetic fibres, it has become clear that to produce high levels of orientation the inter-chain forces must be controlled so as to permit slippage of the chains past one another while preventing rapid relaxation back to a randomly coiled state. Strong aromatic polyamide fibres such as Kelvar, are produced by spinning from liquid crystalline solutions in which the chains are locally aligned even before starting, thereby greatly increasing the orientation. Apparently silk production is similar, in that the aggregated state promotes local alignment of the chains while still keeping them in solution. They then easily spin to high orientations and to moduli that are comparable with the highest values achievable with nylons and about half those of Kelvar. The change from coiled to rigid conformation that happens with increasing silk concentration apparently corresponds to the 'induced rigidity', believed to occur in stiff polymers in solution (Matheson, R.R. *Mol. Cryst. Liq. Cryst.* **105**, 315; 1984). Again we have failed to recognize a natural process until rediscovering it the hard way. □

Icthyology

The biology of coelacanths

from Jared M. Diamond

ON 22 December 1938, a taxi driver on the docks of East London, South Africa, was hailed by a lady with a very oily dead fish that proved to be the coelacanth *Latimeria chalumnae*, sole survivor of a group of fish that had been believed extinct for 70 million years and traditionally considered close to the ancestor of all land vertebrates. Since then, many other specimens have been captured and pickled or frozen but scientists have yet to observe a healthy live specimen. But much has been learned from preserved specimens about ecology, sensory biology, reproductive biology, physiology, and taxonomic affinities of this 'living fossil'[1-3].

As for *Latimeria*'s geographical distribution and habitat, all but the first specimen were caught by native fishermen off two of the Comoro islands, between Madagascar and the east coast of Africa. Most specimens have been taken at depths of 100-300 metres as an accidental by-product of night fishing for oilfish, and the apparent restriction of *Latimeria* to these two islands is probably an artefact of how socio-economic and oceanographic conditions constrain the search for oilfish. The South African specimen taken 2,000 miles from the Comoros is the only proof of a wider distribution, but coelacanths may eventually turn up at other seamounts and banks in the western Indian Ocean.

Most likely, coelacanths perch on a reef, lunge for prey and suck it in, rather like a grouper[2]. They feed on fish and cuttlefish, swallowed whole, that live on or near the bottom of reefs in deep water. *Latimeria*'s most distinctive anatomical feature relevant to feeding is a joint across the skull that permits rotation by up to 15 degrees and thereby widens the gape and increases the strength of the bite[4]. Such intracranial joints are known from some fossil fish but no other living fish. Sensory equipment for prey detection includes large, nearly colour-blind eyes that are adapted to low light levels, densely packed rods but very few cones, and a large cavity in the snout, the rostral organ, which has the structure of an electroreceptor[5].

One of the most surprising discoveries about *Latimeria* concerns its reproductive biology. Initially, the coelacanth was assumed to lay eggs for external fertilization, like most fish, because males lack a penis, pelvic claspers, modified anal fins or any other obvious copulatory organ. Then, dissection of a female revealed shell-less and very large eggs, 8.5-9 cm in diameter[6]. Finally, Smith *et al.* proved that the eggs are fertilized and hatch internally by finding five miniature coelacanths, 30-33 cm long, in the oviduct of another female[7]. Dates of capture suggest that the gestation period is around 13 months. How the male achieves internal fertilization remains a mystery; two pairs of erectile caruncles flanking the cloaca may play a part[8,9].

The other big surprise concerns the osmoregulation of *Latimeria*. Living marine animals osmoregulate in one of three ways: by being iso-osmotic and similar in ion concentrations to sea water (hagfish and marine invertebrates); by being iso-osmotic, despite having ion concentrations far below those in sea water, through retaining urea and trimethylamine oxide (sharks); or by having ion concentrations far below those in sea water and being hypotonic but drinking sea water and excreting salt to remain in water balance (modern bony fish). *Latimeria* proves to resemble sharks rather than modern bony fish[10,11]. With 197 mM Na^+ and 187 mM Cl^- in its blood, as in bony fish, and 377 mM urea and 122 mM trimethylamine oxide, both the blood and urine of the coelacanth are iso-osmotic to sea water.

The osmoregulatory resemblance of *Latimeria* to sharks begs the question of its taxonomic affinities. Traditionally, coelacanths have been considered the sister group of the rhipidistians, an extinct group of bony fish that gave rise to amphibians and thence to other land vertebrates. Lagios, however, considers coelacanths the sister group of chondrichthyans (sharks and rays) on the basis of similarities not only in urea retention but also in pituitary structure, pancreatic structure and the presence of a salt-secreting rectal gland[2,12]. Other authors argue that these similarities do not necessarily ally coelacanths with sharks[2,10,13]. For example, urea retention arose independently in lungfish, certain frogs and some primitive ray-finned fish and so may also have arisen independently in coelacanths and sharks.

Thus, the dogma on which the current generation of biologists was reared — that coelacanths are close to the ancestors of tetrapods — is under vigorous debate. But the outcome is unlikely to shake their image as a symbol of long preservation without change. Thus, Time Magazine once branded Richard Nixon as a "coelacanth of American anti-communism", and a British MP ridiculed a fellow MP as a 'coelacanth' on the grounds that from his long silence in that august assembly it was a surprise to find him still alive[2]. Whether these calumnies of coelacanths are taxonomically justified is a question that can be resolved only when political conditions allow fresh specimens to be obtained from the Comoro islands or neighbouring waters. □

Destruction of fisheries in Africa's lakes

C.D.N. Barel, R. Dorit, P.H. Greenwood, G.Fryer*, N. Hughes, P.B.N. Jackson, H. Kawanabe, R.H. Lowe-McConnell, M. Nagoshi, A.J. Ribbink, E. Trewavas, F. Witte & K. Yamaoka

The introduction of the Nile perch into Lake Victoria, East Africa, has had disastrous consequences. Fisheries have been not merely damaged but destroyed. Lake Malawi has the world's most species-rich fish fauna and the prospect of introduction of alien species could mean disaster.

LAKE Victoria in East Africa, with an area of some 68,635 km^2, has a naturally rich and diverse fish fauna and formerly supported important fisheries, based largely on herbivores and detritus feeders of the family Cichlidae[1-3]. Fisheries based on such short food chains are ecologically the most efficient. Although over-fishing in Lake Victoria has for some time been a cause for concern, fisheries technology having advanced more rapidly than the scientific knowledge needed to devise rational means of exploiting this complex multispecific assemblage, a further serious hazard now faces the fisheries. In the 1950s, a suggestion was made that the Nile perch, *Lates niloticus* (Fig.1), a piscivorous species that grows to a large size, should be introduced into the lake. Although it was pointed out that simple ecological principles show that such an introduction would be detrimental[4] (yields of predators can never be as great as those of their prey), the idea was pursued by its supporters and in 1960 the Nile perch found its way into the lake, apparently from ponds into which it had already been introduced. Subsequently this species was deliberately introduced into the lake.

Since then the Nile perch has spread rapidly in the northern parts of Lake Victoria, having reached Kenyan waters by the mid-1960s. It is now abundant in many areas and is spreading south. It has invaded the Tanzanian waters of the lake and, in the early eighties, increased rapidly in numbers in the vicinity of Mwanza, where there are important fisheries based on indigenous species[5].

Invasion

The consequences of this invasion and of the establishment of the Nile perch are serious. While some of them were predicted, not all could have been anticipated. For example, the Nyanza (formerly Kavirondo) Gulf was the site of important fisheries for an endemic tilapia, *Oreochromis esculentus*, and for other fishes including the abundant haplochromine cichlids. Large quantities of the former supplied Nairobi and other centres of population and the latter, easily preserved and transported, were sold over a wide area. Since the arrival of the Nile perch, almost all the indigenous fishes of commercial importance have not merely declined but have virtually disappeared[6,7]. These include not only the herbivores but carnivores such as certain catfishes.

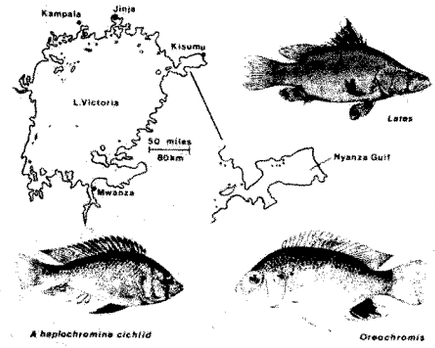

Fig.1 Lake Victoria and, inset, the Nyanza Gulf, the introduced Nile perch, *Lates niloticus*, and representatives of some of the cichlid fishes, formerly the basis of important fisheries in the Nyanza Gulf and elsewhere, that have recently declined catastrophically. Illustrations of fishes after Boulenger[20]. *Lates* reach up to 2 m long, *Oreochromis* up to at least 30 cm, and the many species of haplochromine cichlids are usually less than 20 cm in length.

Large numbers of *Lates* are being caught, however, reflecting the fact that they now make up well over 80 per cent of the fish biomass in the Nyanza Gulf[6], an atypical and clearly unsustainable role for a predator at the top of the food chain. When first introduced, *Lates* fed mostly on small haplochromines (Fig. 1), a group estimated formerly to comprise ~ 80% of the demersal fish stocks of the lake[8]. Having virtually eliminated this food source, small *Lates* now depend on the small prawn, *Caridina*, which is consumed by juveniles in several lakes. Recent observations show that ~ 80% of the diet of individuals less than 45 cm in length consists of these prawns and even fishes up to 100 cm in length are eating *Caridina*[6]. Large individuals are feeding predominantly on young of their own species.

Such a situation is inherently unstable and the ecology of the Nyanza Gulf has been irreparably upset. Furthermore, *Lates* is not liked by the local people, who constantly complain that they are unable to find their favourite food fishes. Prices are low: at the lakeside, a kilo of *Lates* sells for a shilling, but in areas where it is still available, a kilo of *Oreochromis* fetches 30 shillings. Moreover, because of its large size and oily nature, *Lates* cannot be sun-dried but has to be smoked, which is leading to the deforestation of a number of islands as trees are felled to produce firewood. The establishment of *Lates* has also had unfortunate sociological consequences. Fishermen who could formerly subsist on small-scale haplochromine and *Oreochromis* fisheries are being driven out of business and production is being concentrated in the hands of wealthier individuals who can afford the larger, stronger and more expensive nets required for *Lates*.

Fishery decline

Against this background, the conclusions of a symposium of the UN Food and Agriculture Organization (FAO)[9], held in October 1984, make curious reading. The symposium was convened under the auspices of the Committee for Inland Fisheries of Africa as the concern of its subcommittee for the development and management of the fisheries of Lake Victoria. Its purpose was to consider the status of the fish stocks of Lake Victoria, to suggest management measures, and to define priorities for research. Its report confirms that the fisheries, formerly based on a wide range of species or species groups, are now dominated by only four such groups, one of which, that comprising the haplochromine cichlids, "is itself threatened", and that fisheries for most species are in decline. The ill-advised trawl fishery for haplochromines was already in decline before the upsurge of the Nile perch and the report now admits that it is "almost certain" that haplochromine stocks cannot support the twin stresses of heavy predation by *Lates* and a fishery, and thinks it would be "extremely unwise" to invest further in this industrial fishery. In the Nyanza Gulf at least, the haplochromine fishery is already virtually nonexistent. It is admitted that, under what is seen as the best of two scenarios, production from Lake Victoria will settle down at a level "assumed to be some 80% less than the productivity achieved by the

pre-Nile perch community due to energy losses by the predator". Alternatively, in what is described as a boom or bust situation — another guess — the disrupting influence of *Lates*, which is admitted, is likely to lead to even lower productivity. Despite this it is claimed that "the introduction of Nile perch to utilize the haplochromine cichlids of the lake may be regarded as successful in terms of its original objectives"! With such criteria for success all things are possible. It is also claimed that losses in productivity "may, however, be compensated for by the greater value and quality of the fish caught". Lakeshore prices cast serious doubts on this prediction and no improvement of quality could compensate for the enormous losses in both yields and diversity brought about by the introduction of the Nile perch.

The establishment of *Lates* is not only an economic and ecological tragedy but also an enormous loss to evolutionary biology. Lake Victoria is the site of a remarkable radiation of cichlid fishes which has given rise to several hundred endemic species[10,11]. As an example of explosive speciation this assemblage is of immense scientific interest[12] and the loss of these fishes, often before their biology has been elucidated, is incalculable.

Irreversibility

We also wish to stress the irreversibility of introductions into large lakes — removal of *Lates* from Lake Victoria is now impossible — and to emphasize that the introduction of this fish is seen as a failure, not merely by a small group of concerned scientists who think they know best and who find the endemic faunas of African lakes of academic interest, but by the people it was meant to benefit. This is no minor incident but a disaster whose magnitude is put into perspective by noting that Lake Victoria is much larger than Switzerland.

Great damage has already been done to Lake Victoria, so it is disturbing to learn that the introduction into Lake Kivu of *Boulengerochromis microlepis*, the largest piscivorous cichlid fish of Lake Tanganyika, is now contemplated. Even more disturbing is the suggestion that the endemic pelagic zooplankton-feeding clupeid fishes of Lake Tanganyika should be introduced into Lake Malawi (= Nyasa). One of these, *Limnothrissa miodon* (Fig.2), has been successfully transferred to, and established in, the man-made Lake Kariba, and into Lake Kivu, a lake of recent origin with an extremely depauperate indigenous fish fauna, and which drains into Lake Tanganyika. These situations are utterly different from those prevailing in Lake Malawi. Malawi is an ancient lake in which evolution has given rise to exceedingly rich assemblages of endemic fishes, whose differentiation has proceeded further than in Lake Victoria, and of which it has more than any other lake in the world. These include a group of zooplankton-feeding

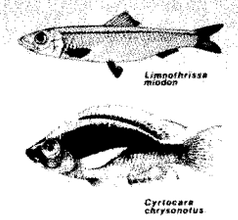

Fig.2 The zooplankton-feeding Tanganyikan clupeid *Limnothrissa miodon* (top, after Poll[21]) and one of the Utaka group of haplochromine cichlids (bottom, after Boulenger[20]) that occupy a similar niche in Lake Malawi.

haplochromines, the Utaka, that are caught for human consumption. Other zooplankton-feeders are also present, so the niche that would-be introducers wish to exploit is already filled. The great age of Lake Malawi has enabled its fishes to evolve into complex communities whose members interact in many subtle ways, and the effect of the introduction of alien species is impossible to predict. It is unlikely that a situation which has evolved over perhaps one to two million years can be improved by the introduction of an alien species whose impact can only be guessed at. The consequences could be disastrous and irreversible, as they have been in Lake Victoria, in the Laurentian Great Lakes of North America[13], Lake Titicaca (S. America)[14], Lake Lanao (Philippines)[15] and elsewhere. Similar concern has recently been expressed about introductions into Lake Kinneret, Israel[16]. The introduction of seemingly innocuous organisms, even those whose ecology has been much studied, can have unforeseen (and unforeseeable) consequences. Such have followed the introduction of the mysid crustacean *Mysis relicta* into certain lakes where it was hoped it would increase fish yields. For example, in one well-documented case it virtually eliminated planktonic cladocerans, an important food for fishes[17]. As a result a group of experts has unanimously approved a resolution that a complete moratorium be imposed on future introductions[18].

With one disaster accomplished in Africa, we urge those interested in improving the fisheries of Lake Malawi, whether in FAO or other bodies offering technical and scientific assistance, to concentrate on rational exploitation of the indigenous fish stocks, efficient distribution of catches and the reduction of unnecessary losses during preservation and storage. It is in addressing these questions, rather than in indulging in potentially dangerous introductions, that true progress can be made.

Lake Malawi is not only an important source of protein but is a site of international significance as a laboratory of evolution. Its future to the welfare of those who crop it, and to the international scientific community, is too important to be jeopardized by those who, with no means of predicting the consequences, would introduce alien fishes. We, of several nationalities, with experience of African lakes, therefore urge the governments of the states bordering Lake Malawi (one of which is Tanzania whose Lake Victoria fisheries are now threatened by the Nile perch) never to allow such introductions. The introduction of alien species could seriously jeopardize the food supplies and livelihoods of future generations. Such an action, the outcome of which is unpredictable, and scientifically indefensible, could prove disastrous to the continued existence of the viable Malawian fishery.

Conclusions

Fishes have often been moved from lake to lake, sometimes with the laudable goal of increasing the yield of human food. Except in fishless lakes and man-made reservoirs, such efforts have failed to achieve the desired objective, and sometimes the results have been disastrous. When large lakes whose fisheries are of immense importance as sources of human food are involved, especially in areas where other animal protein is scarce, much is at stake. A major scientific objection to such introductions is that the outcome is often unpredictable. Detrimental consequences can sometimes be predicted, as in the case reported here, but as controlled experiments cannot be carried out, and the reactions of the organisms involved cannot be determined in advance, a large element of guesswork is inevitable. The outcome is also often irreversible. An additional danger, not considered here, is that introductions may lead to the introgression of new genes. This can hamper taxonomic and evolutionary studies and hinder progress in aquaculture, as is happening among the economically important tilapiine cichlid fishes of Africa[19]. □

Does the ocean–atmosphere system have more than one stable mode of operation?

The climate record obtained from two long Greenland ice cores reveals several brief climate oscillations during glacial time. The most recent of these oscillations, also found in continental pollen records, has greatest impact in the area under the meteorological influence of the northern Atlantic, but none in the United States. This suggests that these oscillations are caused by fluctuations in the formation rate of deep water in the northern Atlantic. As the present production of deep water in this area is driven by an excess of evaporation over precipitation and continental runoff, atmospheric water transport may be an important element in climate change. Changes in the production rate of deep water in this sector of the ocean may push the climate system from one quasi-stable mode of operation to another.

MANY feedback loops that may amplify climatic change have been proposed, one of which has recently caught the imagination of palaeoclimatologists. Suggested by the atmospheric CO_2-content record recovered from the polar ice caps[1-3], this scenario involves interactions between climate and ocean circulation[4-7].

To appreciate the significance of the observations on polar ice, one must be aware of their context. Over the past several decades studies on deep-sea cores have provided a detailed history of climate during the past million years[8-10]. The first picture that emerged was that continental glaciers have waxed and waned on a timescale of 100 kyr[9]. These climate cycles are asymmetric, involving long periods of glacial buildup suddenly terminated with rapid warmings. Further work revealed that these long intervals of glacial buildup were modulated by cycles of ~20 and ~40 kyr duration[11,12], closely allied in timing and relative amplitude to variations in seasonal contrast produced by cyclic changes in the Earth's orbital elements[11,12]. Orbital forcing is accepted widely as the primary cause of glacial cycles (Fig. 1). Because the exact linkage between changes in seasonality and changes in climate has yet to be established, however, the issue remains open. Although it is plausible that nonlinearities in the response of snow and ice cover to seasonal variations drive glacial growth and retreat[13], it is not clear whether this mechanism alone is sufficient to do so.

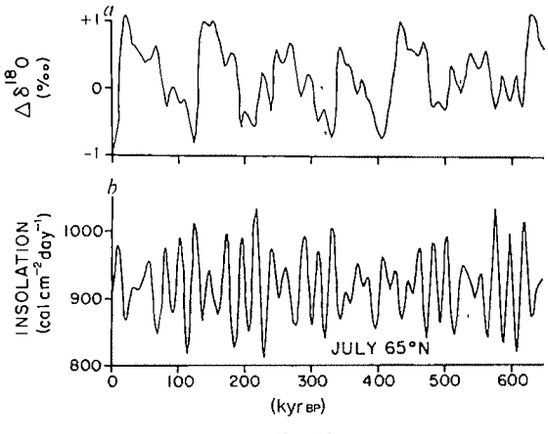

Fig. 1 *a*, Composite of the $^{18}O/^{16}O$ record for planktonic foraminifera from several deep-sea cores[12] This record primarily reflects changes in the amount of continental ice in the Northern Hemisphere The more positive the $\delta^{18}O$ value, the more ice. *b*, Variation with time of the July insolation at 65° N (ref 51) The rapid disappearances of the ice that terminate the episodes of very large ice cover correspond to prominent peaks in summer insolation for the latitudes at which the excess ice was located. In addition, there is a strong coherence between the ~20 and ~40 kyr spectral components of ice volume and insolation records Taken together these ties between insolation and ice volume have convinced most scientists concerned with palaeoclimates that the Earth's glacial cycles are driven by changes in seasonality brought about by cyclic changes in the Earth's orbital elements

Ice-core record

Scientists examining the oxygen isotope record preserved in ice cores from Greenland and Antarctica (see Fig. 2), checked whether the major features of this record matched those found in the deep sea. In one sense they did match. Glacial conditions prevailed from before 50 to ~10 kyr BP at which time a transition to interglacial conditions occurred. Once this transition was complete, climate remained remarkably uniform. No evidence for the 20 and 40 kyr cycles characteristic of orbital forcing appears in the ice-core record, in part because the record extends to only ~100 kyr BP and in part because of the exponential foreshortening with depth of the thickness of ice representing a single year. This flow-induced distortion produces a considerable uncertainty in the ice-core chronology before 10 kyr BP.

Although not showing the orbital periodicities, the ice-core record for glacial time does show many brief events during which climatic conditions returned about halfway to their interglacial state Because such events would be blurred totally by the stirring of worms in all deep-sea sediments with typical accumulation rates (that is, a few centimetres per kyr), this finding is not in conflict with the marine record. However, as

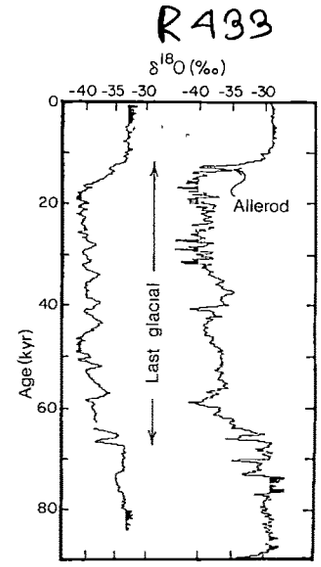

Fig. 2 Oxygen isotope records for ice cores[43] from Camp Century, Greenland (on the right) and Byrd Station, Antarctica (on the left) These records reflect mainly changes in air temperature over the ice cap. The more negative the $\delta^{18}O$ value, the colder the air temperature. The timescales are very approximate as there are as yet no direct radiometric ages for the glacial sections of the ice. Note that the glacial portion of the Greenland record shows a number of events of <1,000 yr duration. These events are muted (or absent) in the Antarctic record.

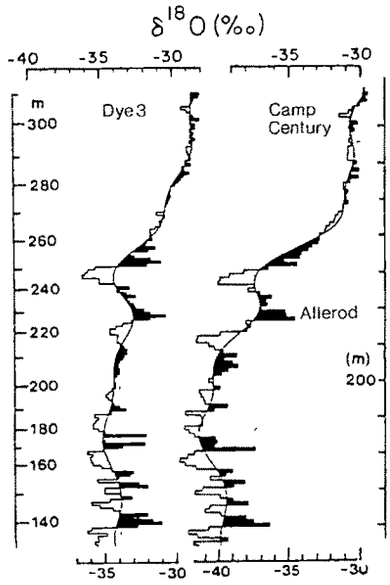

Fig. 3 Comparison between the $^{18}O/^{16}O$ records for the Camp Century and Dye 3 sites in Greenland for the time period ~40 to ~8 kyr BP. For each core a depth scale (metres above bedrock) is given After some adjustment of the Dye 3 depth scale a good match is achieved between the records in the two cores (Results obtained by Dansgaard *et al*[14])

these idiosyncrasies of the ice-core record were not seen in other records, the initial temptation was to pass them off as climate 'noise' without global significance. A rapid succession of findings has since changed this view of the noise, now the focus of much interest.

First, $^{18}O/^{16}O$ measurements by Dansgaard *et al.* on a second long core from Greenland[14] revealed the same events as the first (see Fig. 3), indicating that the events were both real, and occurred throughout Greenland Second, the events were recorded not only by $^{18}O/^{16}O$ ratio changes but also by dust[15], ^{10}Be (ref. 16), SO_4, NO_3 and Cl content[17] changes in the ice. The ice formed during the warm events is similar to interglacial ice with respect to these properties. Third, the $^{18}O/^{16}O$ pattern found for the most recent Greenland event was also recorded in $CaCO_3$ from lake sediments in Switzerland[18], which gave credence to a correlation made early on by Dansgaard *et al.*[19] (see Fig. 4). In interpreting their $^{18}O/^{16}O$ results for the Camp Century Greenland ice core, they suggested that the strong oscillation just before the onset of postglacial time was a record of the Alleröd-Younger Dryas oscillation seen in pollen records throughout Europe. During the Alleröd, trees abruptly replaced the grasses and shrubs that had characterized glacial time, only to be replaced by the cold flora characteristic of glacial time (see Fig. 4). This so called 'Younger Dryas' cold period lasted ~800 yr (that is, from ~11 to ~10.2 kyr BP) before Holocene forests appeared. However, these results did not influence broader thinking about glacial cycles and their causes.

A few years earlier Berner *et al* found that the CO_2 content of the air trapped in ice from the glacial sections of the Greenland and Antarctic cores was about two-thirds that for air trapped in ice from the interglacial sections[1]. Intrigued by the $^{18}O/^{16}O$ events found in the ice and the apparent correlation of the last of these with an oscillation in plant cover seen throughout Europe, Oeschger and co-workers found that there were CO_2 changes associated with these events[20,21]. In the Dye 3 core, oscillations (as recorded by the $^{18}O/^{16}O$ ratio) were accompanied by CO_2 oscillations of ~60 p.p.m (see Fig. 5). The CO_2 change was about two-thirds of the change that accompanied the major glacial–interglacial transition[1-3]. Although Fig. 5 shows only the CO_2 records for the oscillations within glacial time, a similar CO_2 change is found during the Alleröd-Younger Dryas interval at the end of glacial time[20].

Oeschger and co-workers are now searching for the CO_2 events in ice cores from the Antarctic. Whereas the other changes found in Greenland (that is, ^{18}O, ^{10}Be, dust, etc.) may have been restricted to the region under the influence of the northern Atlantic, the CO_2 change must, of course, be global Until confirmed in Antarctic ice, the possibility remains that the sharp changes in CO_2 content found in Greenland are artefacts of summer melting, which may have occurred during the warm events as it did at this low elevation site during much of the Holocene. We emphasize that although it was the discovery of CO_2 events that prompted serious consideration of possible ocean circulation–climate linkages, our speculations below about possible multiple climatic modes do not depend on the validity of the CO_2 changes.

Causes of atmospheric CO_2 change

The finding from ice-core studies that the CO_2 content of air extracted from glacial ice was lower than that extracted from postglacial ice[1-3] stimulated investigations as to the origin of natural CO_2 changes, which must be rooted in ocean chemistry[22,23]. The first scenario for the 90-μatm rise in CO_2 content at the close of glacial time called for the deposition of organic residues on the coastal shelves during the transgression of the sea that accompanied deglaciation. The subsequent finding of brief CO_2 events within glacial time, however, led to a re-examination of the question. If these CO_2 changes are typical of the atmosphere, then explanations involving the transfer of nutrient substances between the ocean and its shelf sediments must be abandoned. Such transfers could certainly not occur fast enough to produce 60-p.p.m. CO_2 changes in ~100 yr. To be viable, hypotheses will have to invoke redistributions of C, P and fixed N in the sea. Such redistributions are feasible if the ocean mixing and/or biological cycling change substantially[4-7,24]. This explains why CO_2 measurements on ice cores

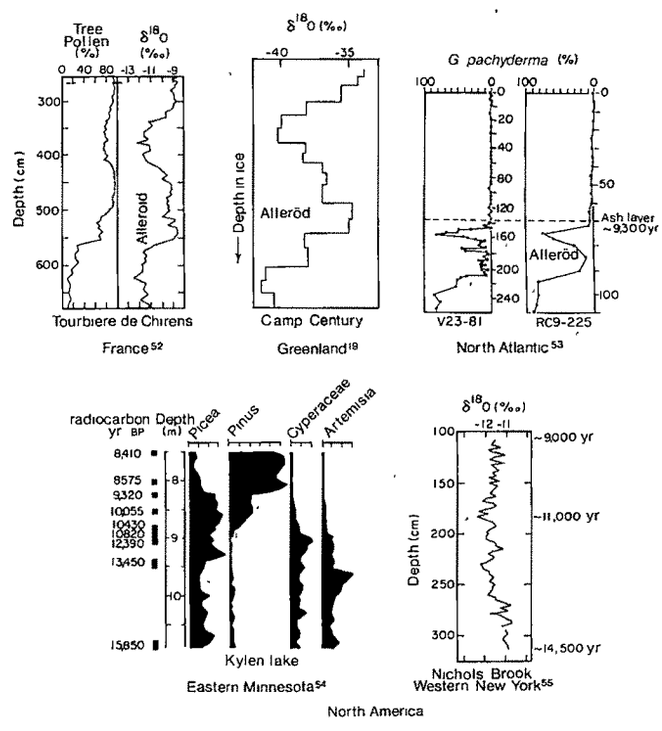

Fig. 4 Examples of records for the time period 13–9 kyr BP from Europe (pollen and $^{18}O/^{16}O$ in $CaCO_3$), Greenland ($^{18}O/^{16}O$ in ice) and the North Atlantic (% *G. pachyderma* in the planktonic foraminifera). All show the pronounced Alleröd-Younger Dryas oscillation By contrast no such oscillation is seen in either pollen diagrams or $^{18}O/^{16}O$ records from the United States

suggested links between climate and the joint operation of the atmosphere and ocean system.

Three quite different scenarios have been proposed. Broecker[24] pointed out that the evidence from deep-sea cores cited in support of his shelf-deposition hypothesis could also be explained by a change in the C to N and/or C to P ratio in the organic residues falling to the interior of the sea. A 30% decrease in this ratio was needed to explain the CO_2 drop at the end of glacial time.

Broecker and Takahashi[4] pointed out that a change in the transfer rate of water between the cold- and warm-water spheres of the ocean would produce a redistribution of ΣCO_2 between these reservoirs and a consequent change in atmospheric CO_2 content. The reason is that the biological 'pumping' of carbon by organisms from the surface ocean to the deep ocean is compensated partly by a flow of CO_2 through the atmosphere from the cold- to the warm-water sphere. Hence, a change in the rate of transfer of water between these spheres alters the balance between these two competing effects. To explain the lower CO_2 content during glacial time, Broecker and Takahashi invoked a several-fold higher rate of transfer of water between these spheres.

Three groups[5-7] have arrived independently at a different ocean scenario. Having pointed out that a reduction in the NO_3 and PO_4 contents of polar surface waters (that is, more effective biological use) would produce the desired glacial CO_2 reduction, all three groups demonstrated that a decrease in the rate of exchange between polar surface waters and the rest of the ocean may result in reduced nutrient content of polar surface waters and, in turn, of the CO_2 content of the atmosphere.

As the Broecker–Takahashi (B–T) ocean mixing scenario requires enhanced mixing during glacial time whereas the Princeton–Bern–Harvard (P–B–H) scenario requires reduced mixing, the balance of evidence must be carried by marine sediments, which would allow one of these hypotheses to be eliminated. Indeed, the P–B–H hypotheses predict higher than Holocene $\delta^{13}C$ values for planktonic forams grown in the Antarctic during glacial time whereas the B–T hypothesis predicts lower values. Unpublished ^{13}C results by N. Shackleton and R. Fairbanks on planktonic foraminifera from Antarctic deep-sea sediments strongly suggest that the reduction in surface water nutrient content required by the P–B–H hypotheses for glacial time did not occur. Radiocarbon age differences (determined by accelerator mass spectrometry) between planktonic and benthic forams from glacial horizons in deep-sea sediments eventually may provide another basis for making a distinction[25,26]. It is possible that neither of these scenarios is correct.

Although little is known about either ocean circulation or biological cycling in the past, one important clue has been found.

Table 1 Freshwater budget for the North Atlantic Basin, including the Arctic, Mediterranean and Caribbean

Source	Input rate fresh water (m yr^{-1})	Freshwater flux (sverdrup)
River runoff[50]	+0.21	+0 33
Precipitation[50]	+0.87	+1.36
Evaporation[50]	−1.21	−1.89
Mediterranean exchange*	−0 07	−0.10
Net†	−0 20	−0.30

The combined area of the North Atlantic basin (0°–80° N) excluding the Mediterranean Sea is $4\,9\times10^{13}$ m^2. For freshwater flux, 1 sverdrup represents a flow of a million cubic metres per second.

* The exchange between the more salty waters of the Mediterranean Sea and the less salty waters of the open Atlantic leads to a loss of fresh water from the Atlantic. This process is driven by the high evaporation rate (relative to precipitation and runoff) for the Mediterranean Sea.

† Using a deep water production rate in the northern Atlantic of 20×10^6 m^3 s^{-1} and a salinity excess for this water of 0.50‰, a fresh water flux of 0 3 sverdrups would be obtained, indicating that no large discrepancy exists between oceanographic and meteorological budgets

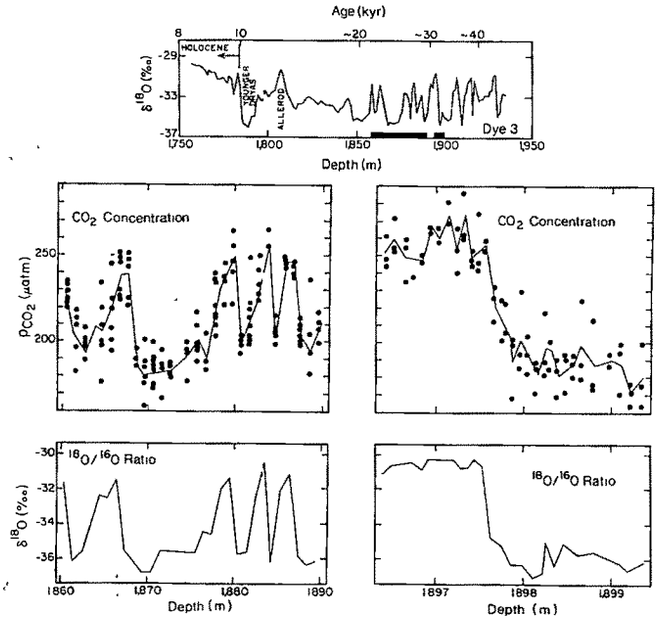

Fig. 5 Detailed P_{CO_2}–$\delta^{18}O$ comparison for two sections of the Dye 3 Greenland core[20,21] The location of these sections are shown in the upper panel by the dark bands. The longer band represents a time interval of ~8 kyr and the shorter a time interval of ~2 kyr The sudden air temperature warmings indicated by the rise in ^{18}O are accompanied by sharp rises in CO_2 content of air trapped in the ice (CO_2 results obtained by Oeschger *et al*)

Evidence from faunal, chemical[27] and isotope studies[23,28–31] of deep-sea sediments suggests that the production of deep water in the northern Atlantic, of great importance to the present-day circulation scheme, was reduced greatly during the peak glacial time. Most convincing is the finding by Boyle that the Cd content of benthic foraminifera from the Atlantic Ocean was higher during glacial time than today[27]. In the present-day ocean, the Cd and PO_4 contents of various water types in the sea are correlated almost perfectly. Thus, the Cd distribution in the glacial ocean is a good substitute for the P distribution. Boyle has demonstrated that the Cd/Ca ratio in benthic foraminifera is proportional to the corresponding ratio in the water in which they grow. In the present-day ocean, the low PO_4 and Cd content of Atlantic relative to Pacific deep water is attributable directly to the formation of deep water in the northern Atlantic. The reduction in this difference (suggested by the glacial foram results) is thus indicative of a reduction in the magnitude of the deep-water production in the northern Atlantic at that time.

Taken together, these arguments for the reduction of deep-water production in the northern Atlantic during glacial time are convincing. Is it possible then that the brief warm events recorded in the ice cores represent periods during which the glacially weakened northern Atlantic deep-water source was rejuvenated?

Distribution of oscillations

Adequate records are available currently to provide a picture of the geographical distribution for only the most recent fluctuation. This last oscillation appears in the records from both the Camp Century and Dye 3 cores from the Greenland ice cap and is found in pollen and $^{18}O/^{16}O$ ratio records from bog and lake sediments in western Europe. Evidence is also found in sediments in the northern Atlantic with an unusually high accumulation rate. Ruddiman and McIntyre showed that ~13 kyr BP the boundary between polar waters and temperate waters moved from its glacial position to near its present position (see Fig. 6), and remained there ~1 kyr before returning to its glacial position for several hundred years[32]. Finally; it returned to its present position where it remained throughout the Holocene.

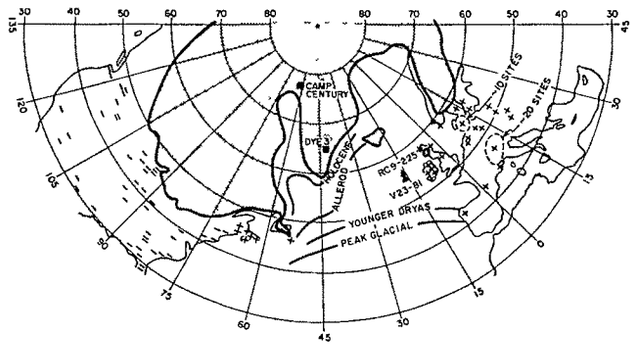

Fig. 6 Map showing the locations of sites at which sediments spanning the 13–9 kyr BP time interval have been studied[33–36]. At sites designated by a+ an oscillation in climate corresponding to the Alleröd–Younger Dryas is found. At sites designated by a− this oscillation has not been reported. The stipling corresponds to the area covered by ice just before the onset of the Allerod[56]. Positions of the polar front in the northern Atlantic during peak glacial, Alleröd, Younger Dryas and Holocene time, as reconstructed by Ruddiman and McIntyre[32], and the locations of the two long ice borings in Greenland and of the two ocean cores referred to in Fig. 4 are shown.

There are >50 European sites whose pollen records contain an oscillation in the 13–10 kyr period[33]. In contrast to the European pollen record is the lack of evidence for this event in the United States[34]. Recent research on cores from lakes and bogs in New Brunswick, Nova Scotia and Newfoundland[35,36], however, indicate that the oscillation was felt in the eastern regions of maritime Canada. This evidence is summarized in Fig. 6. Thus, as proposed by Mercer[37], we may be dealing with a regional change in climate involving primarily the area under the climatic influence of the northern Atlantic Ocean. Because evidence for such an oscillation has been found elsewhere, that is, in the cordillera of South America[38–41] and in New Zealand[42], the situation may well be more complicated. This event is muted or absent in the $^{18}O/^{16}O$ ratio for the Byrd Station Antarctica record (see Fig. 2)[43].

Climate impact of deep-water production

The turning on and off of deep-water production in the northern Atlantic would be expected to produce a regional climate change. The rate of production of deep water is now ~20 Sverdrups (that is, 20,000,000 $m^3 s^{-1}$)[44] The water feeding the source region for the deep water has a temperature of ~10 °C, whereas the new deep water leaving the region has a temperature of ~2 °C. Thus, as a byproduct of deep-water formation ~5 × 10^{21} cal of heat are released to the atmosphere each year, an amount corresponding to ~30% of the solar heat reaching the surface of the Atlantic Ocean in the region north of 35° N.

To test the geographical distribution of the impact of turning on and off this source of heat, an experiment was performed using the general circulation model for the atmosphere developed by the Goddard Institute for Space Studies. A comparison was made between the air temperature for a model run with present-day ocean conditions and for a model run with the surface ocean temperatures in the region north of the glacial polar front (see Fig. 6) cooled to the levels estimated by the CLIMAP (1981) reconstruction for glacial time[45]. The results of this experiment will be published elsewhere. The air-temperature anomaly generated by this change in sea surface temperature spreads across Europe. A cooling is seen in extreme north-eastern North America whereas no corresponding anomaly is seen in the United States or over Antarctica. The results are, therefore, consistent with the pollen and ice-core evidence. Although this experiment does not prove that the Alleröd–Younger Dryas event was caused by changes in the rate of deep-water production in the northern Atlantic, it does suggest that were such changes to have occurred they would have produced climate changes with the observed regional pattern.

Deep-water production changes

The most difficult question is why the production of deep water in the northern Atlantic may have resumed for brief intervals during glacial time. For an answer, we must consider the processes important to the present-day production of deep water in the northern Atlantic and for the absence of equivalent production in the northern Pacific. Oceanographers agree that the contrast between the two northern oceans is rooted in the large salinity difference. The waters of the northern Atlantic are saltier than the mean for the upper ocean, whereas the waters of the Pacific are fresher. The Atlantic's extra salt allows waters of density as great as any found in the deep sea to be generated during the winter months. By contrast, even if cooled to their freezing point, northern Pacific waters achieve a density no greater than that of intermediate depth water.

An approximate fresh water budget for the northern Atlantic and its satellite sea, the Mediterranean, is given in Table 1. Despite the fact that this region receives a sizeable portion of the world's river runoff, it loses an even greater amount of water through an excess in evaporation over precipitation. The resulting net loss of fresh water leads to the salt enrichment observed in the northern Atlantic. The salt budget for the North Atlantic must be balanced by the export of salty deep water to the Pacific and Indian Oceans. On a global scale, the water (and salt) budgets of the surface ocean must balance; thus, the fresh water lost from the Atlantic must re-enter the ocean elsewhere. Polewards of 30° N, atmospheric transport produces a net divergence of water vapour over the North Atlantic and convergence over the North Pacific east of the dateline[46]. Thus, if we are to understand what maintains deep water production in the present-day ocean, we must understand why fresh water is being pumped through the atmosphere from the North Atlantic to the North Pacific.

Warren, addressing this question[47], has shown that this pumping can be explained nicely by the temperature difference between the two oceans. The waters north of 30° latitude in the Atlantic are warmer than their Pacific counterparts. Thus, water is being distilled off the 'warm' Atlantic and condensed on the 'cold' Pacific. If so, then it is the temperature difference on which we must focus. What maintains it?

To some extent the warmer temperatures for the surface of the northern Atlantic must be related to the deep-water formation process. Upper waters in the Atlantic are advected northward into the regions of deep-water production. This advection carries heat to high latitudes. By contrast, in the northern Pacific, deep water upwells to the surface and is carried southward in the upper ocean. In this sense the situation is self-sustaining. Stommel[48] and Rooth[49] have discussed the possibility that thermohaline circulation has more than one stable mode The deep-water circulation pattern maintains surface temperature of the northern Atlantic at a higher value than that for the Pacific. This temperature difference causes the Atlantic to be enriched in salt, whose excess leads to deep-water formation. At steady state, deep-water production must carry away just the amount of excess salt left behind by the atmospheric transport of water from the Atlantic to the Pacific. The standing excess of salt in the northern Atlantic is presumably just high enough to allow the generation of water sufficiently dense to enter the deep Atlantic.

This brings us to the fundamental question of this review—does the ocean–atmosphere system have more than one mode of operation? The idea that the Earth could, under the same solar heating regime, have quite different temperatures depending on its ice albedo or atmospheric greenhouse gas content is not new. Climate modellers have long been aware of the white Earth catastrophe scenario. If somehow the Earth were to be covered with ice, the greatly increased reflectivity of its surface would cause the temperature to fall below the freezing point and thereby stabilize the change. They have also considered the

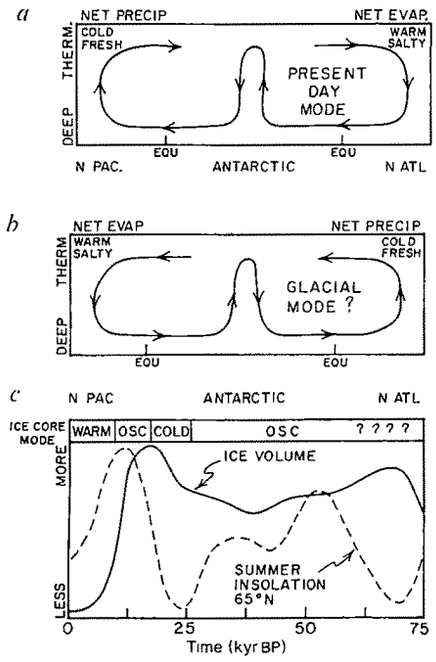

Fig. 7 *a*, *b*, Two possible extreme modes of ocean circulation are proposed here, corresponding to the warm and cold intervals seen in the ice-core record. *c*, The times when the ice-core record shows the system to have been locked in its warm mode, to have been locked in its cold mode or to have been oscillating between these modes are shown with the ice-volume record and the Northern Hemisphere high-latitude summer insolation record. The intervals of warm Greenland climate correspond to intervals of low ice volume and high summer insolation and the intervals of cold Greenland climate correspond to times of high ice volume and low summer insolation. The intervals when Greenland climate oscillated between warm and cold corresponded to times when the ice volume–summer insolation product had intermediate values. This suggests that the atmospheric transport of water vapour between the Atlantic and Pacific changes with ice cover and summer insolation.

greenhouse catastrophe. If somehow the carbon locked up in sediments were to be released to the atmosphere, the enhanced infrared absorption would raise the planetary surface temperature to the point where carbonate minerals and organic residues could no longer form and thereby stabilize the change. Based on the CO_2 results from ice cores, Oeschger suggested that the Earth had two modes of ocean–atmosphere–biosphere–cryosphere operation. Each oscillation observed in the ice cores involves a jump from one mode of operation to the other.

It is tempting to speculate that one of Oeschger's two modes corresponds to the situation when deep-water production in the northern Atlantic is 'strong' and the other to the situation when deep-water production is 'weak'. If this is the case, then the palaeoclimatic record tells us that, for the summer insolation and ice-cover situation that prevailed during the full interglacial time, the system was in the 'strong' mode and for the corresponding situation that prevailed during full glacial times it was in the 'weak' mode. Because in the present-day ocean the deep-water production corresponds to salt enrichment in the Atlantic, it is tempting to postulate that during full glacial time the opposite was true. Then, salt was being enriched in the Pacific and deep-water flow was the reverse of what it is now (see Fig. 7). Based on oxygen isotope studies on North Pacific cores, deep water may have been produced in the Pacific Ocean during glacial time (N. Shackleton, personal communication). On the other hand, it is possible that the rate of salt enrichment in the Atlantic was considerably less during glacial time, causing a reduction in deep-water production rather than a reversal in flow. Boyle's Cd data favours this latter point of view.

The Oeschger climate oscillations occur in intervals with climates lying between those characterizing full glacial and full interglacial time. If, as the summer insolation at high northern latitudes increased and once again the atmospheric vapour transport balance favoured salt buildup in the Atlantic, then the production of deep water would resume (or intensify), releasing excess heat to the atmosphere over the northern Atlantic. This excess heat would lead eventually to increased discharge of ice from the caps surrounding the Atlantic. If 3% of the excess ice present during full glacial time were added to the Atlantic Ocean by melting during a 100 yr interval, the mean freshwater flux would be 0.6 sverdrups (that is, twice the present imbalance between fresh water and loss for the Atlantic). Thus, the melt water generated in this way would significantly reduce deep-water production, returning northern Atlantic climates to their glacial state. This, in turn, would halt ice retreat and allow the northern Atlantic salt buildup to resume. Thus, it is possible that during periods of ice retreat the system oscillates between the North Atlantic 'strong' and 'weak' modes of deep-water production. Although the physics of such an oscillation has yet to be elucidated, two elements are evident. The first involves water storage in and release from the large Northern Hemisphere glacial ice caps adjacent to the Atlantic. The other involves the transport of salt through the deep sea. As water now resides for many hundreds of years in the deep sea, transients in the deep-ocean salinity distribution created by ventilation changes may be an important element in the oscillator.

Climate modelling

Until now, our thinking about past and future climate changes has been dominated by the assumption that the response to any gradual forcing will be smooth. But if, as proposed by Oeschger, the system has more than one quasi-stable mode of operation, then the situation is more complex. Present general circulation models will at best allow us to study only the changes that will take place if the system remains in its current operational mode. Thus, if the changes that characterized glacial time and those that will characterize the coming CO_2 superinterglacial time involve mode switches, investigations of the transient climate response have to allow for this possibility.

Despite the tenuous nature of the information presently available and of the difficulties inherent in thinking in terms of mode changes, we must begin to explore this alternate track. The programme elements required are clear. At least we must have a joint ocean–atmosphere general circulation model that will allow the exploration of several possible connections between planetary radiation, atmospheric water transport, ocean circulation, atmospheric trace gas content and the marine and terrestrial biosphere. If we are to have confidence that these models provide reliable analogues to the real world, we must gather more information about how each of the important subsystems operates in the present. Finally, we must extract all possible information from the palaeoclimatic record. Even given the full use of present resources, it will be several decades before we possess sufficient understanding to predict future climates. Unless we intensify research in these areas, the major impacts of CO_2 will occur before we are prepared fully to deal with them.

Powerful extragalactic masers

Willem A. Baan

Arecibo Observatory, PO Box 995, Arecibo, Puerto Rico 00613, USA

Two strong extragalactic OH masers have been detected in the galaxies NGC3690 and Mrk 231 which are in the same class as the megamaser source IC4553 (Arp 220). The amplification model for the background continuum proposed for IC4553 can account for most of the powerful OH maser lines and for part of the H_2O emission. Most masing galaxies have sufficient infrared flux to pump the masing regions, except that the H_2O pumping must occur at a much higher conversion efficiency than the OH pumping.

THE extraordinary strength of the few OH and H_2O extragalactic masers[1–11] suggests that there are emission processes occurring in these sources which differ significantly from those that occur in galactic masers[12,13]. By far the most luminous OH maser detected to date is in the source IC4553 (refs 4, 14), whose maser emission is superposed exactly on the continuum source in the nucleus of the galaxy[14,15]. This strongly suggests the presence of amplification of the flux from the nuclear continuum source by a foreground molecular region. The masing region may have a relatively low gain and may not have been observable in the absence of the background source.

This article presents the recent detection of two powerful OH megamasers in the galaxies NGC3690 and Mrk231. Because of their similarity to the emission in IC4553, most of the powerful extragalactic OH maser emission can be interpreted with the continuum amplification model proposed for IC4553. This concept can be extended to the H_2O maser emission as well.

New detections

A search for OH absorption or emission in 110 galaxies with strong continuum sources in June 1984 used the 91-m telescope of the National Radio Astronomy Observatory (NRAO) in Green Bank, West Virginia, which brings the total number of galaxies searched at Arecibo and Green Bank to 240. A cooled gallium arsenide field-effect transistor receiver with a total system temperature of 27 K was used in combination with a 396-channel autocorrelation receiver, which was split in two banks for the two circular polarizations. The sensitivity of the 91-m telescope is 1.1 K Jy^{-1} at 18 cm. Very gentle third-order baselines were subtracted from the data.

Strong OH emission was detected in two systems, NGC3690 and Mrk231[16]. Several new OH absorption features were detected, among which are the line NGC3079[5] and a tentative detection in the H_2O maser galaxy NGC4258. The absorption results will be published separately (W.A.B. *et al.*, in preparation). The results on the new OH maser sources are summarized in Table 1 and Figs 1 and 2.

NGC3690. The nuclear activity in the interacting galaxy pair NGC3690/IC694 (Mrk171) is one of the prime examples of starburst activity[17]. The pair of Sc galaxies is depicted in plate 299 of Arp's catalogue[18]. NGC3690 exhibits the most luminous optical emission lines of any non-Seyfert Markarian galaxy[19] and is also a very strong infrared source[20–22]. The radio source in NGC3690 has a triple structure and the 10-μm emission and optical line emission are superposed perfectly on this triple[17]. Prominent neutral hydrogen absorption towards the radio nucleus of NGC3690 has been seen at the VLA[23]. This broad and deep absorption line has a double structure with a separation of 160 km s^{-1} and can most readily be interpreted in terms of nearly edge-on absorbing disks (in agreement with the optical image). Optical studies[24] also indicate a velocity spread across the nuclear region of ~125 km s^{-1} increasing to the west. NGC3690 is a strong CO emitter; emission of this gas follows the infrared and radio structure of the galaxy (P. Salomon, personal communication; W.A.B. and R. W. Freund, unpublished results). The CO emission also has two peaks at ~130-km s^{-1} separation.

The OH emission spectrum of NGC3690 is presented in Fig. 1. The 1,667- and 1,665-MHz lines are clearly visible in the spectrum and are merged slightly. The features have been verified recently using the Very Large Array (VLA)-A. The double structure in the 1,667-MHz line agrees quite well with the two H I absorption features. Assuming the high velocity OH component originates at the west continuum component and

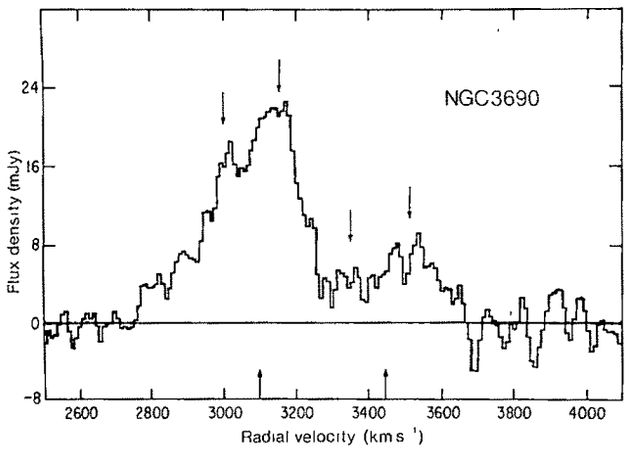

Fig. 1 The OH spectrum of NGC3690 obtained using the 91-m telescope of NRAO. The integration time is 59 min; the velocity scale refers to the 1,667-MHz feature. The 1,665-MHz feature is offset 351 km s^{-1} from the 1,667-MHz line The pair of long arrows indicate the centre velocity of the features. The two pairs of short arrows indicate the double structure found in the H I and CO features

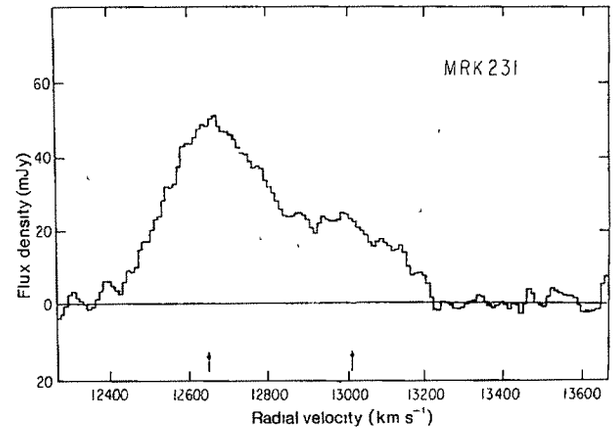

Fig. 2 The OH spectrum of Mrk231 The integration time for the spectrum is 29 min. The arrows indicate the centre velocities for the two features obtained with Gaussian fitting. The H I absorption velocity lies 14 km s^{-1} below this. The velocity scale refers to the 1.677-MHz feature.

the low velocity component at the east, the optical depths for the two components are ~−0.08 and −0.15, using the respective radio continuum fluxes. This suggests a correlation between the infrared flux and the maser gains, because the infrared flux from the west is ~2.5 times that from the east.

Mrk231. This is one of the most prominent Syl galaxies and is considered to be a prime example of Seyfert properties. However, Mrk231 is unique among Syl galaxies for its red colours and its strong interstellar absorption lines[25]. Most of its luminosity lies in the infrared[20,21]. The nucleus of Mrk231, having a strong unresolved radio source coincident with the optical continuum peak, cannot be modelled simply with bursts of star formation[26]. Nevertheless, Mrk231 is one of the few nuclei that shows both Seyfert 1 properties and evidence of star bursts[24].

Mrk231 has optical emission-line velocities that are different from the absorption-line velocities[27]. Broad H I absorption has been found at the lower redshift[23,28], suggesting the presence of an edge-on disk structure. Gaussian fits of the OH emission lines detected in Mrk231 (Fig. 2) indicate a velocity which is 14 km s^{-1} higher than the H I absorption velocity. For an isotropic emission pattern, the emission in the 1,667-MHz line alone is 2,500 $L_\odot$, which is 3.5 times greater than that of IC4553. The luminosities quoted for the masers are isotropic. It is, however, probable that the maser emission is not isotropic and that the beaming is different for the OH and the H_2O masers. Assuming that the maser emission in Mrk231 originates in a cloud that exponentially amplifies the continuum flux[29], the peak optical depth required for explaining the 1,667-MHz lines is −0.3. If all emission in Mrk231 occurs in front of the <0.3″ compact source the brightness temperature of the 1,667-MHz peak is >3.6×10^5 K.

OH megamaser IC4553

The case of the OH maser source in IC4553 may be taken as a basis for the discussion of extragalactic masers. IC4553 (Arp220) has been studied extensively in different wavelength regimes and the data reveal a rather complete picture of the properties of the different masing regions.

The galaxy IC4553 has been detected in emission at all four 18-cm transitions of OH. The two main lines have been presented earlier[4]. The 1,667-MHz feature has a peak strength, which is 0.82 of that of the continuum source, whereas the peaks of the 1,665-, 1,612- and 1,720-MHz lines are respectively 0.24, 0 08 and 0.03 of the 1,667-MHz peak flux (W.A.B., in preparation). VLA-A[14] and MERLIN[15] observations at 18 cm show that the line emission is exactly superposed on a triple continuum structure of 0.6×2.0″.

The high-resolution results indicate that the bulk of the masing material is part of a rotating molecular disk centred on the nuclear continuum source[14,15]. A second distinct emission region exists on the eastern side of the source, which has a radial velocity ~300 km s^{-1} higher than the systemic velocity of the molecular disk[14]. In H I the galaxy IC4553 displays a very strong and broad (740 km s^{-1}) absorption line[30] VLA-A observations[31] at 21 cm reveal that the bulk of the absorption also results from a rotating disk, which belongs to the same large-scale structure as the molecular disk and is centred on the nuclear continuum radio source. The high-velocity OH emission feature has also a counterpart in H I absorption

References are given in parentheses. The marginal detections of H_2O in NGC6946[6,7] and NGC6240[7] have not been included in the table.
* H I absorption in NGC3079 may be evident from the published spectrum of Shostak[62]
† The strength of the OH maser lines in N3079 is not yet known.
‡ A tentative detection has been made of OH absorption in NGC4258 (W.A.B., A. D. Haschick & J.T. Schmelz, in preparation).
§ $H_0 = 55\ km\ s^{-1}\ Mpc^{-1}$

The optical appearance of the galaxy IC4553 suggests that the galaxy is definitely the result of a recent merger (see plate no. 220 in Arp[18]). Recent optical studies indicate that the dark band, which divides the image in half, is a dust lane[32,33]. The disturbed appearance of the dust lane suggests a disk structure, similar to that seen in M82 (ref. 33). The outer optical structure resembles that of the merging pair in the 'Antennae' (NGC4038/9). The notion of tidal interactions is supported by the high velocity H I gas (in absorption) and OH gas (in emission). No H I emission has been seen in IC4553 (ref. 31).

IC4553 is a very prominent infrared source as has been found recently by IRAS[34] and ground-based instruments[35]. The infrared source in IC4553, with a minimum size of ~1.4" and a spectral temperature of 61 K (refs 34, 35), is centred on the position of the continuum source[32,34] in the centre of the dust lane. IC4553 is unique among the infrared galaxies because it has the highest known ratio of infrared luminosity to blue luminosity ($R_{ib} = 80$). This high ratio could indicate that a powerful burst of star formation is in progress. Optical emission lines suggest Seyfert-like (Sy2) properties, but they would not be inconsistent with an H II region spectrum[24,32,36]. Starburst models as well as Seyfert models (as needed for Mrk231) present difficulties in explaining IC4553 because of the heavy dust obscuration[24,36]. IC4553 exhibits strong H_2 emission[37,38], which could be explained by shock excitation of interstellar clouds. No flux was detected in a 455-min exposure in the short ultraviolet wavelength regime with the IUE telescope (W.A.B. and R. Panek, unpublished results).

There is still controversy as to the nature of the galaxy IC4553. The nucleus may be the advanced stage of a merger of two nuclei or the nuclear activity has been triggered by a tidal interaction, which also resulted in a disturbed outer structure. The radio and infrared sources could be evidence either of Seyfert activity or of a starburst embedded in the very dusty nuclear region.

Working model

On the basis of the observational results on the OH megamaser in IC4553, a model[14,15] has been suggested in which the bulk of the maser emission is caused by amplification of the radio flux from the nuclear continuum source by foreground molecular material. Here I apply this model to the two newly discovered OH masers and to extragalactic H_2O masers. The OH and H_2O molecules in molecular clouds may be inverted partially by the infrared radiation field or other pumping processes. This relatively weak population inversion occurs in relatively extended molecular structures, in contrast to the stronger but more localized population inversions around condensed H II regions which characterize masers in our Galaxy. Because of its low exponential gain, the molecular material is not observable as a maser when observed on its own. However, when a background source is placed behind the cloud, it can amplify the continuum flux to an observable level.

To obtain the correct configuration for continuum amplification the following ingredients are required: (1) the presence of a background continuum source, possibly in the centre of the galaxy; (2) a nearly edge-on molecular disk, thus increasing the probability of seeing a molecular cloud with an inverted population along the line-of-sight; (3) a pump for inverting the molecular material.

Below, I address these requirements in more detail and present the current evidence in support of such a model. Some of these characteristics have already been mentioned in relation to the masers in IC4553 (refs 14, 15, 32) and NGC3079 (ref. 5). The main characteristics of all prominent masing galaxies are given in Table 2.

Continuum sources. Most known masing galaxies are characterized by compact nuclear continuum sources, some of which also have an extended nuclear structure. However, the crucial question is where the maser emission occurs relative to the continuum source. In the case of IC4553, the maser emission is exactly superposed on the continuum structure and the emission and continuum contours are unmistakably the same[14,15]. Spectral line studies of the new OH maser sources at the VLA are not yet available, but the available evidence for NGC3690 strongly suggests that the OH emission originates at the location of the three continuum sources. Mrk231 has a compact nuclear radio source. In the case of M82 the OH maser emission does not

originate at the peak of the continuum map[2], but the continuum flux is still considerable at the maser locations and maser amplification is certainly plausible. For the H_2O masers, a coincidence of maser and continuum emission has been found in three cases. The prominent maser feature in NGC3079 (refs 4, 6) coincides with the nuclear source at 2″ resolution with the VLA-D (A. D. Haschick and W.A.B., unpublished results). Similarly, the prominent feature in NGC4258 falls on a weak source in the extended continuum structure, whereas the high-velocity feature in NGC1068 coincides with one of the eastern continuum knots (M. J Claussen, personal communication). VLBI and VLA-A studies are in progress to determine these relative positions.

Molecular disks. The main observable characteristics (besides the optical image) of seeing a galactic disk edge-on are high absorption column densities. Most masing galaxies show evidence of H I and/or OH absorption and some have the highest known H I absorption column densities. The masing galaxy with a low H I absorption column density, NGC1068, also has a relatively low inclination angle; a severe upper limit has been found for its OH absorption column density (ref. 39; W.A.B. *et al.*, in preparation). The molecular disk in our Galaxy is inclined by an angle of 25° relative to the H I disk[40]; this might be true for other galaxies. A recent compilation of all known OH absorption lines indicates a correlation of the OH absorption optical depth and the estimated inclination angle of the galaxy[3]. This result supports the notion that most of the absorbing OH molecular clouds are confined to a relatively compact disk, approximately aligned with the large-scale disk of the galaxy.

Pumping mechanisms. Here, I assume that the masing molecular gas is contained in molecular clouds that are not necessarily next to compact H II regions. Diffuse molecular gas can have maser action, as has been seen for the galactic molecular clouds along the line-of-sight to the continuum source 3C123 (ref. 41). The 1,720-MHz emission line is found to be stronger on-source than off-source, which can be readily explained with weak amplification at 1,720 MHz of the continuum flux of 3C123 as it passes through the molecular cloud. This is the only known definite example (besides IC4553) of amplification of a background continuum

The pumping agent for the OH in molecular clouds is probably the far infrared radiation from dust[42,43]. For IC4553, all four 18-cm OH transitions have been seen in emission, which is unusual because generally either 1,720 MHz or the other three lines are in emission, but not all four. The pumping of H_2O masers is still subject to study. For H_2O/H II masers it is difficult to explain how such large maser fluxes emerge from clouds of such small sizes. Collisional processes may be the dominant pumping mechanisms for H_2O masers[13].

Most galactic OH and H_2O masers are thought to be saturated[12,13], which means that there is a steady production of photons throughout the masing region. Saturated masers have a high efficiency of converting pump photons into maser photons. Unsaturated masers have an exponential gain but have a lower conversion efficiency. However, an unsaturated maser can amplify background continuum radiation. As the line radiation field in the maser gets stronger, the maser will eventually saturate. The presence of a background continuum may bring this about earlier. An observer will then see the (saturated or unsaturated) masers superposed on the continuum source. Without a background, source the masers may not saturate at all and even be unobservable. This situation may exist in the H_2O sources NGC3079 (ref. 5) and NGC4258, where narrow features could represent (mostly) saturated masing pockets of gas, whereas broader features represent (mostly) unsaturated amplification of the radio continuum. The OH maser lines are generally broad and could mainly result from amplification of the background source. Naturally broad OH lines may also have some high brightness saturated features embedded in them. Using the presently known sizes (upper limits) for the continuum sources, one finds a brightness temperature $T_b < 10^7$ K for the masers, which is considerably below those of saturated galactic masers ($T_b = 10^{10}$–10^{11} K; ref. 12). Much will be learned from VLBI observations as they will reveal the compact and more saturated components.

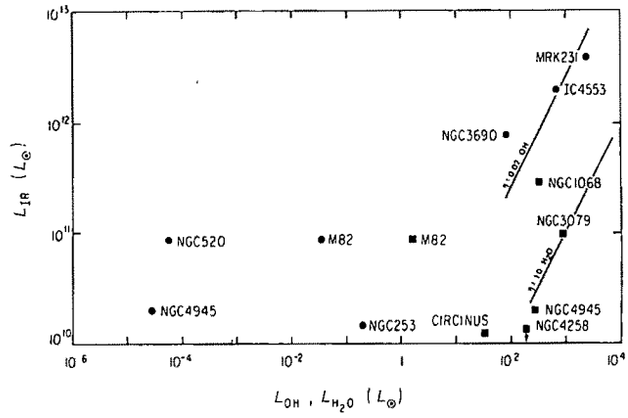

Fig. 3 Relation between the isotropic OH and H_2O luminosities and the integrated infrared luminosity. The circular entries are for OH masers and the square entries are for H_2O masers. The linear relationships in the diagram represent constant conversion efficiency curves for the OH and H_2O masers. For determining these curves the linewidth has been taken to be 300 km s^{-1} for the OH masers and 100 km s^{-1} for the H_2O masers.

A general problem for galactic masers is the absence of an identifiable pump source, in particular of a sufficient infrared flux. However, this is not the case for the extraglactic maser sources, which tend to have prominent infrared sources mostly at the location of the radio continuum sources (that is, NGC3079, NGC3690, IC4553, Mrk231). In Fig. 3 the OH and H_2O maser luminosities have been plotted against the infrared luminosity of the galaxy. The low luminosity masers seem to be independent of L(IR). However, the high luminosity masers show an approximately linear increase in luminosity with increasing L(IR). Such a linear relationship is expected and observed for saturated stellar masers, but seems also plausible for unsaturated masers. Two pump efficiency curves based on the spectra of the prominent maser galaxies (IRAS point-source catalogue) indicate that the OH masers may have an efficiency of a few per cent for converting photons at 30 μm into OH maser line photons. However, if the inferred radiation field at 10 μm pumps the H_2O maser, this should happen at a conversion efficiency of 50–100%. These conversion efficiencies are typical for unsaturated and saturated masers, respectively. Naturally collisional processes can also contritube to the pumping of the water vapour. Evidently, OH and H_2O masers have different pumping mechanisms and efficiencies, or the H_2O masers may be more directional (thus resulting in a overestimate of the luminosity). The low luminosity maser sources may result from similar large-scale processes, but they can also be just like the powerful masers seen in our Galaxy,

OH and H_2O masers

It is apparent from the above discussion that the properties of the OH maser sources and those of H_2O are similar in many ways. Because of these similarities, I suggest that the basic model, amplification of the background source flux, may apply to both types of sources. However, some maser characteristics are different, indicating that different physical conditions prevail in the masing OH and H_2O regions.

In compact H II regions, H_2O masing occurs at higher densities than OH masing (see ref. 12). The H_2O masers are necessarily located closer to the exciting source. If these excitation conditions apply to the situation described here of foreground molecular clouds, then H_2O inversion occurs only in the cores of clouds, whereas OH can be inverted over much large regions. This suggests that: (1) the linewidths of the H_2O maser lines be much smaller than those of the OH maser lines; (2) the H_2O masing regions are likely to be much smaller than

the OH masing regions, and are expected to vary on shorter timescales.

The outstanding H_2O maser features in the spectra of N3079 and N4258 do indeed vary on timescales of months (refs 5, 7; M. J. Claussen, personal communication). The spectra of most H_2O masing galaxies show distinct narrow features, sometimes superposed on some broader feature. Only the weakest OH masers have spectra breaking up into distinct features. However, the prominent narrow H_2O features have linewidths which are significantly larger than those of galactic masers.

Another difference between OH and H_2O maser lines is their velocity relative to the systemic velocity of the galaxy. In IC4553 the H I disk in absorption and the molecular disk in OH emission have the same centre velocity. This is also true for Mrk231 and NGC3690. However, the H_2O masers tend to have velocities away from the centroid velocity of the galaxies. This is strikingly apparent from the comparison of the OH absorption spectrum of NGC3079 and its H_2O spectrum[7]. The H_2O features in NGC3079 are blueshifted by 140 km s^{-1} relative to the OH centre velocity, but the features coincide in velocity with weak OH emission lines, which are superposed on the 1,667-MHz absorption line (B. E. Turner, personal communication). Similarly, the lines of NGC4258 are blueshifted 60 km s^{-1} when compared with the tentative OH absorption detection. NGC4945 has redshifted H_2O lines relative to the OH absorption velocity but these lines also coincide in velocity with a 1,612-MHz OH emission feature. M82 has one blueshifted H_2O feature, which again coincides in velocity with a 1,667-MHz OH emission feature, whereas another feature lies far to the red side of the OH absorption.

The prominent H_2O emission features originate possibly in dense (shocked) pockets of molecular gas with relatively high gains and having high relative velocities. In contrast, the OH emission may originate in more extended regions. Most of the galaxies in Table 2 have been searched for both OH and H_2O, but only in M82, NGC4945 and NGC3079 has emission been seen at both frequencies and at identical velocities.

Properties of masing galaxies

Two of the prime characteristics of the sample of masing galaxies, the presence of a strong nuclear radio continuum source and the infrared flux, are likely to be related[44]. Peculiar and interacting spirals have relatively high continuum-flux densities as well as extended nuclear sources[24,36]. Most of this radio emission can be explained in terms of starburst models[45]. However, it is not clear whether these nuclei have a Seyfert or a starburst nature, since a low ionization or Seyfert spectrum can hide an underlying H II region spectrum completely. The dust can effectively hide from sight the H II regions associated with the starbursts, which in turn may be responsible for the radio continuum sources. Possibly starburst nuclei and Seyfert nuclei are different stages of evolution of objects of one class[46].

The infrared properties of galaxies are still being elucidated, but it seems that double, interacting or merging galaxies are prominent among infrared galaxies[47–49]. Of the sample of masing galaxies, most are strong infrared sources and a few are known to be interacting or merging systems (NGC3690, IC4553, NGC520). It is likely, however, that most of these galaxies have experienced recent bursts of star formation and that the origin of the megamaser phenomenon can be traced to the coexistence of a radio continuum source, an ultraviolet radiation field to be converted into an infrared radiation field by the dust and remnant molecular material.

The detection rates of extragalactic masers have been very low. Four of the OH masers have been detected during surveys of 240 predominantly late-type spiral galaxies with radio continuum (W.A.B. *et al.*, in preparation). Recent searches for H_2O emission in 65 spirals produced four new cases[5–7]. These detection rates of 2–6% have been affected by: (1) a low filling factor for the proper type of molecular clouds (this factor is likely to be larger for the OH gas than for the denser H_2O cloudlets); (2) a relatively short lifetime of masing clouds compared with the lifetime of the continuum and infrared sources; (3) the relative detectability of signals at OH and H_2O; (4) the composition of the sample. The slightly higher probability of detecting H_2O masers could be caused by tighter selection criteria for the sample or by the fact that the gains for some H_2O maser features are higher, leading to better detectable features.

Conclusions

Maser activity in other galaxies is a newly discovered phenomenon and only a small number of cases have been found. Some of the characteristics of the OH and H_2O megamasers can be explained with a model involving unsaturated maser amplification of radio continuum structures (compact or extended) by foreground molecular material. The highest probability for a galaxy to produce observable maser emission is to have a nearly edge-on molecular disk with an embedded radio source and a proper pumping mechanism for the molecules. Most masing galaxies fulfill these requirements.

The nuclear spectra of the prominent masing galaxies have been classified as H II region or Seyfert types. A scenario for masing sources would then involve some sort of nuclear activity (with a burst of star formation or a Seyfert engine), which provides the radio source and an ultraviolet flux. The ultraviolet flux is downgraded to infrared by the surrounding dust. The infrared radiation is used to pump the foreground molecular gas, which in turn gives the maser emission. The starburst activity in several galaxies has probably been triggered by a merger or a galaxy/galaxy interaction in the recent past. All these nuclei could belong to one class, but have different amounts of dust and are at different stages of evolution.

The properties of the OH and H_2O maser lines are sufficiently different to suggest a difference in the excitation of the two molecules. Although they both may amplify the background continuum, the OH masing regions are probably more extended, whereas the prominent H_2O maser features are likely to originate in smaller cloudlets, either falling into the nucleus or flying out. These smaller pockets have a relatively higher gain (more saturated) than the surrounding (unsaturated) material, which results in an H_2O spectrum with narrow lines superposed on broader features.

The observed infrared flux for the masing galaxies seems to be sufficient to pump the molecular gas. However, for the OH masing galaxies, the infrared photon-to-line photon conversion efficiency can be only a few per cent, whereas for the H_2O masers this must be 50–100%. Possibly the bulk of the H_2O maser emission is due to saturated components. An approximately linear relationship between maser and infrared luminosity can be seen for the OH and H_2O masers. Apparently each type runs at its own approximately constant efficiency It is of interest to speculate what this diagram tells us about other galaxies to be detected in OH or H_2O At present H_2O features coincide with weak OH features in three galaxies (M82, NGC3079, and NGC4935). Except for these galaxies, OH and H_2O emission seem to be mutually exclusive.

The similarities and differences between OH and H_2O masers are important for determining the physical conditions of the masing material and provide valuable insight into the nature of these active galactic nuclei. Extragalactic megamasers seem to represent a new form of astronomical 'image processing' Unlike gravitational lensing, the processing is provided by diffuse clouds of interstellar molecules.

I thank Aubrey Haschick for discussions, Joan Schmelz for assistance with the observations, and Mike Davis for critical reading of the manuscript. Sources of acidification in Central Europe estimated from elemental budgets in small basins

Tomas Paces*

Geological Survey of Prague, Malostranske nam. 19, 118 21 Praha 1, Czechoslovakia

Long-term increase in acidification of water and soils in the Elbe river basin is caused mainly by the deposition of dry SO_2 and the application of industrial fertilizers. The direct input of hydrogen ions by acid rain is less significant. The budgets of elements and protons indicate natural and anthropogenic processes that acidify and buffer our environment.

CENTRAL Europe is a region seriously damaged by acid industrial emissions, as demonstrated by increased rates of corrosion[1,2], deterioration in forest productivity[3,4] and release of elements such as aluminium[5] and heavy metals[6] in water. A large-scale application of industrial fertilizers causes acidification of arable land and eutrophication of surface water[7,8]. Central Europe receives one of the highest inputs of sulphur from the atmosphere[9]; the runoff of anions of strong acids in surface water has increased while the runoff of weak acids, represented by alkalinity of stream water, has decreased in the past century[10]. The data in Table 1 present convincing evidence, independent of uncertain historical measurements of *p*H, that acidification has occurred. It may be related to acid rain[11], deposition of dry gaseous SO_2 and NO_x from the atmosphere on plants and soils[12], intensive application of industrial fertilizers[13,14] and depletion of organic matter from topsoil. These processes are of anthropogenic origin and affect the biogeochemical cycles and mass balances of naturally occurring chemical elements.

To collect quantitative data on the environmental changes and their rates, I have evaluated and compared mass budgets of H^+, Na, K, L, Mg, Ca, Fe, Al, Si, N-NH_4^+, N-NO_3^-, C-HCO_3^-, Cl, S and P in small hydrologically and geologically well-defined drainage basins in the watershed of the Elbe river (Fig. 1). Four representative basins considered here have similar bedrock, soil and climate conditions but differ in mean slopes and anthropogenic impacts. Comparison of their elemental budgets will help to elucidate the mechanisms that affect the fluxes of elements and cause acidification of soil and water. The data are used to calculate weathering and erosion rates influenced by acid emissions and agricultural practice. The elemental budgets in basins affected by industry and agriculture serve as background data for a comparison with representative basins in other regions.

* Present address: Department of Land Improvement and Drainage, Royal Institute of Technology, S-100 44 Stockholm, Sweden.

Regional characteristics

Representative basins shown in Fig. 1 are located on highlands composed of gneisses with interlayers of quartzites; the bedrock primarily contains oligoclase, quartz and biotite with <5% muscovite, orthoclase and sillimanite Gneisses are covered by colluvium with well-developed soil profiles to a depth of 120 cm. The soils are typical brown-to-acid brown earths (Food and Agricultural Organization classification: Eutric Cambisol to Distric Cambisol gleyic). Elevation, mean slopes of terrain and major hydrological characteristics of the basins are summarized in Table 2. The mean annual temperature varies from 5 to 7 °C. Two of the basins, X-0 and X-8, are covered with coniferous forest consisting mainly of spruce. The coniferous part of the

HCO_3^-	360	252	−4.3

forest in basin X-14 died several years before our observations started in 1975, but ~30% of the basin is still covered with deciduous trees and bushes, mainly oaks and beeches. Wheat, rye, barley, oats, maize, potatoes, clover, grass, flax and mustard seeds are rotated crops grown in basin X-7. These fields are intensively fertilized with industrial fertilizers and smaller amounts of organic matter, whereas the forested basins are not fertilized.

Basins X-0, X-7 and X-8 are located in a rural region of the Trnavka river basin (Pacov, Czechoslovakia) without local sources of industrial pollution. The mean concentration of SO_2 in air calculated from daily measurements in 1983 was 8.3 $\mu g\ m^{-3}$, with a monthly variation coefficient of 37%. The concentration of NO_x was 11.2 $\mu g\ m^{-3}$, with a variation coefficient of 31% (ref. 15). The forested basin X-14 is on the eastern slope of the Ertzgebirge Mountains facing the industrial region of the city of Most with open-pit coal mines and power plants in which local coal with a high sulphur content is burned. The 3-yr mean concentration of SO_2 in air was 112 $\mu g\ m^{-3}$ with a variation of 52%, whereas the mean concentration of NO_x was 33 $\mu g\ m^{-3}$ with a summer and winter half-year variation coefficient of 38% (ref. 15).

I have grouped the representative basins in three pairs to illustrate the influence of various factors on their elemental budgets, the first basin of each pair serving as a reference, the second showing the influence of a given factor. The effect of mean slope in forest is demonstrated by the pair X-0 and X-8; both basins are located in the rural region and have slopes of 3.8 and 13%, respectively. The effect of acid industrial emissions in forests is shown by the pair X-8 and X-14 and the effect of modern agriculture by the pair X-0 and X-7. The comparison is based on annual arithmetic means for observation period 1976–82 (7 hydrological years) in basins X-0, X-8 and X-7 and for observation period 1978–82 (5 hydrological years) in basin X-14.

Input and output mechanisms

Atmospheric precipitations were measured at 10 stations by international meteorological methods. Samples for chemical analysis were collected 1.3 m above ground, rainwater through glass funnels in polyethylene bottles and snow directly in polyethylene buckets. The diameters of the collectors were 25 and 30 cm. The containers were exposed only during individual precipitation episodes to determine the composition of wet precipitation. A similar set of collectors was exposed permanently for approximate estimation of total deposition. Samples were stored in a refrigerator immediately after each precipitation epsiode and analysed once a month. They were not filtered or acidified before chemical analaysis[16,17].

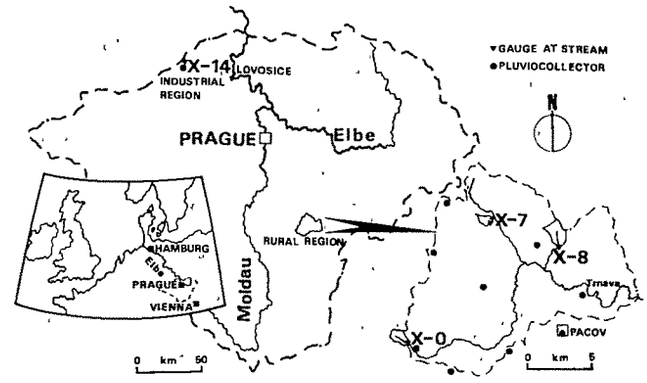

Fig. 1 Location of representative basins in the watershed of the Elbe river. Numbers and symbols correspond to the system established by the Geological Survey of Prague.

Runoff water from the basins was measured continuously at gauge stations in stream channels. The subsurface discharge was found to be negligible by a detailed hydrological and geophysical investigation[18]. Samples for chemical analysis were collected once a month, but more frequently during extreme hydrological episodes such as spring thaw and summer rainstorms. This frequency of sampling was found to be satisfactory because the variation in electric conductivity of the set of collected samples was not statistically different from the variation in the conductivity measured in runoff every day. The samples were filtered through a 0.45-μm filter within 1 day of collection. In the field, water was filtered through a 0.1-μm filter for determination of dissolved Al. This method of sampling gives reproducible results because all sampled streams are very low in concentration of organic matter[30]. Blank samples of deionized water were prepared and analysed by the same methods to check for possible contamination during sampling and analytical procedures. The *p*H of water was measured potentiometrically in the field; the flux of dissolved elements in water was calculated by multiplying the discharge of water between two sampling intervals and the arithmetic mean of the concentrations.

Biological output from the forested basins was determined from detailed records of biomass production in individual plots of the forests and chemical analyses of randomly selected trees. Mean annual production of biomass was multiplied by the mean concentration of elements in fresh wood to estimate the output of biologically fixed elements in basins X-0 and X-8. No data on biological fixation are available for basin X-14 because of

The values are mean annual fluxes in kg ha^{-1} yr^{-1}; means represent 7 hydrological years in basins X-0, X-8 and X-7 and 5 hydrological years in basin X-14.

* The high atmospheric input of aqueous Al probably results from the hydrolysis of dust in the atmosphere. This hydrolysis buffers the pH of rain before it falls in the basins. This is reflected by the lower values of the precipitation flux of hydrogen ions, P_{H^+}.

dieback of 70% of the tree population. I estimate the biological fixation in basin X-14 to be about one-third of the fixation in basin X-8. The data on biological fixation represent only the long-term output resulting from lumbering. I did not obtain reliable data on the net accumulation of biomass in the basins, therefore, I assume that the biomass remaining in the basins is recycled and that the net annual accumulation is approximately equal to the annual output by lumbering.

Anthropogenic input in field basin X-7 includes fertilization and sowing. The quantities of the applied fertilizers and seeds were recorded and samples collected. The applied quantity multiplied by mean concentrations of elements in fertilizers and seeds was summed over individual hydrological years to represent annual anthropogenic input. Biological output from basin X-7 was determined by recording the harvested amounts of crops and analysing samples from individual fields. Grains and straw, tubers and haulm were analysed separately. Water, rocks and soils were analysed in our laboratory by atomic absorption spectroscopy for Na, K, Mg, Ca and Fe and atomic absorption flameless spectroscopy for Al and photometry for Si. NH_4^+ and Cl^- ions were determined by ion-sensitive electrodes and NO_3^- and SO_4^{2-} by standard methods of wet analysis[19]. Organic samples were analysed by a specialized agricultural laboratory (District Agricultural Testing and Control Station, Brno). Precision of the analyses of water was tested against international standards[20] with good results. The precision of the chemical analyses of organic samples and fertilizers was not reported. The accuracy of the analyses, however, is probably greater than my determination of the mass of organic matter entering and leaving the basins. The accuracy is 7% for precipitation and runoff water analyses and 30% for the anthropogenic input and biological output measurements.

Budgets of elements

The fluxes of elements resulting from wet precipitation and runoff from the basins are summarized in Table 3, anthropogenic input and biological output are given in Table 4.

Inputs, outputs and accumulation affected by acidification but which cannot be easily measured in field include: (1) input of elements by total (that is, chemical plus mechanical) weathering of bedrock; (2) output by chemical erosion, (3) output by mechanical erosion; (4) accumulation of sulphur in regolith; and (5) production and consumption of hydrogen ions (proton balance). These fluxes are estimated with a help of various mass-balance models.

Rate of total weathering of bedrock, rates of chemical and mechanical erosion and related inputs and outputs of elements are calculated using a steady-state model of weathering[10,21] (assuming that Na and Si in regolith are in a steady state). The annual acccumulation or depletion of these elements in weathered zone is negligible compared with their annual inputs and outputs so that the amounts in regolith of the basins are approximately constant with time. In such a case, the input of an element i resulting from total weathering of bedrock, W_i (kg per hectare (ha) per yr), can be calculated from a steady-state mass-balance equation

$$W_i = -(P_i - R_i + A_i - B_i - M_i) \quad (1)$$

where P_i is input of chemical element i by atmospheric precipitation, R_i is output of element i by runoff from drainage basin, A_i is anthropogenic input of element i, B_i is output of biologically fixed element i and M_i is output of element i by mechanical erosion of weathered material.

Two equations (1) written for i = Na and Si contain four unknown values: W_{Na}, W_{Si}, M_{Na} and M_{Si}. These values are related to a rate of total weathering of bedrock, W_{rock}, and to mechanical erosion of regolith, M_{rglth}, by the following equations

$$W_i = W_{rock}\, x_{i,rock} \quad (2)$$

$$M_i = M_{rglth}\, x_{i,rglth} \quad (3)$$

Values are mean annual fluxes, kg ha^{-1} yr^{-1}.

where $x_{i,rock}$ and $x_{i,rglth}$ are dimensionless concentrations ($g\ g^{-1}$) of element i in bedrock and its regolith respectively. Including W_{rock} and M_{rglth}, there are six unknown and six independent equations (1), (2) and (3) written for i = Na and Si. This system of equations is solved to yield the rate of mechanical erosion of regolith

$$M_{rglth} = \{[(P_{Na} - R_{Na} + A_{Na} - B_{Na})/x_{Na,rock}] - [(P_{Si} - R_{Si} + A_{Si} - B_{Si})/x_{Si,rock}]\}/[(x_{Na,rglth}/x_{Na,rock}) - (x_{Si,rglth}/x_{Si,rock})] \quad (4)$$

and mechanical erosion of any element, M_i, according to equation (3). Substituting the calculated values of mechanical erosion of Na and Si, M_{Na} and M_{Si} in equation (1), we obtain the rate of the input of the elements resulting from total weathering of bedrock, W_{Na} and W_{Si}. Finally, either of the last-mentioned values substituted in equation (2) yields the rate of total weathering of bedrock, W_{rock} (Table 5).

The rate of chemical erosion of weathered bedrock, C_{rock}, is calculated from equation (5)

$$C_{rock} = -\sum_i (P_i - R_i + A_i - B_i)\ m_{oxide}/n.m_i \quad (5)$$

where $\sum$ includes all elements composing bedrock except O, m_{oxide} is the relative molecular mass of the respective oxide, n is the stoichiometric coefficient of the cation in the oxide (for example, $n = 2$ for Na_2O) and m_i is atomic mass of the cation i. The flux resulting from chemical erosion of weathered bedrock includes direct dissolution of bedrock (that is, chemical weathering) and desorption of exchangeable ions from soil. Mechanical erosion of bedrock is defined by equation

$$M_{rock} = W_{rock} - C_{rock} \quad (6)$$

Note that the rate of mechanical erosion of bedrock, M_{rock}, is different from the mechanical erosion of regolith, M_{rglth}, calculated from equation (4), because weathered material contains components not only derived from bedrock but also others, such as water molecules and organic matter. The calculated rates of chemical and mechanical erosion of gneisses in the basins examined here are summarized in Table 5. The effect of various factors on weathering and erosion are expressed by ratios of the characteristic rates for the individual basins

Accumulation of S in regolith of the basins, which is an important process of environmental acidification, is expressed by a mass-balance equation

$$P_S - R_S + A_S - B_S + W_S + D_S + G_S = \sum_S \quad (7)$$

where $\sum_S$ is accumulation of S in kg ha^{-1} yr^{-1} (this value contains all the uncertainties and errors inherent in the values of fluxes in equation (7)), fluxes P_S, R_S, A_S, B_S were measured in the field, W_S was calculated from the weathering rate of bedrock, W_{rock}, in Table 5 and mean concentration of S in bedrock from equation (2); D_S is the atmospheric input of S during dry periods calculated as a difference between the values measured by permanently exposed collectors and by collectors exposed only to wet precipitations; G_S is deposition of dry S-SO_2 from the atmosphere A small portion of D_S may result from the deposition of SO_2 in the permanently exposed collectors, but this is negligible compared with the deposition of SO_2 on vegetation and soil (G_S)

The deposition of dry SO_2 was estimated from the mean deposition velocity and the mean concentration of SO_2 in the local atmosphere. Deposition velocity was calculated from published estimates for snow cover and for dry and wet periods during which stomata of trees were opened and closed[22]. The deposition velocity in forested basins X-0 and X-8 of the rural region is 5.8 mm s^{-1} The mean concentration of SO_2 is 8.3 μg m^{-3} and the corresponding deposition rate of dry SO_2 is 7 6 kg ha^{-1} yr^{-1} of S. I do not have adequate data on the deposition velocity on fields in basin X-7, but assume that it is the same as the forest basins of the rural region The deposition velocity may be slightly lower in basin X-14 because of the longer duration of snow cover at the higher altitude and the thin biological cover. The velocity is estimated to be 5 mm s^{-1} and the mean concentration of SO_2 112 μg m^{-3}, with the corresponding flux 88.6 kg ha^{-1} yr^{-1} of S (only one digit of the value is significant). The fluxes of S and calculated accumulation according to equation (7) are given in Table 6 I find that the accumulation is approximately the same in all the basins despite the large difference in the concentration of SO_2 in the air of the rural and industrial regions.

Units, mmol $m^{-2}\ yr^{-1}$ of H^+; * uncertain values (see text)

The process of acidification is best represented by the proton balance of all fluxes and reactions which involve an exchange of H^+ such as acid rain, ion exchange, hydrolysis of minerals, biological fixation of ions, oxidation of pyrite and SO_2 in regolith and nitrification[23-25] The inputs, outputs, production and consumption of H^+ in mmol $m^{-2}\ yr^{-1}$ calculated from the measured and estimated fluxes of elements in the representative basins are shown in Table 7. The most important source of H^+ is not acid rain but the deposition and subsequent oxidation of dry SO_2, transformation of nitrogen species and biological fixation of cations. The most important sink of H^+ is hydrolysis of rock-forming minerals and ion exchange in soil. Taking into account all the known processes that involve the exchange of protons, there is an 'excess' production of H^+ in all the representative basins (Table 7). This 'excess' production is not an artefact of electrical imbalance of chemical analyses (Table 7); it must be consumed in the soil by processes that are not apparent in the considered fluxes, probably the protonation of organic active groups in soils, specific adsorption of H^+ on negative surfaces of clay minerals and sesquioxides and hydrolysis of dead organic matter. These processes, together with the depletion of exchangeable cations, gradually exhaust the buffering capacity of local soils.

Discussion

Acidification of soil and water is a dynamic process which depends on fluxes of acidifying chemicals and on geochemical and biochemical reactions involving an exchange of protons in the whole ecosystem. Harmful effects such as the die-back of trees occur when the excess production of protons lasts long enough to exhaust the buffering capacity of soils. The causes of acidification in Central Europe are natural and anthropogenic, the major natural process being the biological fixation of cations and the major anthropogenic processes the emissions of SO_2 and the application of industrial fertilizers. The direct input of H^+ by acid rain is of importance in the forests of rural region while in the field basin it is secondary to biological acidification and in the industrial region it is less important than the input of H^+ resulting from deposition and oxidation of dry SO_2. Geochemical processes such as oxidation of sulphide minerals and precipitation of ferric hydroxide are not important.

The rural region with a relatively low concentration of SO_2 in air and the industrial region with a very high concentration of SO_2 are 160 km apart. The average concentration gradient of SO_2 in air is very steep, 0.65 μg m^{-3} km^{-1}. It corresponds to the increase in H^+ production by the oxidation of adsorbed SO_2, equal to 3.2 mmol $m^{-2}\ yr^{-1}\ km^{-1}$ from the point-source of emissions. This is in contrast to a very small increase in the input of H^+ resulting from acid rain which is only ~0.06 mmol $m^{-2}\ yr^{-1}\ km^{-1}$. This gradient in the input of SO_2 correlates with the observed die-back of coniferous trees and the acceleration of weathering and erosion accompanied by the increased output of nutrients. The total weathering rate of gneisses increases by a factor of 2.1, chemical erosion by 2.9 and mechanical erosion by 1.9 in forest in the industrial region. Part of the increase is caused by the steeper slope of basin X-14 and by higher precipitation and discharge rates. The runoff of all the elements (except Fe) increases (Table 3) The decrease in pH of runoff from basin X-14 causes the alkalinity of water to fall below the detection limit so that water in the basin loses its carbonate buffering capacity. At the same time, alumina starts to behave as a buffer and consumes protons at the rate of 13 mmol $m^{-2}\ yr^{-1}$ (Table 7). This leads to a large increase in the runoff of dissolved Al from 0.11 kg $ha^{-1}\ yr^{-1}$ in basin X-8 to 3.2 kg $ha^{-1}\ yr^{-1}$ in basin X-14 (Table 3). Acidification in the forest of the industrial region is accompanied by a large increase in runoff of nitrates from 0.58 kg $ha^{-1}\ yr^{-1}$ of N in basin X-8 to 12 kg $ha^{-1}\ yr^{-1}$ in basin X-14. The increased flux of nitrates does not originate from polluted air because the mean annual concentration of NO_x in air increases three times (from 11 to 33 μg m^{-3}) while the output of nitrates increases >20 times. Therefore, the increased output reflects the decreasing denitrification capacity of damaged forest in basin X-14. This agrees well with the increased runoff of nitrates from a similar forest basin in New Hampshire which was clear cut experimentally[26].

The consumption of H^+ by ion exchange in soil and hydrolysis of bedrock is not fast enough to neutralize the acidifying inputs

in any of the forest basins described here. The excess production of 80 and 74 mmol m^{-2} yr^{-1} in the forests of basins X-0 and X-8 does not seem to have a damaging effect on trees; it does not lower runoff *p*H and does not increase the output of dissolved Al and nitrates. But the buffering capacity of local soils may soon be exhausted. It is possible that the excess hydrogen ions protonate organic active groups and that they are specifically adsorbed on clay minerals and sesquioxides, causing a reversal in surface charge of some soil particles[27]. If the specific adsorption of excess H^+ is irreversible, then the exhaustion of the buffering capacity of soils and the changes in the surface charge of soil particles may have a sudden negative effect on the productivity of the forest.

The studies reported here support the suggestion[28] that modern agriculture contributes to acidification. The major acidifying mechanism is the application of fertilizers containing the weak base NH_3 and strong acids H_2SO_4 and HNO_3. Agricultural practices in basin X-7 speed up the total weathering of gneiss by factor of four, but most of the weathered bedrock is removed by mechanical rather than chemical erosion. The increased runoff of dissolved substances is caused by fertilization; ~89% Cl, 83% S and 17% N introduced in fertilizers are leached out. On the other hand, cations are retained by plants contributing to acidification of soil and water. The *p*H of runoff from field basin X-7 decreases by ~1 *p*H unit to *p*H 6.15, compared with the runoff from its reference basin X-0. The decrease in *p*H is not enough to mobilize Al, whose flux remains low. The excess production of protons in basin X-7 is 175 mmol m^{-2} yr^{-1}, 95 mmol m^{-2} yr^{-1} more than in the reference basin X-0. Although the uncertainty in this value is large because of the less precise values of biological fixation, the general acidifying trend in the field basin is clear.

The observed differences in the fluxes between the basins representing the agricultural and industrial influence on cycling of elements are not affected greatly by different slopes of terrain. Although the ratio of slopes X-8/X-0 is 3.4, the ratio of chemical erosion is only 1.7. The ratio of slopes X-14/X-7 is 3.7 and the ratio of chemical erosion 2.0, but basin X-14 receives more atmospheric precipitations and the runoff is faster. The hydrological factor increases input and output rates of elements including H^+ and is therefore an important factor of acidification. The fast rate of flushing through basin X-14 may be the cause of the relatively small accumulation of S in spite of an extremely high input of dry SO_2. The similar accumulation rate of S in the same type of soils in the rural and industrial regions indicates that the properties of soils may be important in S accumulation.

The measured and calculated fluxes of chemical elements in the representative basins indicate that observed long-term trends in the flux of dissolved elements from the Elbe river in central Europe are caused mainly by industrial emissions and intensive application of inorganic fertilizers. The runoff from central Europe is still effectively buffered because the mean *p*H of the Elbe river is 7.1. Locally, however, the *p*H of runoff drops below the capacity of CO_2/HCO_3 buffer; here, Al is mobilized and its runoff increased. In the areas with strong input of dry SO_2 and intensive application of inorganic fertilizers, the soils are acidified even if the acidification of runoff is small. Acidification can gradually exhaust the buffering capacity of soils and change surface charge on soil particles. At an 'inflection' point, by analogy with acid–base titration, it may lead to a sudden drop in biological productivity and die-back of coniferous trees. This inflection point is not yet defined; its existence is suggested by the fact that the acidification of soils in Central Europe has proceeded for decades whereas the die-back of forests is a relatively fast phenomenon which takes only a few years.

The data described here are too preliminary to separate quantitatively the distribution of H^+ ions that are generated in excess by natural and anthropogenic acidification. Some of the ions are consumed by ion exchange causing a depletion of the exchangeable cations in soil and loss of nutrients such as Ca^{2+} and Mg^{2+}. Some H^+ ions are used up by hydrolysis of rock-forming minerals; this process increases the rate of chemical weathering and may be ecologically beneficial because it releases nutrient cations from bedrock. Some of the produced H^+ ions are consumed by organic acid groups and may be adsorbed specifically on negative surfaces of clay minerals and sesquioxides. This may reverse the charge of some active surface sites and negatively affect properties of soils. Further research is needed to clarify the distribution of excess H^+ and the mechanisms of their consumption within water–soil–rock systems.

This paper was written at the Geological Institute of the Louis Pasteur University, Strasbourg. I thank Professor Y. Tardy for his support of this research. The data on precipitations were obtained by the research team of Dr B. Moldan and data on runoff, anthropogenic inputs and biological outputs were collected by Mrs E. Pacesova, all of the Geological Survey of Prague. I also thank Dr C. A. J. Appelo (Institute of Earth Sciences, Free University, Amsterdam), Dr N. van Breemen (Department of Soil Science & Geology, Agricultural University, Wageningen) and Dr H. M. Seip (Central Institute for Industrial Research, Oslo) for constructive criticism and valuable advice.

The three-dimensional structure of calmodulin has been determined crystallographically at 3.0 Å resolution. The molecule consists of two globular lobes connected by a long exposed α-helix. Each lobe binds two calcium ions through helix–loop–helix domains similar to those of other calcium-binding proteins. The long helix between the lobes may be involved in interactions of calmodulin with drugs and various proteins.

CALMODULIN is one member of a family of low relative molecular mass acidic calcium-binding proteins[1]. Many of these proteins, such as parvalbumin, troponin-C, intestinal calcium-binding protein and S-100, are found only in vertebrates and, even in these animals, are restricted to a small number of tissues or cells. In addition, the function, when known, is specific and limited to one metabolic process or pathway. Calmodulin is the unique member of this protein class, as it is present in all eukaryotic cells and serves many functions[2,3]. This Ca receptor is a single 148-amino-acid polypeptide chain containing four Ca-binding sites and is highly conserved throughout evolution[3–6].

Although calmodulin exhibits significant α-helicity even in the absence of Ca, binding of this ion results in an increase in the α-helical content[7–10]. It is this Ca-induced conformational change that allows calmodulin to interact with enzymes, peptides and pharmacological agents such as the phenothiazines[2,3]. A major question is how the protein can interact specifically with so many different molecules. It is possible that the regulation of different enzymes by calmodulin is partially a function of the number of Ca ions bound. However, controversy exists regarding the order in which the four sites are filled and the discrete structural changes that accompany Ca binding.

Here we describe the structure of calmodulin at 3.0 Å resolution (Fig. 1). Calmodulin represents the fourth member of the Ca-binding protein family to be characterized crystallographically. (The other three include parvalbumin[11], intestinal Ca-binding protein[12] and troponin-C[13,14].) However, it is the first ubiquitous intracellular Ca receptor to be subjected to such scrutiny and represents the first Ca-binding protein where the gene[6,15] and protein structure can be be compared directly.

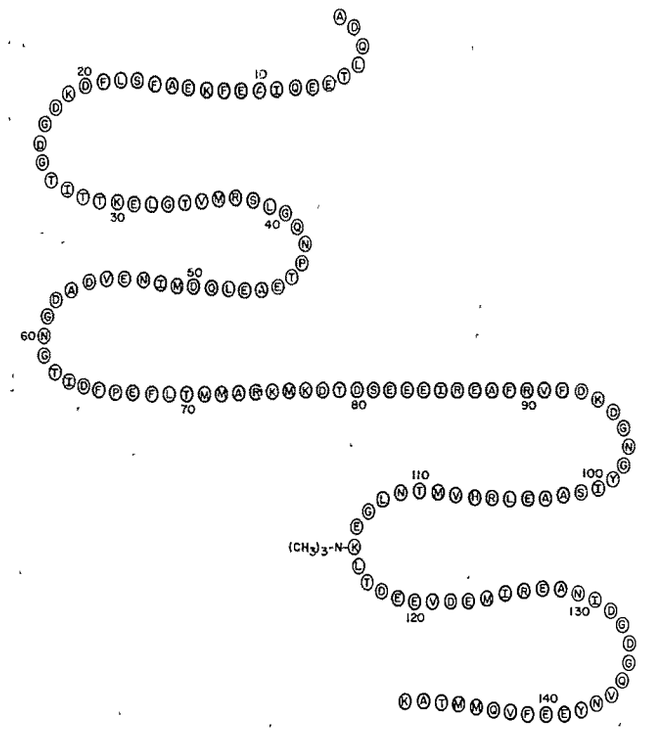

Fig. 1 Amino-acid sequence of calmodulin The sequence is arranged to show schematically the topology of the molecule. Bold circles represent residues in α-helices.

Structure determination

Calmodulin from rat testes was isolated and purified as described previously[7]. The crystallization technique was the same as described by Cook and Sack[16]; all crystals were obtained from solutions of 2-methyl-2,4-pentanediol at *p*H 5.6. The crystals belong to triclinic space group P1 with unit cell dimensions $a = 29.84$ Å, $b = 53.72$ Å, $c = 24.94$ Å, $\alpha = 93.3°$, $\beta = 97.45°$ and $\gamma = 88.77°$; there is one molecule per unit cell.

Two heavy-atom derivatives, lead acetate and potassium platinum tetrachloride, were used in the solution of the structure by the multiple isomorphous replacement method. They were obtained by soaking crystals in 75% (v/v) 2-methyl-2,4-pentanediol that contained 0.05 M cacodylate (*p*H 5.6) and the heavy-atom reagent. Many attempts to replace the Ca ions by lanthanide ions were unsuccessful.

Data for native and derivative crystals were collected with a Picker FACS-1 diffractometer at room temperature using an omega step-scan and nickel-filtered CuKα-radiation. Friedel mates were measured during data collection at negative 2θ values in groups of 10 reflections, alternating with their counterparts. Standard reflections were measured periodically and were used to correct for decomposition. Absorption corrections were applied according to the method of North *et al.*[17].

The heavy-atom positions were determined by a combination of three-dimensional isomorphous difference Patterson and difference Fourier maps. Phases for the difference Fourier maps were calculated by the method of Blow and Crick[18]. Cross difference Fourier maps were used to bring the Pb and Pt coordinates to a common origin and, in conjunction with the use of anomalous data, to establish the correct enantiomeric arrangement of heavy atoms. The heavy-atom parameters were refined by the origin-removed Patterson method of Terwilliger and Eisenberg[19]. This procedure is based on the Patterson-function correlation method of Rossmann[20], except that the origins of the Patterson function are now removed from this correlation and centric and acentric reflections are treated separately. The final model for the Pb derivative consists of seven sites; two Pb ions substitute for Ca. The Pt derivative contains three sites. Various statistics for the heavy-atom derivatives are summarized in Table 1. The protein phases and the figures-of-merit were calculated by the method of Blow and Crick[18].

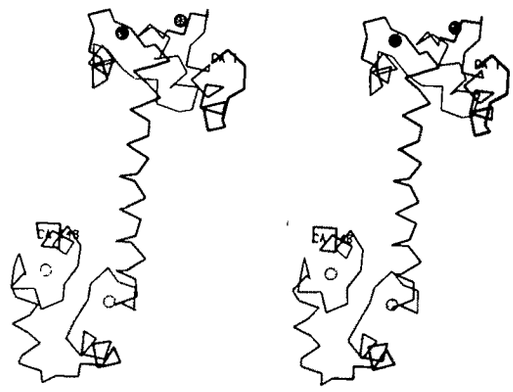

Fig. 2 Stereo drawing of the α-C backbone of calmodulin The four Ca ions are represented by dotted circles.

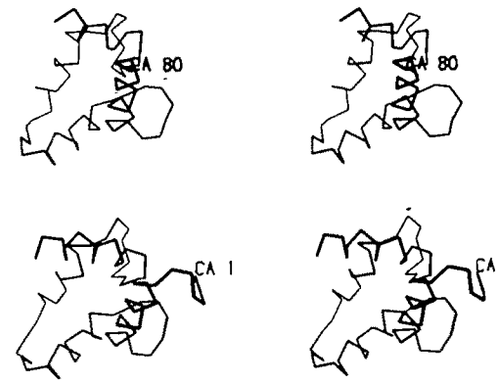

Fig. 3 Stereo drawing of the two pairs of Ca-binding domains. The molecule has been split between residues 79 and 80 and the two halves shown in approximately the same orientation

Contributions from the anomalous differences were included in the phase calculations. The overall figure-of-merit is 0.71 for the complete data set to 3 Å resolution.

An electron density map at 3 Å resolution was computed from the 'best phases' with figure-of-merit weighting factors[18]. This map clearly showed the molecular boundary and most of the secondary structural features, but the polypeptide chain could not be followed completely without ambiguities. Sequence alignment was further complicated by the high degree of internal sequence homology A modified electron density map was obtained by using a tentative chain tracing to assign a molecular boundary, flattening the solvent regions outside the molecular boundary and removing negative electron density values in the molecular boundary. This modified map was back-transformed to produce calculated phases, which were then combined with the multiple isomorphous replacement phases using the method of Bricogne[21]. A map calculated with the resultant phases resolved most of the ambiguities in chain tracing, primarily resulting from better definition of side-chain density; α-C atom positions for most of the residues were assigned from this map. A partial model was traced without residues 1–7, 75–80 and 129–148 These regions either had weak density or contained breaks in the density. The partial model was built and regularized using the computer graphics package FRODO[22]. Phases were calculated from this model and combined with the original multiple isomorphous replacement phases using the method of Bricogne[21]. The resultant map showed the protein density more clearly, allowing the model to be built completely. The four Ca positions were confirmed from a native anomalous difference Fourier map, calculated using the combined phases.

Structure description

A tracing of the α-C backbone of calmodulin is shown in Fig. 2. The molecule looks somewhat like a dumbbell with the two lobes connected by an eight-turn α-helix and no contacts between the two lobes. The length of the molecule is ~65 Å, with each lobe having approximate dimensions of 25 × 20 × 20 Å. The two Ca-binding domains in each lobe are related to each other by an approximate 2-fold axis. The two individual lobes can be brought into approximate register by a rotation of ~90° coupled with a translation. The two halves of the molecule are remarkably similar; the corresponding α-carbon positions can be superimposed with an average difference of ~1 Å (Fig. 3). The molecule contains seven helices, I–VII, consisting of residues 7–19, 29–39, 46–55, 65–92, 102–112, 119–128 and 138–148. The helix content is 63%, which is about the same as observed in troponin-C[13,14]. Calcium-binding domains 1 and 4 have a typical helix–loop–helix conformation and are similar to the two Ca-binding domains in parvalbumin[11] and to the III–IV domain in intestinal Ca-binding protein[12]. Domains 2 and 3 also display helix–loop–helix conformations, but are different from that found in parvalbumin and intestinal Ca-binding protein in that these two domains share helix IV. This long helix provides both the carboxy-terminal helix for domain 2 and the amino-terminal helix for domain 3. Helix IV is two to three times longer than any of the other helices in the molecule. Because most of helix IV is exposed to solvent and forms only a few contacts with the rest of the molecule, it is possible that this part of the molecule retains some helical structure in the absence of Ca.

The Ca-binding segments consist of residues 20–31, 56–67, 93–104 and 129–140. These four segments are similar to the two that are described in parvalbumin[11] and to the calcium-binding region III–IV in intestinal Ca-binding protein[12]. All of these contain 12 residues; the first 9 form the loop and the last 3 the beginning of the second helix in the helix–loop–helix domain. In all of these Ca-binding domains, the Ca ion is displaced from the centre of the loop towards the amino-terminal helix of the helix–loop–helix domain. The second helix of each domain orients the last residues of the Ca-binding segment so that they can participate in Ca coordination.

The molecule is stabilized by multiple interactions between the helices. In addition to these interactions, there is hydrogen bonding between adjacent Ca-binding loops in each half of the molecule. Residues 25–29 run antiparallel to residues 61–65 and these two stretches are joined by H bonds between Gly 25 and Asp 64 and between Ile 27 and Thr 62. In the second half of the molecule, the stretches 99–101 and 135–137 are also antiparallel and are joined by H bonds between Ile 100 and Val 136. Similar arrangements of the calcium-binding loops are found in parvalbumin and intestinal Ca-binding protein. Ca-binding domains in calmodulin are joined by linker segments composed of six residues; this compares with the linker segments of 8 residues in parvalbumin[11] and 10 in intestinal Ca-binding protein[12].

In each half of the molecule the two Ca ions are ~11.3 Å

Table 1 Statistics for the heavy-atom derivatives

	$Pb(C_2H_3O_2)_2$	K_2PtCl_4
Resolution (Å)	3 0	3.2
Merging R (%)	4 7	2.5
Heavy-atom concentration (mM)	0 7	0.2
Fractional change (%)	30	12
No. of heavy-atom sites	7	3
$F_H(\text{calc})/E$	2.7	1 5

$$\text{Merging } R = \frac{\sum ||F(h)| - |F(\bar{h})||}{\sum |F(h)| + |F(\bar{h})|}$$

$$\text{Fractional change} = \frac{\sum ||F(\text{PH})| - |F(\text{P})||}{\sum |F(\text{P})|}$$

where $F(P)$ and $F(PH)$ are observed structure factors for native protein and heavy-atom derivatives, respectively. $F_H(\text{calc})$ is the r m.s value for calculated structure factor contributions of heavy atoms. E is the r.m s. value for the lack-of-closure errors

apart and are coordinated to main-chain oxygen atoms and to oxygen atoms from the side chains of acidic residues. It is not clear at this stage of the analysis if there are any solvent molecules in the Ca coordination spheres. There is disagreement about the location of high- and low-affinity Ca-binding sites, but most recent studies using Ca binding and NMR seem to agree that sites 3 and 4 are the high-affinity sites[23-26]. In the Pb derivative, two of the Pb ions replace the Ca ions in domains 1 and 2. Therefore, our data are consistent with other evidence that sites 3 and 4 are the high-affinity sites.

Discussion

Calmodulin exhibits a high degree of sequence homology with parvalbumin and troponin-C[27,28], but homology with intestinal Ca-binding protein is restricted to the Ca-binding regions. Based on the structure of parvalbumin, Kretsinger and Barry[29] proposed a helix-loop-helix (or EF hand) conformation for the Ca-binding regions in troponin-C. An EF hand is a linear sequence of ~30 amino acids where two nearly perpendicular α-helices flank a 12-residue Ca-binding loop. Parvalbumin contains two such Ca-binding domains. Based on the structural features of these two domains, Tufty and Kretsinger[30] postulated that a stretch of 16 amino acids is essential for the formation of a Ca-binding EF hand. They applied this test sequence to a wide variety of proteins and generalized that all intracellular Ca-modulated proteins contain EF hands. The crystal structure determination of intestinal Ca-binding protein[12] and our results for calmodulin provide structural confirmation of this hypothesis. However, there are significant differences among the three structures, primarily in interhelical angles. A comparison of these angles is given in Table 2. The average interhelical angle in calmodulin is smaller than in parvalbumin and in intestinal Ca-binding protein. The angles in calmodulin are closest to 90°, whereas those in intestinal Ca-binding protein deviate most from 90°.

Table 2 Inter-helical angles in the Ca-binding domains

Calmodulin		Parvalbumin		Intestinal calcium-binding protein	
Helix pair	Angle (deg)	Helix pair	Angle (deg)	Helix pair	Angle (deg)
I-II	92	C-D	103	I-II	121
III-IV	96	E-F	102	III-IV	121
IV-V	97				
VI-VII	107				

The interhelical angles for parvalbumin and intestinal Ca-binding protein are taken from ref. 12.

Rat testis calmodulin contains two tyrosine residues at positions 99 and 138 that reside in the third and fourth Ca-binding domains, respectively[27]. Our studies reveal that these two residues occupy different environments. Tyr 99 is directed into the third Ca-binding loop and is fairly accessible to solvent. Tyr 138 points away from loop four into a hydrophobic pocket where it contacts Phe 89 in helix IV and Phe 141 in helix VII. Thus, although Tyr 99 forms contacts only with residues in domain 3, residues from both domains 3 and 4 interact with Tyr 138. The observed structure supports the earlier evidence that Tyr 138 occupies a hydrophobic environment[8,31-33]. The different environments of the two tyrosine residues could explain why an azido derivative of Tyr 99 can be crosslinked to many more calmodulin-binding proteins than the comparable derivative modified at Tyr 138 (ref. 34). Although Tyr 99 is in one of the Ca-binding loops, it cannot be essential for Ca binding as it is replaced in the spinach protein by phenylalanine and in the protozoan *Tetrahymena* protein by leucine[5].

Vertebrate calmodulins contain a trimethyllysine residue at position 115. Seamon[31] has suggested that this amino acid is exposed to solvent in the absence of Ca. The crystal structure reveals that trimethyllysine is in the region between helices V and VI and is directed towards the solvent with no obvious interactions with other residues in the molecule. Van Eldik *et al.*[35] have shown that trimethylation is not required for Ca-dependent interaction with phenothiazines. Putkey *et al.*[36] have reported that this post-translation modification also is not required for Ca binding, activation of several calmodulin-dependent enzymes or for Ca-induced conformational changes. These facts, together with the absence of a trimethyl group on Lys 115 in several invertebrate calmodulins[3,5], make it unlikely that this rare modification is mandatory for function.

One unusual aspect of the calmodulin structure is the long central helix (helix IV) connecting Ca-binding domains 2 and 3. This long helix seems to serve as the backbone of the protein with the two halves of the molecule attached on either end of the helix. Because this helix is shared by Ca-binding domains 2 and 3, it may have a role in the cooperative binding of Ca. Troponin-C has a similar long central helix that connects the two halves of the molecule; in the crystal structure of troponin-C, there are two Ca ions bound to the carboxy-terminal domain, whereas the cation-binding sites of the amino-terminal domain are Ca free. The amino-terminal portion of troponin-C seems to wrap around the first part of the central helix, it is possible that in a similar fashion the carboxy-terminal portion wraps around the second part of this helix when Ca is removed. Thus, the central helix in troponin-C and calmodulin may be buried in the absence of Ca and exposed when the ion is bound, which would be consistent with proteolysis studies of calmodulin. The greatest sensitivity of calmodulin to trypsin occurs among the residues in this central helix. In the presence of Ca, limited proteolysis results in one cleavage in the centre of this helix that produces two fragments 1-77 and 78-148 (refs 25, 37-39). However, in the absence of Ca the fragments produced are 1-106, 1-90 and 107-148 (refs 25, 37-39). This suggests that Ca binding exposes the residues in helix IV to proteolytic attack.

Several lines of evidence suggest that the residues in helix IV have an important role in the interaction of calmodulin with receptor proteins and drugs. The chemical modification studies of Walsh and Stevens[40] showed that carboxymethylation of methionine residues 71, 72 and 76 prevents the productive interaction of calmodulin with cyclic phosphodiesterase. Also, Newton *et al.*[41] have covalently attached a phenothiazine to the Ca^{2+}/calmodulin complex. The primary site of attachment is Lys 75, which resides in helix IV (D. L. Newton and C. B. Klee, personal communication). Crystallographic studies of calmodulin complexes with drugs and receptor proteins will be of particular interest in elucidating the role of helix IV in these interactions.

One approach that can now be used to study structure/function relationships for calmodulin is to alter appropriate regions of the molecule to see how these modifications affect enzyme binding and activation. This is feasible as the chicken calmodulin gene has been cloned[6,15] and the cDNA has been introduced into bacterial expression vectors to yield large amounts of easily isolatable protein[36]. The chicken calmodulin gene is composed of eight exons and seven introns, five of the introns are in the amino-acid coding region[15]. One intron separates the DNA that encodes amino acids 82 and 83, thus interrupting helix IV and serving to separate the two homologous halves of the protein. Of the other helices, introns split only two: helix I between amino acids 10-11, a region not involved in Ca binding, and helix VII, between amino acids 139-140. This latter intron interrupts Ca-binding site 4. The remaining two introns interrupt Ca-binding loops 2 and 3, respectively. These data reveal that three of the four Ca-binding domains are interrupted by introns and therefore do not totally support the proposal that introns primarily divide the functional domains of proteins[42,43]. The current theory suggests that introns separate regions of proteins that are on the surface of the molecule[44]. The locations of all the introns in the calmodulin gene support this latter theory.

We thank Charles R. Mena and James G. Chafouleas for

assistance in the preparation of calmodulin samples. This research was supported by NIH grants GM-29427, CA-13148, DE-02670 and HD-07503. Low frequency variability and interstellar focusing

T. V. Cawthorne & B. J. Rickett*

Cavendish Laboratory, Madingley Road, Cambridge CB3 0HE, UK

The flux variations of extragalactic radio sources at low radio frequencies have proved very difficult to explain as changes in the luminosity of a simple synchrotron source. To circumvent this problem, several more complicated source models, such as those involving relativistic expansion of the source or coherent radiation mechanisms, have been devised. However, it has been suggested recently that the observed flux changes may be the result of a focusing effect of irregularities in the local interstellar medium. Here we present evidence which suggests that, in accordance with this explanation, low frequency variability is a more common feature of sources at low galactic latitudes. In the sample of radio sources monitored over a period of five years at Bologna, the mean galactic latitude of the variable sources is smaller than that of the non-variables to an extent that would occur with a chance of only 2% were the two groups drawn from the same parent distribution.

It is now firmly established that the low frequency ($\leq$1 GHz) flux density of some extragalactic radio sources varies on timescales of several months: the first conclusive evidence was provided by Hunstead[1] and there have since been several major monitoring programmes to search for variability—notably, those of Fanti *et al.*[2,3], using the Bologna telescope at 408 MHz, and Spangler and Cotton[4]. There are now more than 50 known low-frequency variable sources; most have flat radio spectra, normally associated with compact sources, and many are variable at higher frequencies.

If the flux variations are caused by changes in the source luminosity, the timescale on which they occur may be used to obtain an upper limit for the size of the source. Because the disturbance responsible for the change propagates with a speed less than that of light (c), the source diameter must be less than c (variation timescale)/$(1+z)$ where z is the redshift. However, variations in amplitude of several janskys on timescales of months in sources of moderate or high redshift require very large radiation brightness temperatures, well in excess of those that can be obtained from an incoherent synchrotron source[5]. Recently, however, Rickett *et al.*[6] have suggested that the variations are, at least in part, not intrinsic to the source, but the result of a refractive focusing effect of the general interstellar medium (A similar suggestion was made earlier by Shapirovskaya[7], in which the focusing irregularities were concentrated in galactic loop structures)

Small-scale irregularities in the density of interstellar electrons scatter waves into an angular spectrum of radius θ_{sc} and, for long wavelengths λ (typically $\geq$10 cm), interference among its components causes 100% modulations in the intensity of a point source, on scales of $\lambda/(2\pi\theta_{sc})$ in the plane normal to the direction of the source. It has been noted[8] that these modulations account for the scintillation of pulsars observed on timescales of order 10 min, at frequencies below 1 GHz. Assuming a power law spectrum of irregularities with power per unit wavenumber proportional to (wavenumber)$^{-(2+\alpha)}$, and a Kolmogorov spectrum ($\alpha = 5/3$), recent studies of pulsar scintillation[9] allow, that for a path length L through the galaxy, $\theta_{sc} = 6(\lambda\ \mathrm{m}^{-1})^{11/5}(L\ \mathrm{kpc}^{-1})^{3/5}$ marc s, which applies for a plane-wave source The distribution of scattering irregularities is often approximated by a layer of thickness $\pm$500 pc centred on the galactic plane, so that at galactic latitude b, $(L\ \mathrm{kpc}^{-1}) = 0.5\mathrm{cosec}(b)$ and $\theta_{sc} \simeq 4(\lambda\ \mathrm{m}^{-1})^{11/5}(\mathrm{cosec}\ b)^{3/5}$ marc s. These diffractive scintillations have never been observed for extragalactic radio sources[10,11], which is usually taken to mean that the angular diameters of such sources, θ_0, are sufficiently large that interference patterns from adjacent parts of the source are smeared over a distance $L\theta_0$, much larger than the scale of the patterns themselves, $\lambda/(2\pi\theta_{sc})$. The intensity modulations are thus completely levelled However, the large-scale irregularities present can also modulate the intensity by refractive focusing, which produces caustics in the wavefront from the source that are noticed as intensity fluctuations as the observer passes through them. The largest scale in the medium that

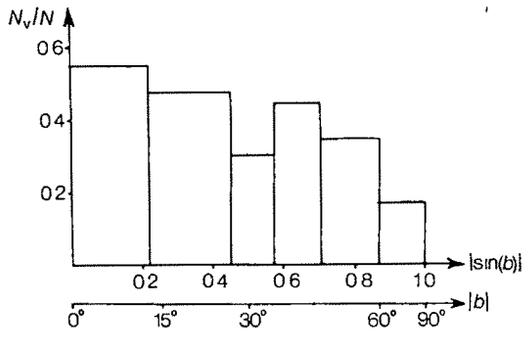

Fig. 1 The height of each bin represents the fraction (N_v/N) of sources from the Bologna sample that show fluctuations of amplitude >5% of the mean. In order of increasing $|b|$, the values for (N_v/N) are. 11/20, 9/19, 5/17, 9/20, 7/20 and 3/18.

can influence the radiation at any one point, is determined by the effective scattering disk of radius $L\theta_{sc}$ at distance L. For a power-law wavenumber spectrum, the increasing power in larger scales results in substantial modulation in the intensity of a point source on scales of $L\theta_{sc}$. The exact level of modulation depends on the power law exponent α and is particularly strong for exponents above four Nevertheless, measurements of laser scintillation in the atmosphere show that even Kolmogorov spectra give rise to 50–100% modulation[12]. Similar results are found for pulsars in the interstellar medium[6]. Compact extragalactic sources of diameter θ_0 should fluctuate as do pulsars if they are small enough ($L\theta_0 < L\theta_{sc}$). Even though this limit is much less stringent than that for diffractive scintillation, low frequency VLBI observations[13] suggest that, at metre wavelengths, most compact sources have $\theta_0 \geq \theta_{sc}$, so the refractive scintillations are at least partially quenched by smearing over a scale $L\theta_0$. The resulting modulation will be[6] $\Delta S_{rms}/S \approx \theta_{sc}/\theta_0$ on timescale $L\theta_0/2v$ where v is the relative velocity of the Earth and the scintillation pattern (10–100 km s^{-1}).

The foregoing theory makes predictions for the dependence of source variability on galactic latitude, which we have examined using the Bologna sample of Fanti *et al.*[3]. Figure 1 shows the most interesting result; the fraction of sources monitored that fluctuate with amplitude >5% of the mean is shown for each of six galactic latitude bins as a function of $|\sin(b)|$. The definite fall in this fraction with increasing latitude suggests that the variations are related to propagation in the interstellar medium. Because a χ^2 test takes no account of the order of the bins, it is not expected to attach great significance to this trend and, indeed, it does not. The Mann–Whitney test[14], which relies on the difference between the ranks of the variable and non-variable sources with galactic latitude, is far more appropriate. This test confirms that the variable sources have statistically lower galactic latitudes than those with steady fluxes; it yields a 2% chance that the two populations would be drawn in the manner observed from the same distribution in b. However, the possibility that this trend is caused by selection effects must be examined.

The Bologna sample is made up of several subsamples, consisting of sources chosen by known variability, flat spectra or interplanetary scintillations To produce the observed trend in a set of intrinsically variable sources by selection, at least one subsample would have to be strongly biased, either in favour of low latitudes, with an excess of variables, or in favour of high latitudes, with a deficiency of variables. Such an effect might arise if one subsample, biased towards low or high latitudes, was selected at very high or very low frequencies, respectively. One would then expect either an excess of flat spectrum sources (likely to be variable) at low galactic latitudes, or steep spectrum and probably extended sources (unlikely to vary) at high latitudes. However spectral information exists for most of the sources and spectral indices −dlog (flux)/dlog (frequency) can be found. Taking a flat spectrum source to have spectral index <0.5 in the region 0.5–5.0 GHz, there is no evidence to suggest that the flat and steep spectrum sources in the Bologna sample are differently distributed in b.

One may also restrict attention to sources in a narrow band of spectral index, across which there is little change in likelihood of variability. Almost all the sources with spectral index <0.2 are variable, but in the range of spectral indices 0.2–0.5, where there is no significant trend in spectral index with $|b|$, the variable sources again lie at systematically lower galactic latitudes than the non-variables, with a chance of <1% that the two populations would be drawn from the same distribution in b. Furthermore, the significance of the trend depends strongly on the dearth of variable sources above $|b| = 60°$, which is apparent (although not highly significant) in the larger subsamples, individually Therefore, it does not seem likely that the observed trend was produced by a dependence of spectral index on $|b|$, such as may arise through compiling the whole Bologna sample from its components. We cannot, of course, eliminate the possibility that unknown systematic effects are responsible for the presence of the trend within the subsamples.

Although the exact form that the focusing mechanism predicts for Fig. 1 depends on the source model assumed and the (unknown) distribution of angular sizes on milliarcsecond scales, the observed trend is clearly in the right sense. At a given latitude, the fraction of uniform sources that fluctuate with amplitude >5% of the mean is, from the above expression for $\Delta S_{rms}/S$, just that with angular size $\theta_0 < 20\,\theta_{sc}$, which will increase with θ_{sc} and hence with cosec(b). However, the sources will probably be inhomogeneous and, if at some $|b|$ θ_{sc} becomes sufficiently large that the scintillating components of most compact sources fluctuate with amplitude >5% of the total flux, then one would expect no further increase in the fraction of variable sources at lower galactic latitudes. This may account for the absence of a marked increase in the probability of variability at low b, where θ_{sc} increases most dramatically.

Using published data for the variable sources in the Bologna sample[15], we have looked for relations between galactic latitude and the amplitude and timescales of variation. None of the expected trends are apparent in these data, which may be because the published parameters describe individual outbursts rather than r.m s. variations. However, wide ranges in the fraction of flux coming from the compact component, in angular size θ_0 and in velocity of the Earth through the scintillation pattern, could also mask these effects. When metre wavelength VLBI data become available, the flux and diameter of a compact component may be used to explore further the relationships between amplitude, timescale, diameter and galactic latitude.

Although Fig. 1 suggests that the focusing mechanism is responsible for low frequency variations in many sources, there remains the possibility that some variations are intrinsic. In this context we note that, of six sources recently monitored[16], five varied almost simultaneously over a range of frequencies between 300 and 1,400 MHz, as the focusing mechanism predicts. One, however, exhibited brightening, with delays at lower frequencies, of the kind often associated with outbursts in a synchrotron source; this source may well be intrinsically variable.

Any source of observed diameter of the order of 10 marc s at a few hundred MHz that shows angular broadening, diminishing in diameter at higher frequencies, has $\theta_0 \leq \theta_{sc}$, and should undergo refractive scintillations with 50–100% modulation as do pulsars, on timescales comparable with other extragalactic sources. Such sources are important candidates for monitoring. It has been noted[17] that at very low galactic latitudes ($\lesssim 5°$), particularly towards the galactic centre, broadening is rather greater than is expected by extrapolating from that at high latitudes using the cosec(b) relation for L. Small-diameter sources seen along such paths should also fluctuate at centimetre wavelengths and it is plausible that several of the variable low-latitude sources, reported by Ryle *et al.*[18] and by Taylor

and Gregory[19], are extragalactic sources whose flux is modulated by refractive scintillation.

We thank Dr. L. Padrielli for discussion on the Bologna sample, Stephen Eales for advice on matters statistical, and Drs A. J. B. Downes and P. A. G. Scheuer for helpful comments.

Fermionic and bosonic interference during spin rotation through 2π radians

Herbert J. Bernstein

Massachusetts Institute of Technology, Cambridge, Massachusetts 02139
and *Hampshire College, Amherst, Massachusetts 01002, USA

Spinor wavefunctions change their sign under 2π rotation, an effect observable in interference experiments[1,2]. Several experiments have used magnetic precession of neutrons to implement rotations[3–7]. Other investigators have observed phenomena in molecular, nuclear or atomic systems with integral spin that have been identified as interference effects produced by 2π rotation[8–11]. I describe here a distinction between experiments on spin-1/2 neutrons and those on bosons, one that is crucial to interpreting these experimental results. Following recent work on interpreting magnetic precession as rotation[12,13], I show how to resolve Zeilinger's thought experiment[12], which actually measures the spin direction of two partial beams, with Byrne's point[13] that the recombined beam of neutrons has been rotated only π rad when the relative rotation between two partial beams is 2π. The essential distinguishing step lies in recognizing the lack of geometric significance, in general, of the mathematical parameter that equals 2π in the boson case.

When one transforms spin-1 states by true spatial rotation, the smallest covering angle (the first angle that restores original behaviour to a continuously rotated two-state subsystem) is π rad, not 2π rad. The observed sign change is nothing more than the (-1) of complete mirror reflection; such a reflection within a plane is exactly equivalent to a π rotation in three-dimensional space. This touches on the central problem of interpretation 'Is there any dynamic interaction that we may interpret as a pure rotation?'[14].

Although static magnetic fields generally cause additional effects, a uniform magnetic field that turns on after the particle enters does implement a pure spin rotation Here I suggest a new symmetrical neutron interference experiment, which, with static fields, clarifies why the spin of the recombined beam has rotated only π rad; with time-dependent fields, this configuration provides a feasible implementation of pure rotation. Indeed, the question posed above is addressed in the context of broader issues in the interpretation of quantum theory at the end of this letter. I begin by considering the relationship between rotations and dynamic interactions.

In quantum theory, certain unitary transformations represent spatial rotations, whereas others are used to represent the time evolution of a system. A rotation through angle θ in the x direction, for example, is $R_x(\theta) = \exp(-\imath\theta J_x/\hbar)$, where J_x is the operator for the x component of angular momentum, which may be calculated from the derivative, or generator, of the rotation

$$J_x/\hbar = i\, dR_x/d\theta|_{\theta=0} \tag{1}$$

Similarly, the hamiltonian, H, is a generator of the unitary time evolution operator, $U(t)$. If $|\Psi(t)\rangle = U(t)|\Psi(0)\rangle$, then the Schroedinger equation states

$$H/\hbar = i\, dU/dt|_{t=0} \tag{2}$$

assuming that H is time independent. The complications introduced to equation (2) by time-dependent interactions are exactly analogous to finding the angular momentum as a derivative at $\theta \neq 0$.

The analogy between equations (1) and (2) underlies all of the work on boson systems. In the simplest case, one finds a two-state subsystem where the hamiltonian induces transformations from one state to the other and vice versa, with equal transition probability, A, given by

$$H/\hbar = \begin{pmatrix} 0 & A \\ A & 0 \end{pmatrix} \tag{3}$$

which has the same form as the Pauli matrix for spin $\frac{1}{2}$,

$$\sigma_x/2 = J_x/\hbar = \begin{pmatrix} 0 & \frac{1}{2} \\ \frac{1}{2} & 0 \end{pmatrix} \tag{4}$$

Indeed, just as the general rotation

$$R_x^{1/2}(\theta) = \begin{pmatrix} \cos(\theta/2) & -i\sin(\theta/2) \\ -i\sin(\theta/2) & \cos(\theta/2) \end{pmatrix} \tag{5}$$

reduces to a phase factor (-1) when $\theta = 2\pi$, so a suitable evolution time for the hamiltonian in equation (3) also produces such a sign change. It is essentially this sign change that is measured by all boson experiments. The analogy between time evolution and rotation is the essence of the work on integral spin systems.

On the other hand, the idea of the neutron precession experiment relies on identifying the hamiltonian with the angular momentum. Indeed, to produce a true rotation, the hamiltonian must be proportional to the actual angular momentum of the system and not just to an analogue of a spin-$\frac{1}{2}$ operator[2,14]. This proportionality to angular momentum has double significance for interpreting the experiments: (1) the correspondence principle teaches that when energy is proportional to angular momentum, the interaction exerts a torque on the system, thereby causing it to rotate; (2) the parameter in equation (5) corresponds (as in the *gedanken* Stern–Gerlach experiments of ref. 12, or in its more feasible experiments using polarized neutron birefringence) to a measurable angle. By contrast, an actual 2π rotation of the analogous boson two-state subsystem produces no change of sign; the measurable rotation angle that results in sign change is π rad instead. This can be seen by considering the spin-1 example.

For a system of spin 1, with the usual basis set $\{|+1\rangle, |0\rangle, |-1\rangle\}$, labelled by $J_z/\hbar$, the generator of a z-axis rotation is diagonal. But transforming to a basis of $|x\rangle = 1/\sqrt{2}(|+1\rangle + |-1\rangle)$, $|y\rangle = 1/\sqrt{2}(|+1\rangle - |-1\rangle)$ and $|z\rangle = |0\rangle$, we find

$$J_z/\hbar = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \tag{6}$$

which clearly has a two-dimensional subspace (spanned by $\{|x\rangle, |y\rangle\}$) where it takes the off-diagonal form required by equation (3). Unlike the spin-$\frac{1}{2}$ generator (equation (4)),

* Address for correspondence

however, the non-zero elements are 1, not $\frac{1}{2}$. This difference makes the physical rotation, restricted to the $\{|x\rangle, |y\rangle\}$ subspace,

$$R_z^{1,\text{restricted}}(\theta) = \begin{pmatrix} \cos\theta & -i\sin\theta \\ -i\sin\theta & \cos\theta \end{pmatrix} \quad (7)$$

in clear distinction to the half-angle dependence in equation (5). Here it is obvious that the physical π rotation reduces to a sign change. Indeed, just as the states $|+1\rangle$ and $|-1\rangle$ correspond to spin fully up and down along the z axis, so the states $|x\rangle$ and $|y\rangle$ represent spin along the x and y axes, respectively. These act like well-behaved vectors in all respects, including complete return (no sign change) under 2π rotation and inversion when rotated by π rad about an axis perpendicular to their plane. Note that under $\pi/2$ rotation $|x\rangle$ becomes $-i|y\rangle$ and $|y\rangle$ becomes $-i|x\rangle$.

This last fact is probably the source of confusion in over-emphasizing the spinor analogy, for it is a π rotation that converts a spinor into its orthogonal complement. If the experiment (or, more exactly, its interpretation) identifies this conversion of $|x\rangle$ into $|y\rangle$ and vice versa with a spinorial π rotation, the analogy of doubling the physical angle is established. As a result, the first return to the initial states is analogous to a spinorial 2π rotation. Equation (7) shows this 'covering' return is actually a π rotation in physical space.

For non-scalar particles travelling at the speed of light, only two angular momentum states exist, which, in the case of photons, are the two distinct linear polarizations (and/or combinations thereof). If the direction of travel is the z axis, then the polarization of a single photon is a complex unit two vector in the x-y plane, essentially the direction and phase of the electric field vector of the corresponding electromagnetic wave. The physical rotation through angle ϕ about $\hat{z}$ (the caret denotes a real unit vector) is

$$R_z(\phi) = \begin{pmatrix} \cos\phi & -i\sin\phi \\ -i\sin\phi & \cos\phi \end{pmatrix}$$

in a basis where

$$\hat{x} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \; i\hat{y} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$$

Once again we see the full-angle dependence.

The space of all distinct polarization vectors, $\binom{a}{b}$, with $|a|^2 + |b|^2 = 1$, can be parametrized by points on a unit sphere in a fictitious three-dimensional space, where rotations are spinorial by definition. One can introduce angles ξ,η, exactly analogous to the usual θ,ϕ angles on a sphere, but the north and south poles of the ξ,η sphere are the spinor basis states, $\hat{x}$ and $i\hat{y}$. Orthogonal directions in space are thus represented by polar opposite points in spinor (ξ,η) space and the spinorial angle between states is twice the angle in physical space. Again, the 2π rotation in a fictitious spinor space is actually a π rotation in real space. This fictitious ('Faraday') space, with its rotation analogies, is of great use in understanding and picturing the relations among states of polarization, but its transformations are not physical space rotations[15].

The distinction between fermions and bosons can be extended to higher spins. For all fermions, true 2π rotations produce a sign change, whereas for bosons they do not. The smallest rotation angle that produces a sign change in a two-state subspace of spin J is π/J. For fermion spin greater than $\frac{1}{2}$ this is an odd submultiple of 2π, which means that a 2π rotation may be composed of these smaller rotations, by multiplying them together. Then the (-1) factor appears raised to an odd-integer power; the full 2π rotation, therefore, also changes sign. For bosons π/J is an integral submultiple of π and a 2π rotation therefore produces the factor $(-1)^{2J}$, that is, no sign change.

In general, taking m (the angular momentum component along the rotation axis) as a label, we have $R(\theta)|m\rangle = \exp(-im\theta)|m\rangle$. The value of m ranges from $-J$ to $+J$ in steps of one unit, where J is the total spin (half-integral for fermions, integral for bosons). Because this includes the values $m = \pm 1$ for non-scalar bosons and $m = \pm\frac{1}{2}$ for fermions, the smallest angle producing a sign change of the entire space of states is always π for bosons and 2π for fermions.

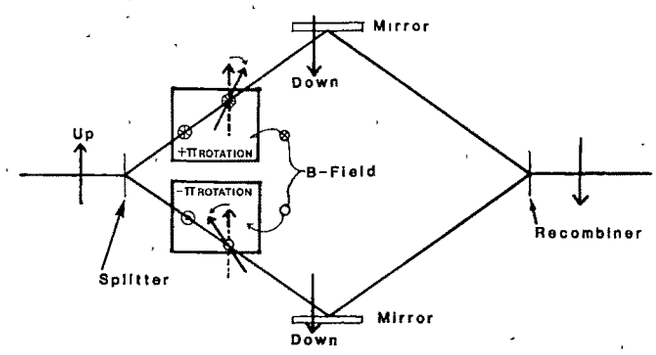

Fig. 1 A symmetric magnetic precession experiment (schematic).

In the highest and lowest m $(= \pm J)$, choosing the basis $|+\rangle = 1/\sqrt{2}(|J\rangle + |-J\rangle)$ and $|-\rangle = 1/\sqrt{2}(|J\rangle - |-J\rangle)$ makes the rotation matrix

$$R_z^{J,\text{restricted}}(\theta) = \begin{pmatrix} \cos(J\theta) & -i\sin(J\theta) \\ -i\sin(J\theta) & \cos(J\theta) \end{pmatrix} \quad (8)$$

from which it follows that sign change first occurs for $\theta = \pi/J$, as stated above. This is particularly important for the case of a particle travelling at the speed of light, because its two polarization states are precisely $|+J\rangle$ and $|-J\rangle$, hence $|+\rangle$ and $|-\rangle$ are a natural basis for the rotations. The cases of $J = \frac{1}{2}$ and 1, corresponding to neutrino and photon respectively, fit formulas given above. The one other massless entity in modern physics, that is the 'graviton', has spin 2. Pictures (p. 230 of ref. 16) of acceleration for linearly polarized gravitational waves clearly show the rotation effect described above: the value of J for bosons denotes a J-fold symmetry of the transverse oscillations in the case of light-like radiation.

What of the interpretation of the neutron spin precession as rotation? Zeilinger's clever thought experiment[12] actually measures the spin direction of two partial beams, providing a physical demonstration of the rotation, whereas Byrne[13] points out that the recombined beam has been rotated by only π rad when the relative rotation between partial beams is 2π.

That both authors are correct is directly demonstrated by a 2π-rotation experiment performed symmetrically, with a positive π rotation along one path and a negative (or opposite-sense) π rotation along the other path. In some cases, this symmetrical rotation scheme could help eliminate possibilities for determining along which path the neutron travelled, for example, by using a common source for the two fields and arranging that any magnetic energy exchange be the same for both possible paths. As is well known in quantum theory, if one can tell which path was taken, the phase coherence between the paths is destroyed and the interference is not observable. If the 2π rotation experiment were done asymmetrically, the passage of a neutron dipole moment through the magnetic field along one path might conceivably produce detectable back reaction, signalling which path it took. Almost certainly there would be some additional phase shift, beyond the expected sign change resulting from 2π rotation, because of the asymmetry.

If we examine the symmetrical experiment (see Fig. 1), we immediately notice that the π rotations produce the same orientation of neutron spin, whichever path is taken. Thus, if the initial spin is 'up' (as in Fig. 1), then the spin of each partial beam will be 'down' when they are about to recombine. The recombined beam is also spin 'down'. Note that this experiment would not require a polarized initial beam because the same π rotation effect occurs with a spin 'down' particle Of course, to follow the spin by, say, Zeilinger's Stern-Gerlach apparatus would require a polarized beam.

These remarks about orientation apply equally to bosons. For example, consider a spin-1 case and let 'up' denote the state $|x\rangle$

defined above. Equation (7), with $\theta = \pi$, shows that positive π rotation transforms $|x\rangle$ to $-|x\rangle$. But so does $\theta = -\pi$; the recombined beam points in the 'down' direction, opposite 'up'. This accords with Fig. 1, but produces no relative phase between the two beams, so there is no difference in the interference pattern from the case of zero rotation An observable sign change occurs at smaller rotation, namely, $\theta = \pm\pi/2$.

The fact that the combined spin direction after a 2π relative rotation is only π rad away from the initial direction is a special case of superposition of two equal-intensity coherent spinors. In general, the spin of the superposition lies in the plane bisecting the angle between the two spin vectors. This can be seen quickly in spinor algebra. For simplicity, take the x–z plane to contain both the combining spinors and let the x axis be their angle bisector (see Fig. 2). This is just a choice of coordinate axes If we use the convention that

$$|\theta, \phi\rangle = \begin{pmatrix} \cos(\theta/2) & e^{-i\phi/2} \\ \sin(\theta/2) & e^{+i\phi/2} \end{pmatrix} \tag{9}$$

where θ,ϕ are the colatitude and azimuthal angles, respectively, we have

$$|\psi^{\text{recombined}}\rangle \propto \left(\left| \frac{\pi}{2} - \eta, 0 \right\rangle + \left| \frac{\pi}{2} + \eta, 0 \right\rangle \right)$$

$$|\psi^{\text{recombined}}\rangle \propto \cos\frac{\eta}{2} \begin{pmatrix} \frac{1}{\sqrt{2}} \\ -\frac{1}{\sqrt{2}} \end{pmatrix} = \cos\frac{\eta}{2} \left| \frac{\pi}{2}, 0 \right\rangle \tag{10}$$

If we take η as the individual rotation angle, π, in the symmetric 2π rotation experiment, then equation (10) implies a vanishing amplitude for the recombined state that reflects the perfect destructive interference attributable to the (-1) phase factor induced by one full rotation. (In the notation of Byrne's paper[13], $\beta = 2\pi$; and $A = B$, that is the parameters characterizing the intensity of the recombining beams are equal, imply the vanishing of the recombined beam itself, for no particles (ideally) would be transmitted. Byrne's equation (3) reflects this—the transmission coefficient drops to zero for these values. His point about the spin polarization is nevertheless correct; it does suffer a rotation of π rad Experimental confirmation would require taking the limits as $\beta \to 2\pi$ and seeing the polarization approximate rotation by π as closely as one likes.)

It is interesting briefly to consider the effects of a relative phase shift, α, on the recombined beams. In this case, spinor addition gives

$$|\phi^{\text{recombined}}\rangle \propto \left(e^{-i\alpha/2} \left| \frac{\pi}{2} - \eta, 0 \right\rangle + e^{+i\alpha/2} \left| \frac{\pi}{2} + \eta, 0 \right\rangle \right)$$

$$= \sqrt{\cos^2(\alpha/2)\sin^2(\eta/2) + \sin^2(\alpha/2)\cos^2(\eta/2)}$$

$$\times \left| \frac{\pi}{2}, 2\tan^{-1}(\tan(\eta/2)\tan(\alpha/2)) \right\rangle \tag{11}$$

Previous work[2,14] has discussed the fact that a static magnetic field introduces precisely such a relative phase shift, as well as the desired rotation, in an asymmetrical relative rotation experiment. This small extra phase shift arises because the static configuration conserves energy. Neutrons with spin parallel to the field increase their kinetic energy, spending less time in the field than those aligned oppositely. The resulting phase shifts are not precisely equal and opposite. That in such an experiment the rotation is not pure, would be revealed in these spin-tracking experiments by arriving at a recombined polarization that lies in the x–y plane, but not precisely along the x axis.

Note that various interactions can produce the hamiltonian of equation (3), which results in a time evolution operator

$$U(t) = \begin{pmatrix} \cos(At) & -i\sin(At) \\ -i\sin(At) & \cos(At) \end{pmatrix} \tag{12}$$

For the slightly more complicated case where A is a function of time, the product At is replaced by the integral $I(t) = \int_0^t A(\tau)\, d\tau$. Then

$$U(t) = \begin{pmatrix} \cos I(t) & -i\sin I(t) \\ -i\sin I(t) & \cos I(t) \end{pmatrix}$$

But the relationship between the product At, or $I(t)$, and a physical rotation angle (if any) depends on the angular momentum, J, of the system. H must be proportional to J to identify $U(t)$ as a rotation. The advantage of magnetic precession as a means of performing rotation lies in the well-established proportionality of the hamiltonian to the magnetic moment and hence to angular momentum. Even so, as stated above (and developed previously[12,14,17]) certain magnetic field distributions produce additional phase shifts. Thus, one must be careful of the theoretical analysis that undertakes identification of any dynamical process with a rotation. For it is well known that interactions produce phase shifts that can mimic those produced by physical rotations of either the reference system (passive rotations) or of the state-preparation devices (active rotations).

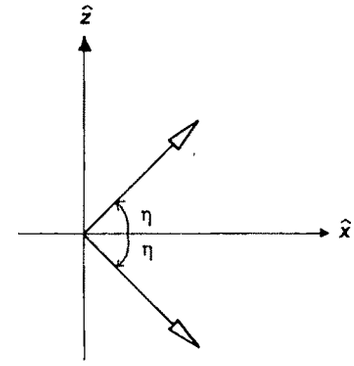

Fig. 2 Addition of spinors.

More directly, to identify a transformation as a rotation requires a physical rotation angle and preferably one that is, in principle, directly measurable. Zeilinger's analysis shows how to make such measurements during magnetic precession. The issue of such a geometric (or macroscopic) correlative of the spin, for polarized neutrons, undergoing precession has been raised in the earlier literature on the interpretation of these experiments[13,17–21]. The suggestion of using a strong static helical field (whose change of direction in space could be easily measured) was an early step in this direction[21]. Such a field entrains the moment of the polarized neutron and guides it around in space. The theory shows that in the asymmetric case such a helical static configuration also produces only approximate rotations[14,20–22]. The approximation involved is so good (often better than 1 part per 10^{12}) that it enters the discussion only at the level of interpretation Nevertheless, every time-independent magnetic field thus far examined requires these approximations in order to be interpreted as a true rotation.

By contrast, the investigation of precession in time-dependent (as opposed to space-dependent) magnetic fields[14] shows exact reproduction of the effect of rotation; that work left only one question—whether such fields could be found that also satisfy Maxwell's equations—now answered affirmatively. An infinite sheet of uniform current density, starting up from zero to a finite value and returning to zero again, produces a plane-wave electromagnetic 'pulse' whose magnetic field fulfills the requirements. The details of this configuration, with discussions of its possible implementation will be published elsewhere (H.J B., in preparation).

The deepest issue of interpretation lies in determining when, if ever, an interaction may be considered to produce a symmetry transformation. The issue is joined in noting that torques must be applied to any spinning object to rotate it. These torques imply (certainly for a quantum mechanical system) entanglement with a macroscopic system, such as the magnetic field in the neutron experiments.

Wheeler[23] terms the sign change of a spinor under 2π rotation its 'entanglement relation', referring to the model of a macroscopic object tied (by elastic strings, ribbons or a strip of material) to its surroundings. Under 2π-rotations the strings become irremediably entangled, but after 4π-rotation they may be topologically restored to the untangled state without rotating the object. This 'entanglement relation' underlies a variety of popularized demonstrations of spinor properties. Dirac was fond of twisting his belt to show it. A triangular lecture-hall model has been described[21], but perhaps the most beautiful demonstration is that of the Phillipine Binasuan dance[24]. The causal connections of interaction may be less surprising than those of correlation (as in recent implementations of the Einstein-Rosen-Podolsky 'paradox'[25]), but even if they turn out to be pictured or controlled more easily, they are no less real.

I thank Professors J. Byrne and A. Zeilinger for conversations that prompted this paper and A. Zeilinger, M. Horne, C. Shull and D. Gilden for discussion of its first draft. I also thank Professor Shull for providing the hospitality and support of the Massachusetts Institute of Technology Neutron Diffraction Laboratory during the completion of this work, which was partially supported by NSF grant No. 8316209-DMR.

Evidence from polar ice cores for the increase in atmospheric CO_2 in the past two centuries

A. Neftel, E. Moor, H. Oeschger & B. Stauffer

Physics Institute, University of Bern, Sidlerstrasse 5, CH-3012 Bern, Switzerland

Precise and continuous measurements of atmospheric CO_2 concentration were first begun in 1958 and show a clear increase from 315 parts per million by volume (p.p.m.v.)[1] then to 345 p.p.m.v. now. A detailed knowledge of the CO_2 increase since preindustrial time is a prerequisite for understanding several aspects of the role of CO_2, such as the contribution of biomass burning to the CO_2 increase and the sensitivity of climate to the CO_2 concentration in the atmosphere. Estimates of the preindustrial CO_2 concentration are in the range 250–290 p.p.m.v. (ref. 2), but the precise level then and the time dependence of the increase to the present levels remain obscure. The most reliable assessment of the ancient atmospheric CO_2 concentration is derived from measurements of air occluded in ice cores. An ice core from Siple Station (West Antartica) that allows determination of the enclosed gas concentration with very good time resolution has recently become available. We report here measurements of this core which now allow us to trace the development of the atmospheric CO_2 from a period overlapping the Mauna Loa record back over the past two centuries.

Air bubbles are a characteristic feature of natural ice. At locations with mean air temperatures well below the freezing point, ice is formed by sintering of dry firn. At the firn–ice transition, the pore volume becomes separated as isolated bubbles having no further interaction with the atmosphere. The transition process is slow, so that the sampling of air into isolated bubbles spans at least several years, the duration depending mainly on the accumulation rate and the mean annual temperature.

Measurements were made on a 200-m ice core drilled in the Antarctic summer 1983/84 at Siple Station (75°55′ S, 83°55′ W) by the Polar Ice Coring Office in Nebraska and our institute. The mean annual air temperature is −24 °C and the annual accumulation rate is 500 kg m^{-2}. Only one clearly identifiable melt layer of irregular thickness (2–10 mm) was observed in the entire core at 7 m below surface (m.b.s.). Counting the seasonal variations of the electrical conductivity of the ice core allowed us to date the core over the past 200 yr with an accuracy of

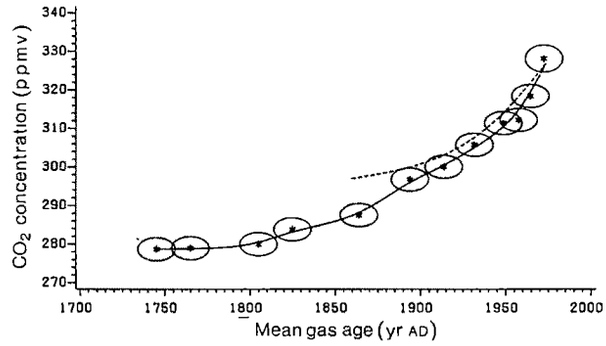

Fig. 1 Measured mean CO_2 concentration plotted against the estimated mean gas age. The horizontal axis of the ellipses indicates the close-off time interval of 22 yr. The uncertainties of the concentration measurements are twice the standard deviation of the mean value, but not lower than the precision of 1% of the measurement. The dotted line represents the model-calculated back extrapolation of the atmospheric CO_2 concentration, assuming only CO_2 input from fossil fuel[2].

Methods. After crushing the ice samples, the gas expands over a cold trap, condensing the water vapour at −80 °C into the absorption cell. Care was taken to minimize the effect of selective transport of CO_2 by water vapour. This effect was discovered while testing the system, when a difference in the measured CO_2 concentration was observed depending on whether the valve between the crusher and the cold trap was open or closed during the crushing process. With the valve closed, the concentrations were systematically higher by ~15 p.p.m.v. Crushing the ice with the valve open causes small ice particles to be transported to warm surfaces, where they immediately evaporate, leading to a considerable amount of water vapour in the system. The part of this water vapour not immediately condensed in the cold trap expands into the absorption cell and then flows slowly back into the cold trap, as indicated by the pressure monitoring in the absorption cell, which leads to a decreased CO_2 concentration in the absorption cell. When the valve is closed, the ice particles created during the crushing process are kept back in the cold crusher and less water vapour reaches the absorption cell after the valve is opened, leading to smaller deviations of the CO_2 concentration. Also, for this slightly modified measuring procedure, the measurements could be controlled by crushing pure gas-free single-crystal ice surrounded by the same amount of standard gas as contained in an average ice sample. With this procedure, small positive deviations in the CO_2 concentration, attributable to water vapour flow from the crusher into the cold trap, can be determined and the measurements corrected accordingly. This correction is below 1% for 10-cm^3 samples and below 4% for 1-cm^3 samples. All Siple samples were measured using the modified procedure and each fourth measurement was a calibration run.

Table 1 Mean CO_2 concentration in air extracted from ice samples

Depth below surface (m)	Samples measured	Ice from (yr AD)	Air enclosed (yr AD)	CO_2 concentration: Extracted air (p.p.m.v.)	CO_2 concentration: Atmosphere (p.p.m.v.)

LES, Large extraction system.

±2 yr (ref. 3). Based on porosity measurements, the time lag between the mean age of the gas and the age of the ice was determined to be 95 yr and the duration of the close-off process to be 22 yr (ref. 4). These values are, of course, evaluated for one particular core representing the present situation (1983), assuming a homogeneous enclosure process and not taking into account the sealing effect of observed impermeable layers.

The gases from ice samples were extracted by a dry-extraction system, in which bubbles are crushed mechanically to release the trapped gases, and then analysed for CO_2 by infrared laser absorption spectroscopy (IRLS) or by gas chromatography (GC). The combination of a needle crusher and IRLS allows us to analyse samples of ice as small as 1 g (ref. 5) (see Fig. 1 legend). During the past 2 yr, a new large dry-extraction device for ice samples up to 1 kg has been built and extensively tested[6]. The ice samples are ground *in vacuo* and the gases collected on a cold finger (20 K) and later analysed by both GC and IRLS. Applying both procedures to neighbouring ice samples gave the same concentration to within 1%. The measurements using the needle crusher, published previously[5,7,8], were performed using a slightly modified procedure and exhibited generally lower CO_2 concentrations by 15 p.p.m.v. (see Fig. 1 legend). In 1982 an intercalibration study with the Grenoble laboratory[7] was performed using the small crusher with the older measuring procedure. Based on our new results, the agreement of the intercalibration must be viewed as a discrepancy, which we will try to resolve in the near future with a new intercalibration series.

Figure 1 shows the mean CO_2 concentration of the 12 depth intervals, measured on the Siple core, plotted against the mean gas age To extend our data series further back in time, a few samples from the South Pole were also measured (and cross-checked with the large extraction system). These values are listed in Table 1.

Five depth intervals between 82 and 130 m.b.s. of the Siple core were measured with a high spatial resolution. Figure 2*a–e* shows the individual data series together with the $\delta^{18}O$ results. A seasonal structure could not be identified, indicating that the CO_2 concentration in the bubbles of the Siple core is homogeneously distributed and is independent of the seasonality of the surrounding ice.

Based on earlier studies of ice samples from locations in Greenland, we expected to measure enhanced CO_2 concentration in the extracted gas, especially in summer layers[8,9] from locations with a mean annual air temperature above −25 °C. For comparable mean gas ages, the CO_2 concentration measured on samples from the South Pole (−50 °C) and Siple Station (−24 °C) do not differ within the error limit. Therefore, we conclude that the CO_2 level in the bubbles of the Siple core is not influenced by a temperature effect. This is further supported by the lack of seasonal variations in the five data series measured with high spatial resolution.

Between 68 and 69 m.b.s., the porosity measurements showed two layers with bubble volumes above 80 $cm^3\ kg_{ice}^{-1}$, which correspond to complete enclosure. This is clearly above the 40 $cm^3\ kg_{ice}^{-1}$ expected from a smooth homogeneous enclosure process. These impermeable layers have a sealing effect if they are imbedded in firn with reduced permeability[10]. Because of the layers between 68 and 69 m.b.s., the air below is already completely isolated, about 7 m above the depth obtained, assuming a homogeneous enclosure. Consequently, for this core, the difference between ice and mean gas age is only 80–85 yr instead of 95 yr as estimated previously[4].

The enclosure of air occurs in winter layers at shallower depth than in summer layers, which could lead to a seasonal modulation of the CO_2 concentration in the bubbles during a period of changing atmospheric CO_2 concentration in case of a smooth and homogeneous enclosure process. The abovementioned lack of a seasonal variation in the series from 82 m.b.s. therefore further supports the sealing effect of such layers.

If the 328 p.p.m. measured at a depth of 68.5 m.b.s. is matched with the atmospheric South Pole record[11], the mean gas age is 10 yr, corresponding to a difference between mean gas age and ice age of 82 yr, which lies in the above estimated range. This difference is used in calculating the mean gas age for all depths. That the CO_2 concentration measured on the subsequent samples from 72.5 and 76.5 m.b.s. corresponds with the atmospheric South Pole record justifies this age determination and indicates, also, that impermeable layers at a depth of ~68 m.b.s. occur frequently.

There remains the question of the duration of the gas-enclosure time in such an impermeable layer. Assuming, as a first approximation, a constant and continuous enclosure rate ending at the time of core drilling (t_2 = AD1983), the beginning (t_1) can be calculated from the expression $(t_2 - t_1)C_{bubbles} = \int_{t_1}^{t_2} C_{atm}(t)\,dt$, where $C_{atm}(t) = a + b(t-1958) + c(t-1958)^2$ (with t in yr AD). The atmospheric concentration, C_{atm}, is taken from a quadratic fit of the measured CO_2 data in the atmosphere. The time t_1 so determined is 1963, so that the duration of the close-off is 20 yr, in good agreement with the estimate of Schwander and Stauffer[4].

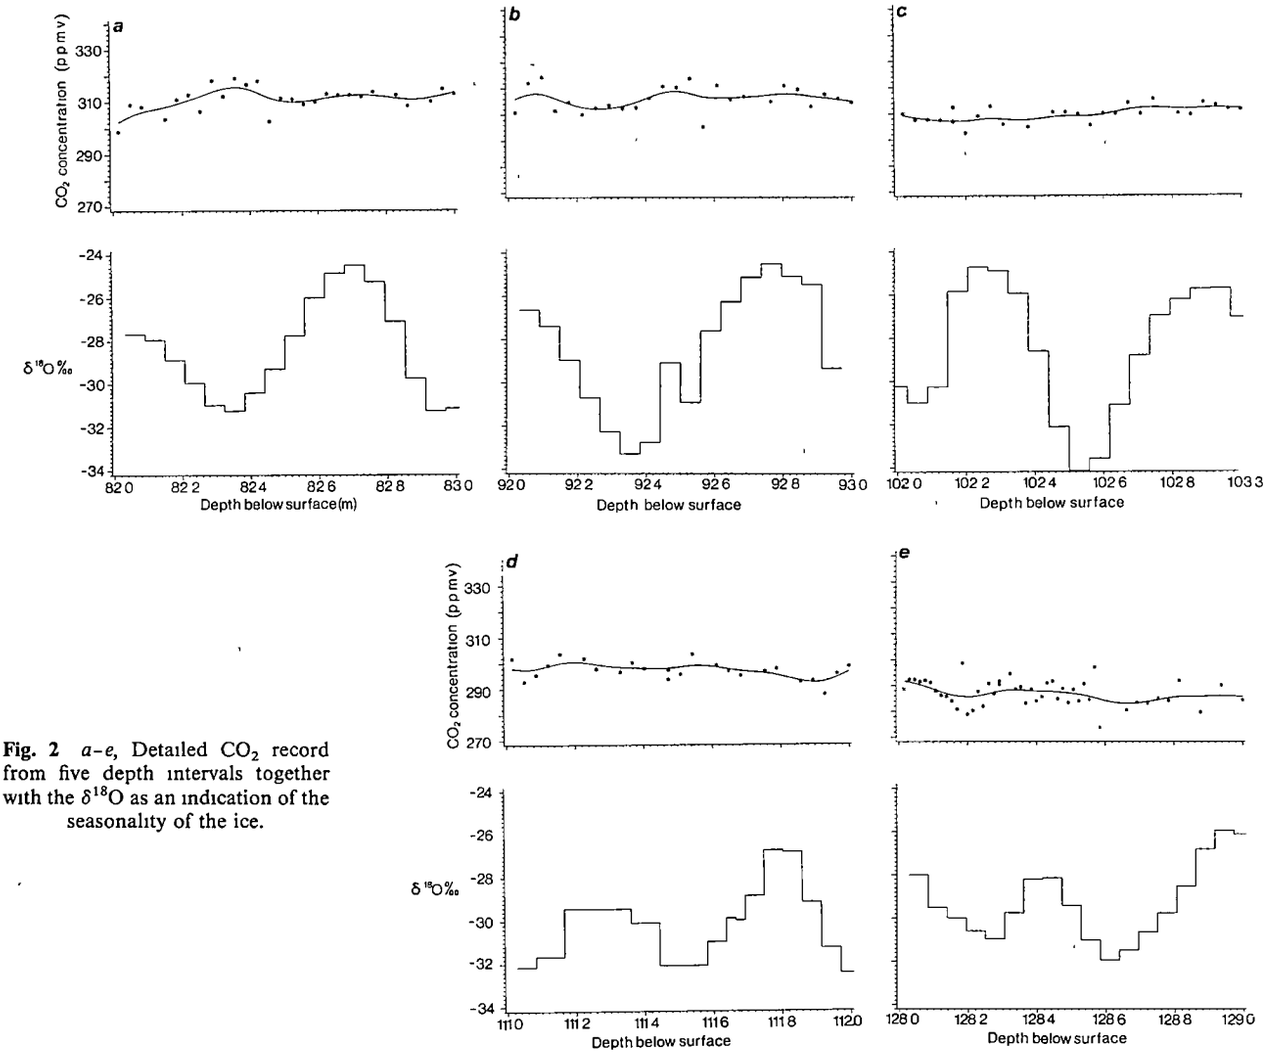

Fig. 2 *a–e*, Detailed CO_2 record from five depth intervals together with the $\delta^{18}O$ as an indication of the seasonality of the ice.

We would have more difficulties explaining values lower by 15 p.p.m.v., as obtained, for example by the open-valve method. This would require a 20–40-yr-older mean gas age in the bubbles, depending on the development of the atmospheric CO_2 concentration. A very much prolonged close-off interval, a possibility which we exclude[4], or an incomplete mixing of air in the firn would be required. Also, the atmospheric CO_2 concentration would have to be increased between 1930 and 1960 by $\sim$1 p.p.m.v. yr^{-1}, a similar rate to that of the past 20 yr.

Based on these results, we conclude that the atmospheric CO_2 concentration around 1750 was 280 ± 5 p.p.m.v. and has increased since, essentially because of human factors, by 22.5% to 345 p.p.m.v. in 1984. Back extrapolation of the Mauna Loa curve, on the basis of the fossil fuel input data obtained by Rotty[12] and assuming zero CO_2 input from biomass burning, suggests a preindustrial level of 297 p.p.m.v. (ref. 2). The difference of 17 p.p.m.v. between this calculated value and that measured indicates a significant contribution from biomass burning, even during the past century when the contribution from fossil fuel consumption was still small. The CO_2 increase in the Siple core will be studied in more detail using $\delta^{13}C$ measurements. Preliminary $\delta^{13}C$ results on an ice core from the South Pole are indeed very promising[13]. The CO_2/air $^{13}C/^{12}C$ record on the Siple ice core and the $^{14}C/^{12}C$ Suess effect from tree rings, together with the fossil fuel input-time history, will then enable us to separate the CO_2 inputs from those attributable to fossil fuels and biomass. It will also allow us to determine the effective airborne fraction for the combined input and to check the validity of the present carbon-cycle models

We thank Drs J. Schwander, W. Bernhard, K. Hänni and R. Walther for assistance with the field work and with the analysis in the laboratory. We also thank D. Raynaud for reviewing the manuscript. This work was supported by the Swiss National Foundation, the Department of Polar Programs of the NSF, the US Department of Energy and the University of Bern.

Vertical structure of the Brazil Current

David L. Evans

Graduate School of Oceanography, University of Rhode Island, Kingston, Rhode Island 02881, USA

Sergio S. Signorini*

Universidade de Sao Paulo, Instituto Oceanografico, Sao Paulo, CEP-05508, Brazil

Recent interest in world climate and interaction of the ocean and atmosphere have led to studies of the meridional fluxes of fresh water and heat in the ocean[1,2]. Several such studies[3,4] have noted the asymmetry of heat fluxes between the North and South Atlantic oceans. In particular, the fluxes across both 24° N and 24° S appear to be northward. Crucial to all of the direct calculation techniques is an accurate estimate of the transport of the western boundary currents. In the North Atlantic, useful measurements in the Florida Current[5] over a long period of time are available. For the much less studied South Atlantic no comparable time series has been made. The direct measurements of Brazil Current velocities near 23° S reported here show southward flow of warm water above 400 m depth and northward flow of Antarctic Intermediate Water below that. The upper layer transport was $\sim 6 \times 10^6$ m^3 s^{-1} towards the south offshore of the 200-m isobath, with an indication of comparable flow on the shelf.

The Brazil Current is the South Atlantic analogue of the Gulf Stream. For the present purposes, it is defined as the southward-directed western boundary current, extending downward from the surface, closing the circulation of the subtropical, wind-driven circulation in the South Atlantic. From a consideration of the wind-driven anticyclonic gyres, the two should be quite similar. As Stommel[6] points out, "therefore ... the wind-driven component of the circulation is much the same in the two hemispheres, but ... in the western boundary currents the thermohaline circulation plays quite different roles in the Gulf Stream and Brazil Current, making the former appear much more strongly on the charts of the topography of surfaces, equal pressure, or density". Indeed, the limited historical hydrographical observations indicate that the total transport of the Brazil Current may be no larger than 9.4×10^6 m^3 s^{-1} in the upper 600 m (refs 7, 8). However, as Stommel remarks, the wind-driven component should be as large as $30\text{–}40 \times 10^6$ m^3 s^{-1} to balance the equatorward transport in the gyre. Recent calculations based on balancing the meridional transport due to the wind stress curl[9,10] indicate that up to 30×10^6 m^3 s^{-1} should flow in the Brazil Current near 30° S and $\sim 20 \times 10^6$ m^3 s^{-1} should flow at 25° S.

There are longstanding beliefs that western boundary currents provide an essential means for meridional transport and that the Brazil Current region may be the major conduit for the exchange of at least four major water masses between the hemispheres[11]. In contrast, inverse calculations indicate that the Brazil Current may be important only south of 25° S. In fact, these calculations indicate little southern transport along the boundary north of 30° S (ref. 4). Previous work has relied on water mass boundaries or more arbitrary fixed depths to determine levels of no motion for calculation of geostrophic transport. There have been no systematic investigations of the Brazil Current including direct velocity or transport measurements.

The choice of reference level for geostrophic calculations leads to an ambiguity in even the direction of flow of some of the water masses along the boundary. Traditionally, water mass analysis suggested a layered current system with warm tropical water flowing southward over northward Antarctic Intermediate Water which is in turn above the southward-flowing North Atlantic Deep Water[12]. More recent interpretation of the data has led some investigators to argue that the wind-driven gyre penetrates deep enough to carry Intermediate Water to the south after circulating around the basin[4,13]. Resolution of the issues of transport of the Brazil Current and its vertical structure, that is, direction of flow of the various water masses, motivated the present study. The results presented below indicate that the 'Brazil Current' should be reserved for the flow shallower than ~400 m at this latitude.

A cruise aboard the *Prof. Besnard* of the Institute of Oceanography at the University of Sao Paulo during April 1982 allowed a detailed expendable bathythermograph (XBT) survey and hydrographic study between 19° S and 24° S to be performed. Essentially, the Brazil Current was found to be closely confined to the region near the continental slope. It flowed continuously past the seamount chain at 20°30′ S through the most inshore passage and onto the continental shelf. Geostrophic transports were $< 10 \times 10^6$ m^3 s^{-1}, using either 500 m or 1,000 m as a reference level[14]; they were 3.8×10^6 m^3 s^{-1} and 6.8×10^6 m^3 s^{-1} respectively.

The first direct velocity measurements of the Brazil Current were made in April 1983 aboard RV *Oceanus*. The XBT survey from 19° S to 24° S was repeated in greater detail and extended further offshore than in April 1982. The Pegasus velocity profiler[15] was deployed at two passages in the seamount chain at 20°30′ S and along five sites across the Brazil Current near Cabo Frio between 23° S and 24° S to obtain vertical profiles of horizontal velocity with an estimated accuracy of ± 2 cm s^{-1}. Figure 1 shows the survey area and location of XBT lines and Pegasus sites. Also shown is the depth of the 15 °C isotherm, the gradient of which is indicative of the strength of the baroclinic component of the flow.

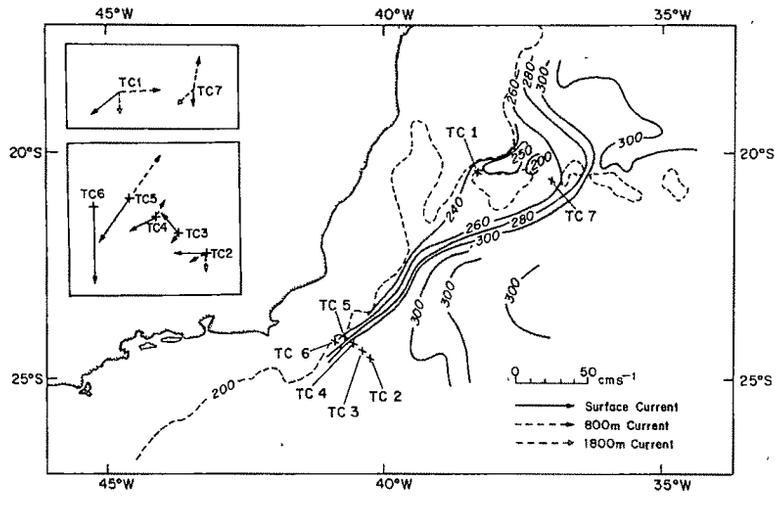

Fig. 1 Survey area for April 1983 cruise showing depth of the 15 °C isotherm and locations of Pegasus stations. Also shown are mean velocity vectors at depths characteristic of surface, intermediate and deep waters

* Present address: E.G&G. Corporation, Waltham, Massachusetts, USA

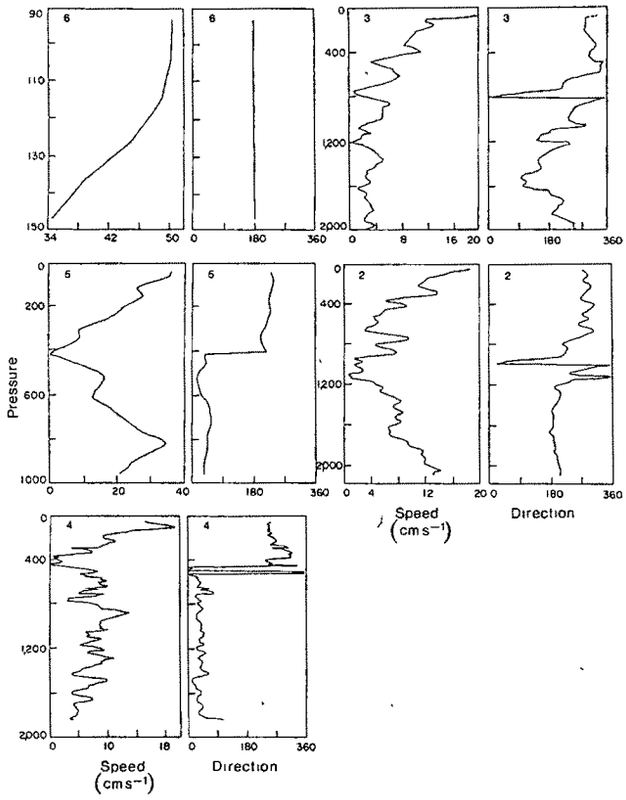

Fig. 2 Vector-averaged profiles of speed and direction at each Pegasus site. Directions are measured as degrees true towards which the current flows (Note the difference in pressure and speed scales among the frames Depths are in decibars.)

Offshore from the 2,000-m isobath and near the Abrolhos Banks, the temperature gradient field is poorly organized and there is no clear indication of baroclinic flow. Based on the temperature gradients alone, the Brazil Current seems to be flowing through the banks with weaker intensity than along the 200-m isobath near Cabo Frio, where it is confined to flow in a narrow stream along the shelf-break. This pattern is essentially the same as found in April 1982 except that there is a suggestion of flow to the east of the banks at 20°30′ S. Earlier work[7,8,14] has shown that a close relationship between temperature (T) and salinity (S) in this region permits inference of geostrophic flow from the temperature field to within an accuracy of ±10%.

Each of the Pegasus sites TC2–TC6 was visited three times during a period of 10 days. Only two measurements were made at TC1 and one at TC7. Although the profiles over the course of the cruise showed small variability, they represent only one snapshot of a field which is likely to have large variability at longer timescales. We may hope that, like the Gulf Stream, the vertical structure is relatively stable. Figure 2 displays the vector-averaged profiles of speed and direction for the section near Cabo Frio[15]. The east and north components of velocity were interpolated to common depths at approximately the original resolution using cubic splines. Vector averages of the three drops at each site were then computed. Figure 3 exhibits all three profiles from site TC5 to illustrate the relatively small variability among the drops.

Site TC2 was selected, based on the isotherm pattern from the XBT survey, to be offshore of the Brazil Current. The surface flow is <20 cm s^{-1} and is directed to the west (or north-west) down to 1,000 m. Between 1,000 and 1,200 m the velocity vector is small (<3 cm s^{-1}) and rotates through 360° with depth. Such flow may be characteristic of the subtropical gyre circulation to the east of the boundary current. However, an XBT line along 36° W failed to indicate significant zonal flow and the surface flow does not indicate an eastern source (Fig. 1). From 1,400 m to the bottom, the flow is directed almost due south. Deep southward flow in the absence of a similar surface current is

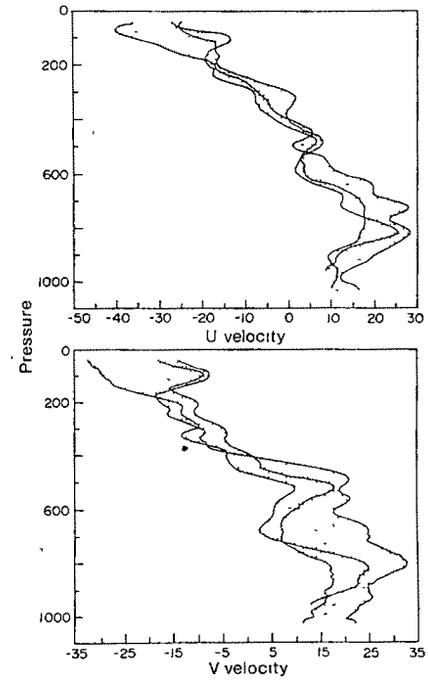

Fig. 3 East and north components of three drops at site TC5. Data were collected over 1 week

not taken to be indicative of the Brazil Current, but is likely to be part of the deep thermohaline mode. At TC3, the next station inshore, all speeds are <20 cm s^{-1}. Surface layer flow is directed to the north-west down to a depth of 500 m. Below 600 m, speeds are quite weak and directions are consequently not well determined. TC4 is the first station definitely in the Brazil Current. In the layer from the surface to 400 m, the current is directed towards the south-west at speeds up to 20 cm s^{-1}. Below 500 m, the water moves northeastward at speeds near 10 cm s^{-1}. TC5 again shows the dramatic change in direction near 400 m depth. The upper layer (traditional Brazil Current water) moves to the south-west at speeds up to 35 cm s^{-1}. Below 400 m, the flow is directed towards the north-east, also at speeds of up to 35 cm s^{-1}. (The salinity minimum, indicative of Intermediate Water, is found near 800 m at this location.) TC6 is from the station made on the shelf in 200 m water depth. This station represents the 'pure' Brazil Current. All flow is directed towards the south-west with speeds decreasing from 50 cm s^{-1} at the surface to 35 cm s^{-1} near the bottom. Ship drift records and navigational charts (from the US Navy Hydrographic Office) indicate that this flow may extend over the entire shelf at comparable speeds.

Data from sites TC1 and TC7 near the seamounts are more difficult to interpret because of the possible influence of the bottom topography. However, both sites show southward surface flow, northward flow of Intermediate Water and southward flow of Deep Water. Note that these data are based on a single profile, not the average of three like those at TC2–TC6. TC1 was revisited at the end of the cruise and speeds were smaller and somewhat rotated from those in Fig. 1. (Surface flow was more westerly and 800 m flow more northerly.) The general sense of the flow of the water masses was, however, the same. All of these profiles support Wüst's mass analysis indicating flow away from known sources, in contrast to the more recent[11,12] view for the Intermediate Water. Note, however, that these measurements do not preclude the possibility that Intermediate Water is transported towards the west, south of 24° S and then turns equatorward. The significance of the direct measurements for dynamic computations is striking. For example, a choice of 900 m as a reference level at TC5 would yield southward surface speeds of 70 cm s^{-1} (twice the observed) and the wrong direction for the Intermediate Water. Thus charts of dynamic topography relative to 1,000 m may be inappropriate for the study of the Brazil Current at 24° S and attention should be paid to the distinct water mass characteristics.

Using these observations to estimate the transport of the Brazil Current down to 400 m yields $\sim 6 \times 10^6$ m^3 s^{-1} towards the south offshore of the 200-m isobath. If TC6 is representative of the flow on the shelf, another 5×10^6 m^3 s^{-1} may flow inshore of the 200-m isobath. Indeed, using the historical T–S relation for the area[14], geostrophic transport computed from temperatures measured by Pegasus is $\sim 5.5 \times 10^6$ m^3 s^{-1} relative to 400 m. While the total transport (11×10^6 m^3 s^{-1}) may not then be significantly different from earlier estimates, its vertical distribution is quite dissimilar in being confined to the upper 400 m. Estimates of the poleward heat flux will also differ due to the higher mean temperature of the water moving towards the pole—an effect which is enhanced by the strong equatorward flow of cooler Antarctic Intermediate Water

This work was supported in part by NSF grant OCE82-14834 L. Miranda and A Mascarenhas provided valuable assistance in collecting the data. Logistical support from the University of Sao Paulo was essential to the field programme.

The Somali Current in autumn 1984, before the onset of the north-east monsoon

Friedrich Schott* & Michele Fieux†

* Rosenstiel School of Marine and Atmospheric Science, University of Miami, Miami, Florida 33149, USA
† Laboratoire d'Océanographie Physique du Muséum National d'Histoire Naturelle, 75231 Paris, France

The Somali Current undergoes vigorous variations during the course of the south-west monsoon. Although the initial phases of this response were fairly intensively studied during the FGGE Indian Ocean Experiment (INDEX) in 1979[1,2], relatively little is known about what happens in the late summer monsoon and the transition to the winter monsoon. In October 1984, we carried out measurements in the Somali Current regime with a shipboard acoustic Doppler current profiler which showed that a continuous Somali Current did not exist at this time: instead, the cross-equatorial flow with a transport of 12×10^6 m^3 s^{-1} in the upper 100 m identified by relatively low surface salinities, was found to turn offshore south of 2° N. Between 6 and 11° N, a large closed anticyclonic gyre, marked by relatively high surface salinities, was found with a transport of 32×10^6 m^3 s^{-1} in the upper 250 m, which is significantly greater than previously estimated from geostrophic calculations.

In the initial response to the onset of the south-west monsoon, from early May to early June, the Somali Current develops as a shallow cross-equatorial current, turning offshore at about 3° N with a cold upwelling wedge at the turnoff latitude, after the onset of the strong wind stress curl off Somalia in mid-June, a second gyre is generated between 5 and 10° N with a second cold wedge at the coast on its northern end Satellite sea-surface temperature and ship measurements indicate that at some time between late July and September the southern cold wedge starts to propagate northward and the two-gyre pattern seems to collapse[2,3] Ship measurements in different years showed that the water behind the northward-travelling southern cold wedge was low-saline water originating south of the Equator, replacing the higher-saline water found between 5 and 10° N in May to July[2,4,5]. The result of this development is that in the late summer monsoon, the Somali Current is a continuous boundary current from south of the Equator to the Horn of Africa. It is not known in any detail what happens in the transition period between the decay of the south-west monsoon in late August and the onset of the winter monsoon in early November

Nothing is known about the cross-equatorial flow at this time, partly because geostrophy cannot be applied close to the Equator to calculate transports from hydrographical data For the northern Somali Current region, expendable bathythermograph (XBT) measurements (for example, refs 6, 7) suggest that a northern gyre continues in that period, but its water origin, current structure, transports and any relation of this gyre to the current further south are not really known.

During part of this transition period, from 17 to 22 October 1984, we performed measurements in the Somali Current system on board the French RV *Marion Dufresne* with a shipboard acoustic Doppler current profiler, XBTs and continuous surface-temperature and salinity recordings (Fig 1).

The cross-equatorial flow in the Somali Current in October 1984, as the surface-current vectors (Fig. 1*a*) and the surface salinities of 35 0–35 2‰ (Fig. 1*b*) indicate, does not continue northward but turns offshore south of about 2° N Its origin is the South Equatorial Current, the biggest branch of which forms a northward-flowing boundary current east of Madagascar, which then continues westward around the northern tip of Madagascar across to Africa, where it is called the East African Coast Current Through admixtures of the low-saline coastal waters from East African rivers, the surface salinity is slightly reduced relative to that of the inflowing South Equatorial Current

The northward current component through the equatorial section (Fig 2*b*) has a subsurface maximum of more than 150 cm s^{-1} near the coast at about 40 m depth and still velocities of more than 50 cm s^{-1} at 200 m depth The northward transport through that section in the upper 100 m is 12.3×10^6 m^3 s^{-1}, which is almost exactly matched by the transport turning offshore in the top 100 m between 2° N and the Equator, for which we found 12.6×10^6 m^3 s^{-1} from the acoustic velocity-profile measurements The cross-equatorial transport in the upper 100 m is comparable to the transports determined by Leetmaa *et al.*[1] during five repetitions of a transport section normal to the coast at 1° S in the period May–June 1979, for which they obtained a mean transport of 14.0×10^6 m^3 s^{-1}. Even the northward flow in the depth range 100–300 m for which we obtained 8.4×10^6 m^3 s^{-1} (the quality of the acoustic current-profile data deteriorates below ~ 250 m) is comparable in magnitude to that of the 1979 early-summer measurements which showed a mean of 6.0×10^6 m^3 s^{-1} (ref. 1). In summary, the cross-equatorial transport of the Somali Current in late autumn is very similar to that during the onset of the south-west monsoon. The local winds off Kenya/Somalia are quite different during May/June and October (Fig. 1*c*), whereas the trade winds over the subtropical south Indian Ocean are quite similar in these two phases, which suggests that the cross-equatorial flow in the early phase of the south-west monsoon is driven primarily by remote forcing through the inflow from the South Equatorial Current, not by the local monsoon winds off East Africa.

North of 6° N, the ship-drift vectors (Fig 1*a*) indicate a large anticyclonic gyre, which had surface salinities of 35.6–35.8 parts per thousand (p.p.t) (Fig. 1*b*), that is, significantly higher than in the cross-equatorial current. Similar salinity differences between cross-equatorial flow and the northern regime along that longitude were found in earlier autumn cruises with the *Marion Dufresne*[8]. The current in the northern branch of this gyre was surface intensified (Fig. 2*a*) despite the lack of strong local winds during that time (Fig. 1*c*). Transport of this gyre in the upper 250 m was 33.5×10^6 m^3 s^{-1} westward between 6° and

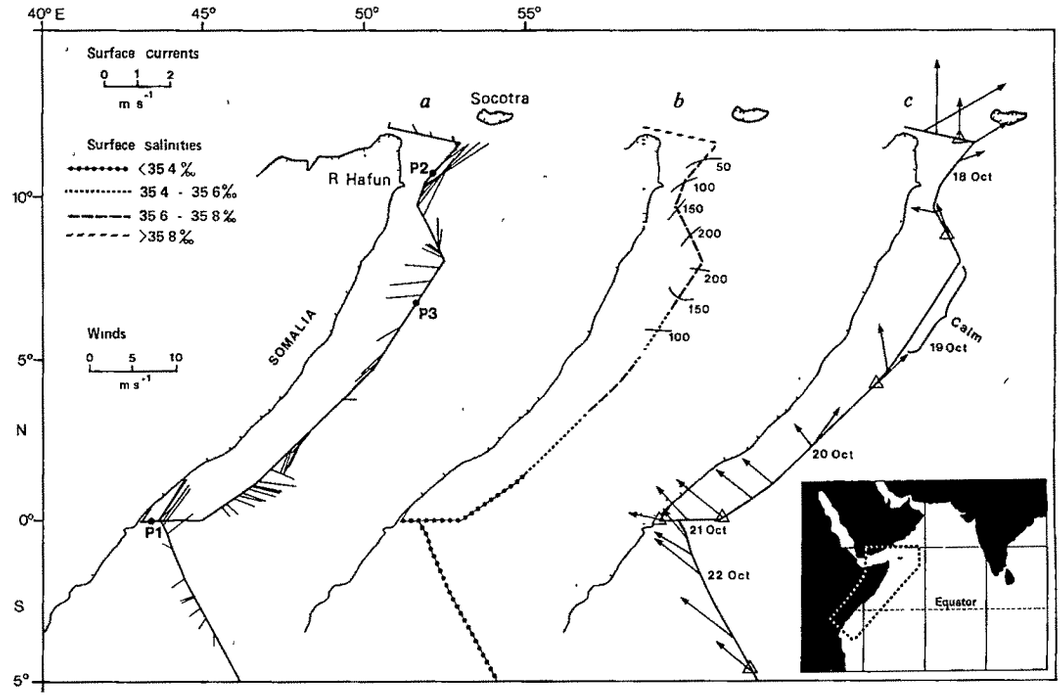

Fig. 1 Measurements along the track of RV *Marion Dufresne* during 18–22 October 1984 The Doppler profiler is an Ametek-Straze Model DCP 4400 operating at 115 kHz. Good data were obtained down to about 250 m depth or more at quiet to moderate sea state. Data storage at sea was in averages of 10 profiles at a time interval of 32 s for the averages. Subsequently, for the purpose of transport calculation, data were averaged to 15-min profiles, that is, over 280 individual profiles. In earlier comparisons in the Florida Current with other direct current measurements, we had determined that for sample sizes of this magnitude the accuracy of the acoustically measured horizontal currents, relative to the ship, was a few centimetres per second. The ship's motion was determined using satellite positioning. *a*, Drift vectors (P1–P3, locations of profiles shown in Fig. 2*a*) determined from the ship's satellite navigation system and the two-component electromagnetic speed log. However, satellite passes occur irregularly and gaps of several hours between fixes actually occurred in that region. Although this is unsatisfactory for calibration of individual profiles, it may be sufficient for the total transport through some section, say the equatorial section of the ship track, because for that calculation only the positions at both ends of the section need to be known. This means that the longer the section, the less the importance of position inaccuracies. *b*, Surface salinities and depth of 20 °C isotherm north of 5° N. *c*, Wind vectors, also indicating midnight ship positions (△, 00Z positions). Inset (lower right) shows area of observations off north-east Africa.

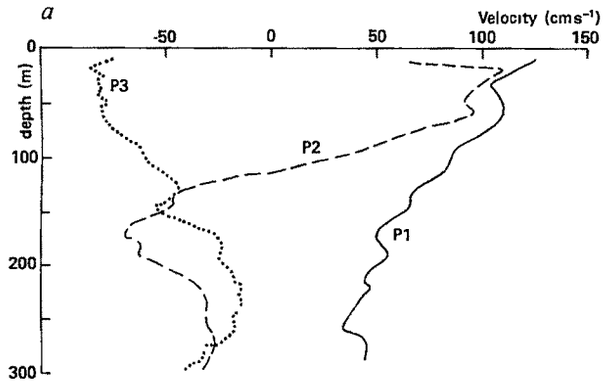

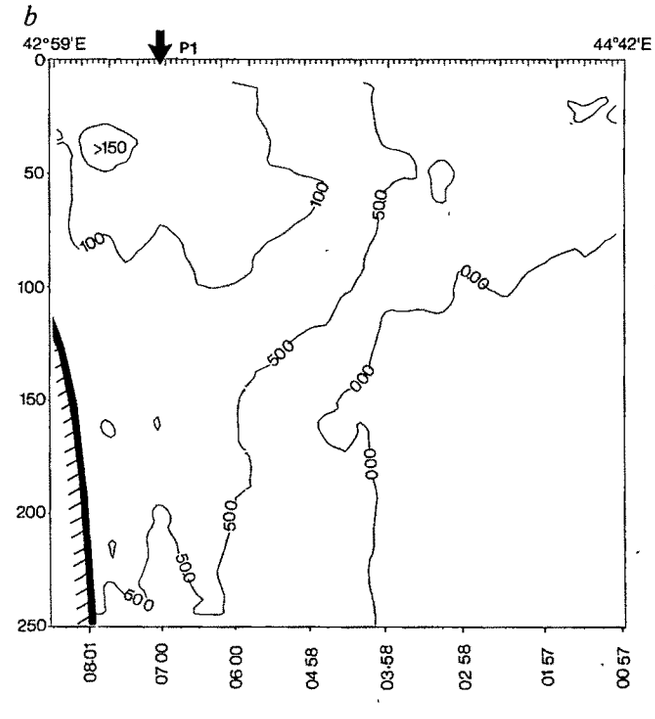

Fig. 2 *a*, Profiles of north component of current at point P1 (0°02′N, 43° 19′E) in cross-equatorial flow and of east components at points P2 (10° 40′ N, 52° 04′ E) and P3 (6°43′N, 51°30′E) in the northern gyre (Fig. 1*a*). *b*, Section of the northward current component along the Equator (for location, see Fig 1*a*) for 21 October 1984 (start 00:57·05; stop 08:45·40)

8.5° N as determined from the acoustic Doppler current profiles, and 31.6×10^6 m^3 s^{-1} eastward between 8.5° and 11.5° N. This is a closed mass budget within a few per cent. This is surprising because it has to be kept in mind that these transport numbers can be significantly affected by a small misalignment of the horizontal axis of the acoustic transducer. We corrected for the misalignment by comparing the vectors from satellite and radar navigation with those from acoustic bottom tracking near the coast, but an error of several 10^6 m^3 s^{-1} is still possible when integrating over long track segments as done here. It appears though, from the good balance both in the northern gyre and the cross-equatorial flow, that the compensation was effective. Earlier geostrophic transport calculations[7] obtained 22×10^6 m^3 s^{-1} in the 0–400-m layer for an XBT section in October, from which densities and geostrophic currents were derived using a mean temperature/salinity relation. When applying the same method[7] to our XBT data, we obtain 17×10^6 m^3 s^{-1}, both significantly lower than our direct measurements for just the upper 250 m. One reason for the difference is that the current at the assumed reference level of 400 m is not zero; another reason is that there is significant deviation from plain geostrophy through the curvature term.

Current profiles in the eastward- and westward-flowing branches of the northern gyre (Fig. 2*a*) show that the northern gyre is not symmetrical, which is also obvious from the ship drifts (Fig. 1*a*) and the depths of the 20 °C isotherms (Fig. 1*b*).

This asymmetry, which is typical and also is visible in earlier XBT sections through the northern gyre[6,7], can be explained by the strong nonlinearity of that circulation system, which causes a shift of high currents into the northwestern corner (for example, ref. 9.)

As mentioned earlier, the Somali Current seems usually to go through a phase (in August–September after the collapse of the two-gyre system where the Somali Current is a continuous boundary current) of carrying low-saline water from south of the Equator to ~10° N[2,4,5]. If this situation also occurred in 1984, we conclude from our observations that the current of low-saline water must retract again in late September–mid-October. Where, then, is all the low-saline water which was found all the way up to Ras Hafun in ~200-m-thick layer between the coast and ~300 km offshore in late August in these earlier studies? The transport of this water was estimated at 13×10^6 m^3 s^{-1} by Schott[10], about equivalent to the cross-equatorial transport found in the early south-west monsoon phase by Leetmaa *et al.*[1]. Another possibility is that in 1984 the two-gyre pattern did not collapse during August/September but remained intact from June to October. It is not known whether this can actually happen, but the possibility will be investigated using satellite surface-temperature data.

It is interesting that only very small currents were observed between Socotra and Cap Guardafui (Fig. 1*a*). This is at variance with recent numerical model results of Luther and O'Brien[11] and G. Philander (personal communication), who, although using quite different models, both show the northern gyre to propagate further northward and to circulate around Socotra in mid-October, that is, with its full transport through the passage between Socotra and the mainland.

A technical conclusion from this first application of the Ametek Doppler profiler in the Indian Ocean is that the system has provided very useful data of the near-surface circulation, which could not be easily obtained by any other means.

We thank the Terres Australes et Antarctiques Francaises (TAAF) for having made this cruise possible and the captain and crew of RV *Marion Dufresne* for their enthusiasm and help with the shipboard work. We also thank P. Bedard, A Kartavtseff, B. Olivier and G. Samuels for help in acquisition and processing of the data. This study was supported by the Office of Naval Research under contract N-00014-80C-0042.

Determination of the age of the Australian continent by single-grain zircon analysis of Mt Narryer metaquartzite

Urs Schärer* & Claude J. Allègre

Laboratoire de Géochimie et Cosmochimie, Institut de Physique du Globe et Département des Sciences de la Terre, Universités Paris VI et VII, 4 Place Jussieu, 75230 Paris Cedex 05, France

A fundamental constraint on the evolution of the Earth is the time of the first occurrence of continental crust. The recent publication[1] of ages of 4,200–4,100 Myr for zircons from Australia is therefore of considerable importance. This dating was achieved by single-grain analysis on the SHRIMP ion microprobe at the Australian National University. To substantiate the existence of these old zircons by an alternative method, we studied the same zircon population by conventional solid-source mass spectrometry and isotope dilution analysis of single grains and individual fragments of single grains. Our results confirm neither the 4,200–4,100-Myr ages nor the particular discordancy patterns obtained on the ion probe. The age pattern we obtained can be explained by zircon crystallization 3,800–3,300 Myr ago. Probable primary ages of ~3,750–3,600 Myr coincide with model Sm/Nd ages for the adjacent gneisses[2], the possible source rocks of the Mt Narryer quartzite, and the younger ages are interpreted as those of zircon overgrowth compatible with a Rb/Sr age for the regional metamorphic overprint[2].

In their ion-probe study, Froude *et al.*[1] detected, among the 20 precisely analysed grains, 4 grains with apparent minimum ages older than 4,000 Myr, whereas the others yielded minimum ages between about 3,100 and 3,750 Myr. However, the data for the latter have not yet been published, which precludes a direct comparison with the results presented here. We have analysed 27 single zircon grains and 12 individual fragments of another 5 single grains. Comments on the isotope dilution technique are given in the footnotes to Table 1, which lists the U/Pb analytical data in order of decreasing U/Pb ages. Such high-resolution analyses have been shown to be very useful for deciphering complex zircon populations in igneous and metamorphic rocks (for example, refs 3, 4) and elucidating the age spectrum (provenance ages) of detrital zircons[5,6]. The analysis of fragments of single grains enables us to determine intra-grain ages[7]. Figure 1 shows the location of the sample and indicates previous model Sm/Nd ages[2] from the adjacent gneisses as well as a Rb/Sr age[2], interpreted as dating high-grade metamorphism in the gneisses.

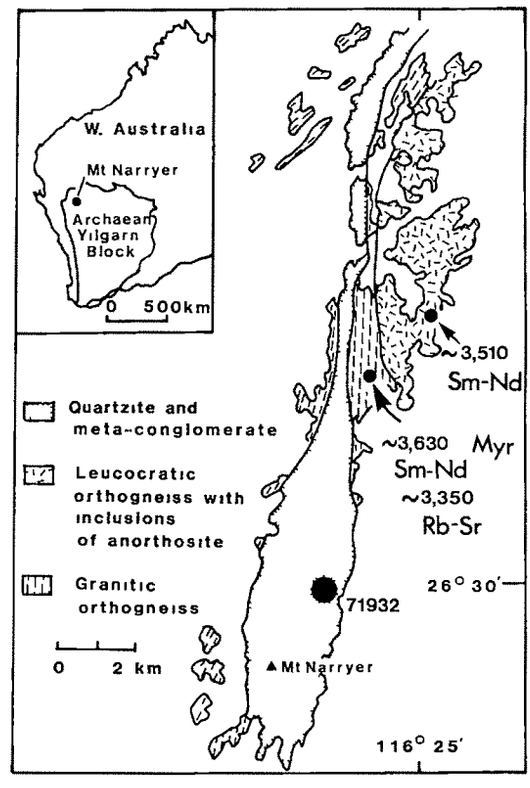

Fig. 1 Geological sketch map (slightly simplified, after ref. 1) with sample locality and previous model Sm/Nd and Rb/Sr ages[2] for gneisses adjacent to the quartzite.

Types A, B, C, D correspond to the shape characteristics given in Fig 2*b* The constants used are $1\,55125\times10^{-10}\,yr^{-1}$ for $\lambda\,^{238}U$ (ref 15), $9\,8485\times10^{-10}\,yr^{-1}$ for $\lambda\,^{235}U$ (ref 15) and 137 88 for $^{238}U/^{235}U$ (ref 16) Zircons were dissolved in Teflon bombs[17] in 50% HF during ~100 h at 220 °C Element separation and purification were performed as described earlier[18] The isotope ratios and amounts were determined by isotope dilution analyses in a Thomson THN 206 mass spectrometer using a $^{205}Pb/^{235}U$ mixed tracer Both elements were loaded with H_3PO_4 and silica gel on Re single filaments The isotope composition of blank Pb was determined to be 17 84±0 10 (2σ error) for $^{206}Pb/^{204}Pb$, 15 53±0 08 for $^{207}Pb/^{204}Pb$ and 37 41±0 21 for $^{208}Pb/^{204}Pb$ The total Pb blank was $30\pm15\times10^{-12}$ g ($5\text{–}10\times10^{-12}$ g from the chemical procedure and $10\text{–}35\times10^{-12}$ g extracted from the Teflon bombs) The total blank for U was $<10\times10^{-12}$ g with an average of $\sim5\times10^{-12}$ g The maximum errors on the isotope ratios are 0 5% for $^{206}Pb/^{238}U$ and $^{207}Pb/^{206}Pb$ and 0 7% for $^{207}Pb/^{235}U$ These errors take into account (1) the precision of the mass spectrometric measurements, (2) the uncertainties in the isotope composition and amount of blank Pb, (3) the correction for ^{205}Tl interference, (4) the uncertainty of mass-discrimination corrections and (5) the accuracy of tracer calibration

* Absolute amount of U in the sample, corrected for 5×10^{-12} g U blank

† Absolute amount of radiogenic Pb in the sample, corrected for 30×10^{-12} g blank Pb and, where detectable, corrected also for incorporated common Pb (Pb_c) with the following isotope composition 11 83 for $^{208}Pb/^{204}Pb$, 13 87 for $^{207}Pb/^{204}Pb$ and 31 67 for $^{208}Pb/^{204}Pb$ This isotope composition corresponds to a 3,630 Myr BP Pb that evolved from 4,550 Myr BP with a $^{238}U/^{204}Pb$ of 9 3, a $^{232}Th/^{204}Pb$ of 39 1 and a primordial isotope composition identical to the Canyon Diablo meteorite[19], further comments on Pb_c in zircon are given in the text

‡ Absolute amount of Pb_c in the sample

§ No incorporated Pb_c detectable in the sample (total amount of Pb_c in the analyses was $<45\times10^{-12}$ g)

Figure 2*a* is a summary Concordia diagram[8] of single-grain and fragment analyses together with the ion-probe data for the apparently 4,100–4,200-Myr BP grains and Fig. 2*b* shows a more detailed Concordia diagram with a broad grouping of the different zircon types and a distinction between single-grain and individual fragment data Additionally, Fig. 2*b* indicates the upper intercept ages of the regression lines through distinct fragments of single grains (intra-grain ages).

All zircons analysed grain-by-grain were chosen by their habit, colour, degree of transparency, size and particular features such as pronounced core–rim zoning. Those from which the fragments were broken were selected to cover the whole range of different grain types Because Froude *et al.*[1] indicated that the apparently 4,100–4,200-Myr zircons are distinguished by their peculiar angular form and the absence of inclusions, we first investigated perfectly euhedral grains with sharp edges, high transparency (to avoid inclusions) and uncorroded surfaces However, we mention that the grain illustrated for reference in a photomicrograph in Froude *et al.*[1] resembles more a simple piece of broken zircon than a particular angular type Nevertheless, we analysed in a first group of zircons (see Fig. 2*b*) the series of grains that most closely fulfilled the above conditions, followed by a second group (Fig. 2*b*) similar to the first but with much lower degrees of transparency. In a third group we investigated transparent and translucent grains with strongly rounded edges, some of which had significant surface corrosion features. As a last group with distinct grain type, a series of particularly milky translucent zircons was analysed, most of them exhibiting clearly visible zoning between the inner and outer parts of the crystal. This latter feature suggests that some of the zircons grow in two stages

Despite the wide range of grain characteristics, all zircons yield similarly discordant age patterns (Fig 2*a*, *b*) with minimum ages ranging from 2,750 to 3,600 Myr (Table 1), plotting in a data field that intersects the Concordia curve along a sector from ~3,400 to 3,700 Myr. This suggests that the primary ages of the zircons lie in this interval, but because none of the different groups of zircons defines a simple linear array, we cannot distinguish cogenetic zircon populations and, thus, no precise primary ages can be determined.

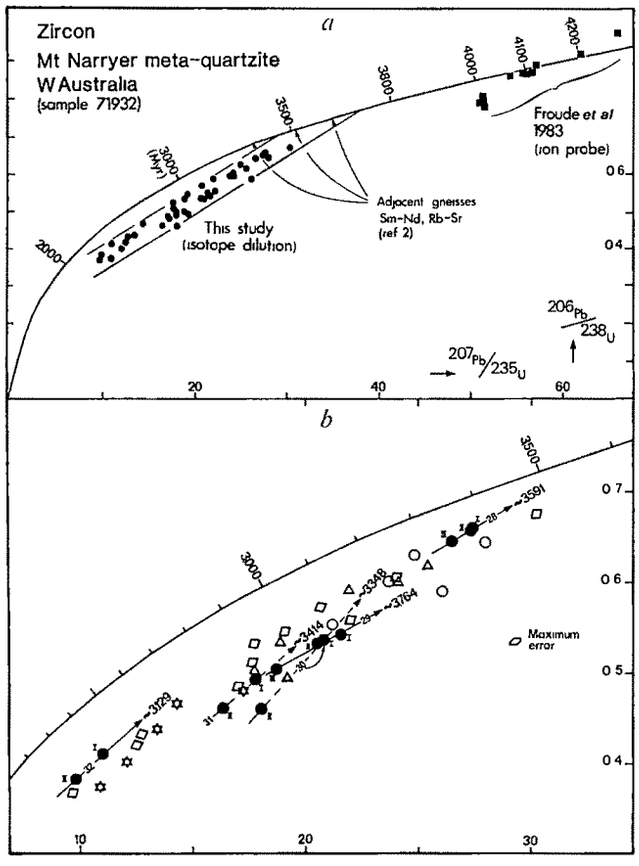

Fig. 2 Concordia diagram of the U/Pb analytical results *a*, Summary diagram of single-grain and fragment analyses compared with ion-probe data[1] for the apparently 4,100–4,200-Myr BP zircons; *b*, detailed diagram showing distinctions between different grain types and single-grain versus fragment analyses. Single zircon grains □, Sharp-edged transparent grains; △, sharp-edged translucent grains; ○, strongly edge-rounded transparent and translucent grains, ☆, milky translucent grains with core–rim zoning; ●, single fragments (from grains 28–32)

A few observations concerning the grain-by-grain analysis may be emphasized: the particularly milky translucent grains yield younger ages than most of the other grain types, plotting in the lowest segment of the discordancy field (Fig. 2*b*). Moreover, these milky grains are, together with some other highly discordant grains, characterized by especially large amounts of incorporated common lead (Pb_c, Table 1), contributing $\leq 15\%$ of total lead in the crystal. This positive correlation between Pb_c content and degree of discordancy supports an earlier conclusion[7] that loss of radiogenic lead may occur by exchange with Pb_c from intergranular phases. The presence of such incorporated Pb_c, also observed to a smaller extent in less discordant grains, requires a correction which necessarily affects the apparent ages of all Pb_c-bearing grains. We performed this correction by assuming the incorporated Pb_c to be on average ~3,630 Myr old, as suggested by the minimum ages of Pb_c-free grains ranging up to ~3,600 Myr, and supported by the model Sm/Nd ages[2] for the adjacent gneisses, the possible source rocks of the quartzite. In the case of sediments, the isotope composition of this incorporated common lead cannot be determined directly because of the lack of Pb-rich/U-deficient cogenetic minerals such as K-feldspar. Therefore, the above assumption is necessary. However, a correction with a significantly younger lead (for example, a 3,350-Myr-old Pb_c) (probable age of metamorphism in the quartzite) would only cause age differences lying within the maximum error of our analytical technique (Table 1, Fig. 2*b*). A correction with a 4,100-Myr-old Pb would influence a few data by 2%, whereas most of the single-grain data would be changed by <1%. This shows that variations in the isotope composition of incorporated Pb_c, relative to the 3,300–4,100-Myr age range, modify the data only to a small extent; even a correction with present-day Pb_c (for example, blank Pb_c, Table 1) would not shift any of the data to ages older than 3,700 Myr.

Our results from the single-grain analyses confirm neither the existence of 4,100–4,200-Myr-old zircons in this sample nor the particular discordancy patterns observed on the ion probe[1]. The discordancy arrays of the ion-probe data all point to the origin of the Concordia curve (zero ages), suggesting recent Pb loss (or U gain) of these zircons (see Fig. 2*a* and ref. 1). Here, we do not show any evidence in favour of such recent perturbation of the U/Pb systems; the lower extrapolation of our discordancy field for all single-grain data intersects the Concordia curve along a sector from ~1,400 to 2,000 Myr, substantiating Pb to be ancient. Moreover, none of our grains yield a result that plots above the Concordia curve as reported for the ion-probe analyses for both apparently 4,100-Myr-old and significantly younger zircons (see Fig. 2*a* and ref. 1).

Because of the discrepancy between the isotope dilution and the ion-probe data, we extended our investigation to analyses of individual fragments of single grains, for two main purposes: (1) to assess whether distinct parts of grains preserved a record of zircon growth before 4,000 Myr BP and (2) to obtain intra-grain ages, which approximate primary zircon ages better than those of arrays of single, and not necessarily cogenetic, zircon grains. Hence, we broke up five zircons representative of the different grain types observed in the quartzite (Fig. 2*b*).

A typical grain of the first group (grain 28), a sharp-edged transparent zircon, was broken into three fragments (I, II, III, Fig. 2*b*, Table 1), where I represents the middle part of this long prismatic grain and II and III the two prismatic ends. The regression line[9] through the fragments (calculated using the individual errors of the fragment analyses) intercepts the Concordia curve at ~3,591 Myr, which is in agreement with the model Sm/Nd age for the possible source rocks of the quartzite. Three fragments of another grain (grain 29), a sharp-edged but translucent zircon (second group in Fig. 2*b*), define an intercept age of ~3,764 Myr. As for grain 28, the central part of the long prismatic zircon (fragment I) is the oldest, suggesting that loss of radiogenic Pb is favoured in the pyramidal ends of the grain either because of crystallographic differences between middle and outer parts or simply because of the higher surface/volume ratio of the pyramidal ends. A third grain (grain 30), a particularly milky translucent and core–rim-zoned zircon (fourth group in Fig. 2*b*), has been analysed in two fragments (I and II) where I consisted mainly of rim material, whereas II was dominated by material from the core of the grain. The two fragments define a line with an intercept age of ~3,348 Myr, which is identical to the probable age of high-grade metamorphism, in the adjacent gneisses[2]. To account for this age coincidence as well as the fact that grain 30 was core–rim zoned, it seems plausible that the intercept age dates zircon overgrowth (that is, new growth) during regional metamorphism, which is recognized clearly in the quartzite[10]. This interpretation seems to be supported by the discordancy trend for single grains of milky zoned zircons (Fig. 2*b*), which points to significantly younger ages than the arrays of most other zircons. A further zircon of the first group (grain 31), a transparent sharp-edged homogeneous grain, broken in two approximately equal fragments, yields an intercept age of ~3,414 Myr, suggesting that some of the smaller grains represent entirely new-grown zircons during high-grade metamorphism. A final zircon, broken in two fragments (grain 32), was a peculiar green milky translucent grain yielding an intercept age of ~3,129 Myr. This age suggests the existence of a second younger metamorphic event in the quartzite. However, the line through the two fragments is too poorly defined to define the intercept age with any confidence and, moreover, no such event is known in the area.

Thus, individual fragments from single grains representing the different crystal types in the quartzite also do not yield any evidence for zircons older than 3,800 Myr. Furthermore, the discordancy trends of the ~3,600–3,800-Myr BP fragments

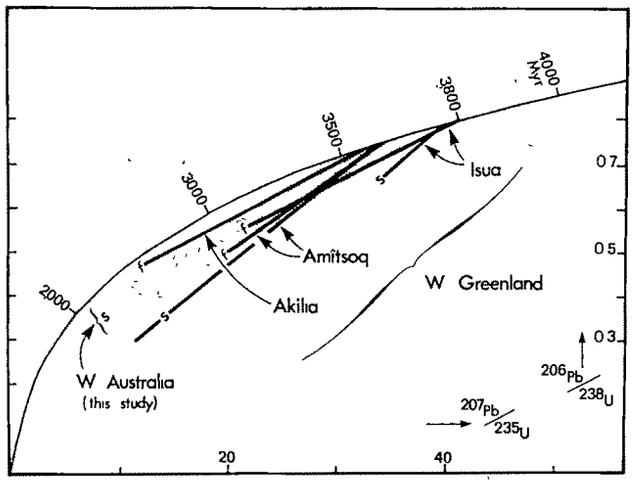

Fig. 3 Summary Concordia diagram including the Australian Mt Narryer quartzite zircons analysed here and, for comparison, zircons from Western Greenland, specifically from the Isua supracrustals[12,13], the Amîtsoq gneisses[12-14] and the Akilia association[13]. All ages have been calculated using the new uranium decay constants[15], f, fractions, s, single grains

(grains 28 and 29) are identical to those for the single zircon grains, again contrary to the discordancy patterns obtained on the ion probe[1]. The question remains as to whether the lack of 4,100–4,200-Myr BP zircons found here is an artefact of grain selection, that is, that we have not chosen the correct crystals. This possibility cannot be completely eliminated. Furthermore, there is an independent argument to be considered. the single grains and individual fragments analysed here yield clearly discordant ages, proving that all zircons were open systems for Pb either during a distinct period or continuously. This contrasts strongly with the apparently concordant ages of the 4,100–4,200-Myr BP zircons identified by the ion-probe technique. Such closed-system behaviour of the 4,100–4,200 Myr BP zircons, which would necessarily have a higher degree of radioactive damage than the younger ones, is difficult to explain. Closed-system behaviour would be particularly surprising given that the quartzite from which the zircons have been extracted suffered high-grade metamorphism probably ~3,400 Myr ago; in general, even low-grade metamorphism, for example, under lower greenschist facies conditions, produces significant Pb loss in detrital zircons (for example, ref. 11).

In conclusion, we emphasize that the complete data set for single grains and fragments can be explained by zircon growth between 3,300 and 3,800 Myr BP. The upper intercept ages of both the overall discordancy field and two of the intra-grain arrays point to primary ages of the order of 3,600–3,800 Myr. Because the quartzite has been affected by high-grade metamorphism, probably ~3,400 Myr ago, these upper intercept ages may be slightly too young relative to the real crystallization ages of zircon, because of an early Pb loss during metamorphism. From this point of view, the possibility that parts of the Australian continent are older than 3,800 Myr cannot be excluded completely. However, the present study does not produce any evidence in support of this idea. On the other hand, the zircon ages reported here show the Australian continent to contain crustal rocks 3,600–3,800 Myr in age, analogous to those in Greenland. This similarity is illustrated in Fig. 3, which is a summary Concordia diagram including all reliable zircon ages from Western Greenland (Isua, Amîtsoq and Akilia; refs 12–14) together with our data from the Mt Narryer quartzite. The overlap between possible primary ages and discordancy arrays of the Australian and Greenland zircons is consistent with the hypothesis that both cratons in the present-day Northern and Southern Hemisphere developed from a continental nucleus that grew ~3,600–3,800 Myr ago.

We thank Dr W. Compston for providing the zircons in which the 4,100–4,200-Myr-old grains were identified (sample GWSA 71932) and S. H. Richardson and G. Manhes for critical reading of the manuscript. This is Institut de Physique du Globe contribution 813.

Halomethane from halide ion—a highly efficient fungal conversion of environmental significance

David B. Harper

Department of Agricultural and Food Chemistry,
The Queen's University of Belfast, and
Agricultural and Food Chemistry Research Division, Department of Agriculture for Northern Ireland, Newforge Lane,
Belfast BT9 5PX, UK

Globally, at least 5 Mt yr^{-1} of chloromethane (CH_3Cl) must originate from natural sources, according to estimates based on environmental concentrations, man-made emissions of 26 kt yr^{-1} being insignificant in comparison[1-3]. Although CH_3Cl is a natural product of several fungal species[4,5], no quantitative investigations of its biological production have been reported. We have measured CH_3Cl production by a common wood-rotting fungus, and report that on glucose-based media, the chloride ion (Cl^-) at concentrations <4 mM was methylated with >90% efficiency. The pattern of CH_3Cl biogenesis was typical of a secondary metabolite and paralleled loss of Cl^- from the medium. With cellulosic substrates, CH_3Cl yields ranged between 80 and 95% at Cl^- concentrations as high as 25 mM, although production extended over a longer period. Bromo- and iodomethane were formed in high yield from the corresponding halide ions. Such high-efficiency methylation of the halide ion indicates that fungi could make a substantial contribution to the atmospheric CH_3Cl burden.

Assessments of CH_3Cl production were made during growth of *Phellinus pomaceus* (Pers.) syn. *Fomes pomaceus* (Forest Products Research Laboratory no. 33A), a white-rot fungus of worldwide distribution reported to synthesize CH_3Cl (ref. 4). When the fungus was grown with glucose as the main carbon source, CH_3Cl production was clearly confined (Fig. 1) to the period after exponential growth and before autolysis, a pattern characteristic of secondary metabolites, the formation of which is usually retarded until the trophophase approaches completion[6,7]. Whereas fungal growth continued for ~10 days, CH_3Cl biosynthesis extended for another 8 days. Chloride uptake from the medium closely paralleled CH_3Cl biogenesis, showing that there was little accumulation of Cl^- in the mycelium before CH_3Cl release, a conclusion confirmed by determination of Cl^- content in the mycelium after ashing at various stages of growth. Chloromethane yield, expressed as a

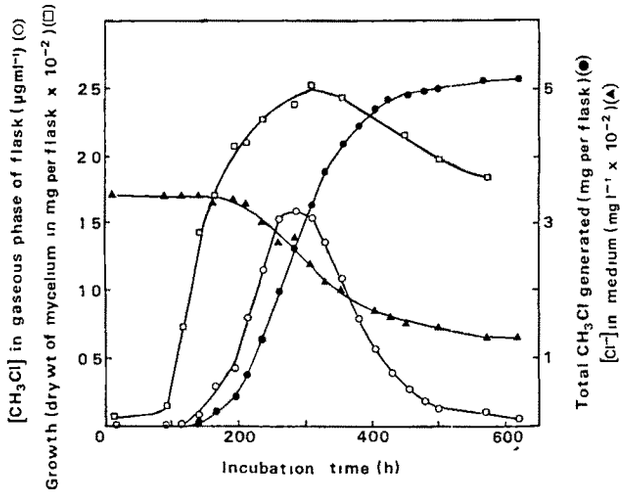

Fig. 1 Growth of *P. pomaceus* on glucose-based medium containing 9.6 mM NaCl in relation to CH_3Cl production and chloride loss from the medium. Results are expressed as follows: □, growth measured as mycelial dry wt; ○, CH_3Cl concentration in gaseous phase in the culture flask, ●, total CH_3Cl generated per culture flask; ▲, chloride ion concentration in the culture medium.

Methods. Cultures of *P. pomaceus* were grown on a solid medium *p*H 6.5 (20 ml) containing ($g\,l^{-1}$): glucose, 30; mycological peptone, 5, agarose '10' (BDH), 10; NaCl, 0.5 in conical flasks (25 × 250 ml) at 25 °C. As a precaution against bacterial contamination, chloramphenicol (25 mg l^{-1}) was also added to the medium, experiments having indicated that the presence of the compound did not affect production of CH_3Cl or chloride levels in the medium during growth. The inoculum, which was spread uniformly over the surface of the medium, was a mycelial suspension (1 ml) prepared by homogenizing mycelium (600 mg wet wt) in sterile distilled water (20 ml) for 30 s with an Ultra Turrax homogenizer. The mycelium used for inoculation was grown on 5% malt extract agar containing not more than 1 mM chloride. Each conical flask was provided with a polytetrafluoroethylene (PTFE)-coated rubber bung through which passed a glass tube (10 cm × 0.8 cm internal diameter, i.d.) packed uniformly with cotton wool and fitted so that the lower end was flush with the lower surface of the stopper. The bung was also equipped with a sampling port comprising a glass tube of 1 mm i.d. projecting 0.5 cm into the interior of the flask and flared at the upper end protruding from the stopper so as to accommodate a small PTFE-coated rubber bung. CH_3Cl production during growth was assessed by a modification of a headspace technique described previously[14]. Initially, to calibrate the system, the rate of loss of gaseous halomethane from flasks equipped with outlet tubes as above was measured by introducing aqueous solutions of halomethane (20 ml) and determining headspace concentrations (by gas chromatography with a flame ionization detector) of aliquots (2 ml) withdrawn through the sampling port at intervals over 8 days. As diffusion of halomethane from the liquid to the gaseous phase within the flask was rapid compared with the rate of loss from the flask, the system could be regarded as single-phase in subsequent calculations. The loss rate obeyed first-order kinetics, the half-lives of chloro-, bromo- and iodomethanes being 13.8, 19.6 and 26.2 h respectively. Therefore, the total amount of halomethane generated by a fungal culture at any time during growth could be calculated from empirical measurements, at regular intervals, of the halomethane concentration in the flask headspace and the half-life of the halomethane using a computer integrating program[14]. Growth was measured as the dry wt of washed mycelium obtained by filtration of the agarose medium after solution in hot water. Chloride ion concentrations were determined on the diluted medium with a Corning Eel 921 chloride meter.

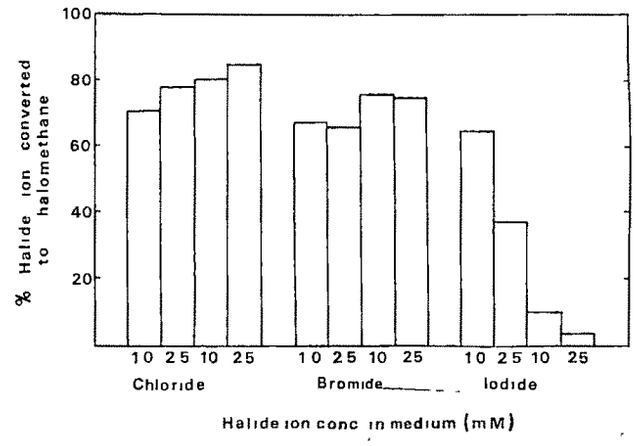

Fig. 2 Effect of halide ion concentration on yield of corresponding halomethane for *P. pomaceus* grown on cellulose as main carbon source.

Methods. Cultures of *P. pomaceus* were grown in conical flasks (in the conditions described in Fig. 1 legend) on filter paper (Whatman No. 540) (6.9 g) augmented with a chloride-free mineral salts medium of *p*H 6.5 (20 ml) containing pure L-amino acids (3.6 $g\,l^{-1}$) in similar proportions to those in mycological peptone and thiamine mononitrate (1.2 mg l^{-1}). The medium was supplemented with 1–25 mM NaCl, NaBr or NaI, as indicated. The results shown are the mean of duplicate treatments.

percentage of the Cl^- originally present in the medium, varied between 90 and 100% for Cl^- concentrations <4 mM, falling to 6% at 170 mM Cl^-. Between 1 and 170 mM Cl^-, total CH_3Cl production was linearly related to the logarithm of Cl^- concentration, although slight deviation occurred at the higher end of the concentration range.

As the fruiting bodies of *P. pomaceus* are typically found on trees of the Rosaceae, especially *Prunus*, CH_3Cl yields were assessed when the fungus was cultured with supplemental NaCl (20 mM) on sawdust derived from the wood of *Prunus domestica*, the common plum. Chloromethane production with both wood and other cellulosic substrates (such as filter paper, microcrystalline cellulose, cotton wool and newspaper) as main carbon sources extended over long periods, from 4 weeks (cotton wool) to 6 months (wood) but yields of CH_3Cl were much higher than with glucose-based medium at similar chloride concentration, ranging from 86% (cotton wool) to 95% (newspaper).

Figure 2 illustrates the effect of different concentrations of halide ion on halomethane yield, with cellulose (filter paper) as the substrate. Both bromide and iodide acted as acceptors for the methylating system. In contrast, with glucose-based media, yields of both chloro- and bromomethane did not decline with increasing halide ion concentration; indeed, a slight trend in the reverse direction was discernible with Cl^-. The suppression of secondary metabolite production by glucose and other readily utilizable carbon sources has been noted in many studies on secondary metabolism[7]. Iodomethane production decreased with increasing iodide concentration but this is probably attributable to the manifestly detrimental effects of this ion on growth. When equimolar concentrations (5 mM) of chloride, bromide and iodide were present, the preferred substrate was iodide, the respective halomethanes being formed in the proportion 1:4:19.

The magnitude of CH_3Cl production in nature by fungi is difficult to estimate. Chloromethane has been identified as a volatile product of six *Fomes* species[4] and of *Agaricus bisporus*[5], the common mushroom. Future studies may reveal the presence of this biosynthetic ability in many more cellulose-degrading species growing on wood, litter and soil worldwide. The high affinity of the methylating system for Cl^- ensures that even when environmental Cl^- concentrations are low, appreciable quantities of CH_3Cl are generated. Thus, despite a concentration of only 34 mg kg^{-1} in *P. domestica* wood, yields of CH_3Cl when *P. pomaceus* was grown on the unsupplemented substrate were between 40 and 50%. However, wood-rotting fungi are not confined to such low-chloride environments, being capable of mycelial growth on many plant substrates under a broad range of environmental conditions. The normal Cl^- content of plant material varies from 200 to 10,000 mg per kg dry wt[8,9] and many terrestrial soils exhibit appreciable salinity. Growth of fungi possessing such a high-affinity methylating system in these

circumstances could lead to production of substantial quantities of CH_3Cl and must therefore be considered alongside other postulated sources of atmospheric CH_3Cl such as combustion of vegetation[10] and reaction of iodomethane with Cl^- in sea water[11]. That such a biological source may be a major contributor to atmospheric CH_3Cl levels is of considerable interest in view of the importance ascribed to CH_3Cl and other man-made halocarbons in controlling the levels of stratospheric ozone[1,12]. Quite apart from the environmental significance, the enzymatic incorporation of halide ion apparently directly into a one-carbon compound deserves attention as it must involve a mechanism quite distinct from the haloperoxidase-mediated halide ion incorporation previously regarded as the major route to organohalogen compounds in nature[13]. The biotechnological potential of this novel system warrants investigation; indeed, a role for the fungal gene involved can be envisaged in the development of halotolerant crop plants, although environmental considerations may limit such an application.

I thank J. T. Kennedy for technical assistance and J. A. Buswell, P. Robinson and D. A. Seaby for helpful discussions.

Use of numbers by a chimpanzee

Tetsuro Matsuzawa

Department of Psychology, Primate Research Institute, Kyoto University, Inuyama, Aichi 484, Japan

Recent studies have examined linguistic abilities in apes[1–6]. However, although human mathematical abilities seem to be derived from the same foundation as those in language, we have little evidence for mathematical abilities in apes (but for exceptions see refs 7–10). In the present study, a 5-yr-old female chimpanzee (*Pan troglodytes*), 'Ai', was trained to use Arabic numerals to name the number of items in a display. Ai mastered numerical naming from one to six and was able to name the number, colour and object of 300 types of samples. Although no particular sequence of describing samples was required, the chimpanzee favoured two sequences (colour/object/number and object/colour/number). The present study demonstrates that the chimpanzee was able to describe the three attributes of the sample items and spontaneously organized the 'word order'.

Before the present study[11,12,14], Ai had been trained to name 14 objects and 11 colours by choosing among the set of symbols shown in Fig. 1. For the first experiment, five objects and five colours were selected from Ai's 'vocabulary' to form groups of sample items to be identified. The experimenter presented the sample items (for example, three red pencils) in the display

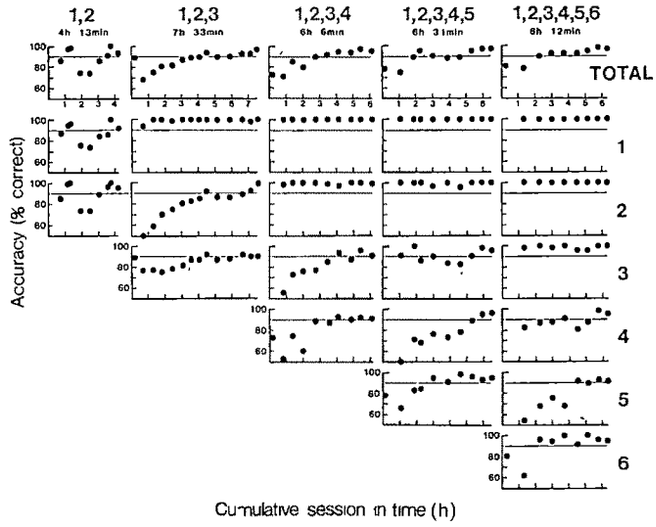

Fig. 2 Acquisition of number names for the training item, red pencils. The top row represents overall accuracy, the other rows accuracy for individual numbers. Each dot shows the performance in each session, with percentage correct plotted against the time elapsed since the beginning of training on each number set. In the first session of each stage, except for training on the number names 1 and 2, the chimpanzee received intensive training limited to the newly introduced number.

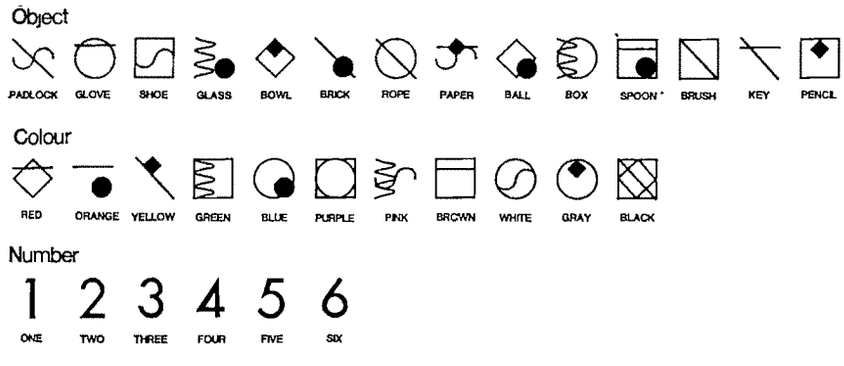

Fig. 1 Symbols used in these studies In the symbolic matching-to-sample task, the chimpanzee was trained to identify the sample item that appeared in the display window (24 × 17 × 24 cm) by pressing an illuminated key (2 × 2.5 cm) showing the assigned symbol These symbols could appear in various positions in a 5 × 6 key matrix on a console located below the display window This console was interfaced with a PDP11/V03 minicomputer. The set of operative-illuminated keys was changed from trial to trial and the positions of the keys were also changed from session to session so that the symbol, rather than the position of the correct key, had to be learned The trial ended when the chimpanzee pressed a blank key to the right of the matrix on the console In numerical naming, two methods of displaying the sample items were used to minimize the possibility that the chimpanzee would associate each numeral with a particular display pattern On some trials the samples were laid out in a row The position and the spatial density of items were changed within the area of the window in each trial so that area covered was not correlated with number of items. On other trials the items were held in one hand in front of the display window The orientation and the angular separation of items was varied from trial to trial Depending on type of object, either or both methods were used. In the first experiment, five objects (pencil, paper, brick, spoon and tooth-brush) of five colours (red, green, blue, yellow and black) were used to form groups of items to be identified

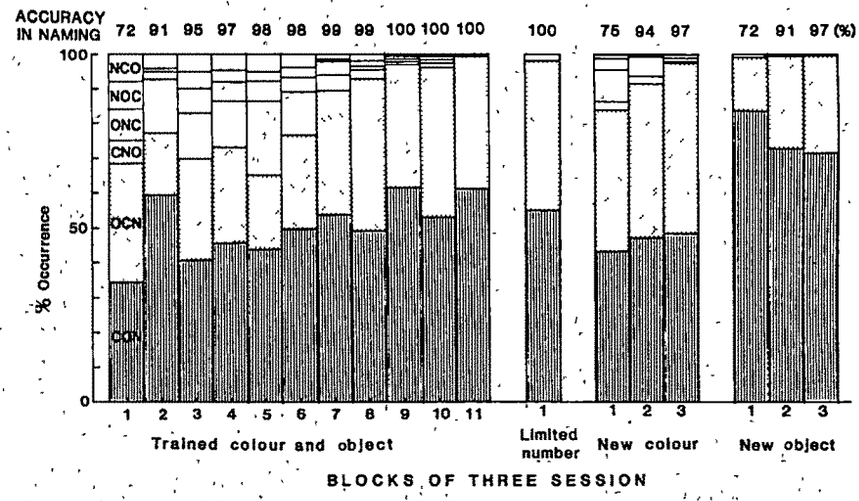

Fig. 3 Percentage of six possible sequences in three-term naming. N, number; C, colour; O, object. For example, NCO refers to trials in which the sequence 'number/colour/object' was used correctly. The open bars show the percentage of trials on which number was the first or second attribute named. The percentage of trials on which all three attributes of the sample items were named correctly is shown at the top of each column. The left panel shows the change of use of the six possible sequences as a function of three-term-naming training. A session ended when 100 rewards had been delivered. Each reward required two consecutive correct responses. Each block consists of three consecutive sessions. In the final block of three sessions of the task, the chimpanzee received 604 problems during 127 min and made only three mistakes. To investigate the determinant of the particular sequences, three kinds of tests were done. In the first test ('limited number'), the number of sample items was not varied but restricted to one of the five alternatives within a session. The objects and colours used in this first test were the same as those used in previous training. In the second test ('new colour'), new colours were introduced. The sample items consisted of the numbers from one to five, the five trained objects and five new colours, pink, brown, purple, white and grey. In the third test ('new object'), new objects were introduced. The sample items consisted of the five trained colours and five new objects, padlock, glove, glass, ball and key. In this test, the number of items to be named was restricted to one and two. Although those new samples had never been used in three-term naming, or even in simple numerical naming, the chimpanzee correctly described the three attributes of the samples. Decreasing the difficulty of numerical naming by using the same number of items in all samples in a given session, or increasing the difficulty of object or colour naming by introducing new colours and objects, had little effect on the favoured sequences. The chimpanzee seemed to have established the order of describing the three attributes of the sample items. However, the introduction of new samples had a temporary impact on the ratio of these two sequences. The introduction of new colours increased one sequence, object/colour/number. The introduction of new objects increased the use of the other sequence, colour/object/number. As those new samples were presented repeatedly, the ratio of the two favoured sequences gradually returned to the original level.

window and then pressed a start switch to light a set of numeric keys on a console. Correct and incorrect key choices were followed by different sounds. A piece of apple or a raisin was delivered after a number of consecutive correct responses. A session ended when 100 such rewards had been delivered or when 60 min had elapsed, whichever came first. Ai received one or two sessions a day. On the average, 303 trials were given in a 43-min session, with trials spaced ~8.5 s apart.

At the beginning of the first stage of training, only two numbered keys were available and only one or two red pencils were shown. The number of red pencils and corresponding number keys was increased successively. Training was continued on each number set until accuracy exceeded 90% in at least two consecutive sessions. Acquisition of number naming with red pencils only as exemplars is shown in Fig. 2. The introduction of a new number was always accompanied by poorer identification of the maximum number learned in the previous stage. For example, in the course of initial training to name six items in addition to 1, 2, 3, 4 and 5, Ai made 274 errors out of 3,004 trials, 63.1% of these confusion between 5 and 6. Moreover,

Table 1 Generalization of numerical naming to a new colour, a new object or both a new colour and object in a chimpanzee

Numbers	Accuracy on probe trials: Samples — New colour, trained object	Trained colour, new object	New colour, new object	Accuracy by chance	Accuracy of trained samples on probe trials
1, 2	0.83 (5/6) Blue Pencil	0.50 (3/6) Red Paper	0.50 (3/6) Blue Paper	0.50	0.97
1, 2, 3	0.60 (18/30)* Yellow Pencil/paper	0.33 (10/30) Red/blue Brick	0.33 (5/15) Yellow Brick	0.33	0.99
1, 2, 3, 4	0.71 (34/48)‡ Black Pencil/paper/brick	0.54 (26/48)† Red/blue/yellow Spoon	0.56 (9/16)* Black Spoon	0.25	0.99
1, 2, 3, 4, 5	0.79 (79/100)‡ Green Pencil/paper/brick/spoon	0.57 (57/100)‡ Red/blue/yellow/black Tooth-brush	0.56 (14/25)* Green Tooth-brush	0.20	0.98

The generalization was tested by inserting probe trials in which the new colour, new object or both, was used to illustrate the number. These probe trials were included among trials during which trained samples were used. On trials with trained samples, the chimpanzee was informed whether her choice was correct or incorrect. On probe trials, which were inserted once every 10 trials on the average, the choice response was followed by neither the 'correct' nor 'error' feedback sound. Proportion correct is shown for the trained items as well as for the new colour and/or object introduced in each stage of training. The numbers in parentheses show the number of trials on which the proportions are based. The last column shows the proportion correct on the trials for the trained sample items, including all the colours and objects previously used. Generalization of the number name to new objects of familiar colour, to new colours of familiar objects, and to new objects in a new colour was at first poor. Less generalization was observed with new objects than new colours in each stage of training. As additional numbers were introduced and new objects and colours were used as exemplars, the correct number names were applied not only to new colours but also to new objects.

* $P<0.05$, † $P<0.01$; ‡ $P<0.001$ significantly above the chance level (χ^2 test).

most errors (94.9%) were confusions between neighbouring numbers.

Following acquisition of a new number name, generalization to a new object and/or a new colour was tested. The specific objects and colours used as well as test performance are summarized in Table 1 and reported in more detail elsewhere[13].

Accuracy during the final two sessions of naming 1, 2, 3, 4 and 5 with all five colours and five objects exceeded 98.5% in 830 trials. To reach this level of performance, a total of 95 sessions were required. In other words, 68 h 21 min (28,799 trials) elapsed from the beginning of training. It took an additional nine sessions (6 h 12 min, 3,004 trials) for Ai to reach criterion in selecting the correct Arabic numeral for groups of up to six red pencils.

How could Ai's newly acquired numerical skills be combined with object/colour naming? To answer this question, the chimpanzee was required to name not only the number of items, but also the colour and objects used to illustrate the number.

Fifteen keys, each of which represented one of five numbers (1, 2, 3, 4, 5), five colours (red, blue, yellow, green, black) and five objects (pencil, paper, brick, spoon, tooth-brush), were operative at one time. The sequence in which the keys were depressed was free, but the chimpanzee was required to select the three keys correctly describing each of the three attributes of $5 \times 5 \times 5 = 125$ types of sample items. For example, when five blue tooth-brushes were shown in the display window as a sample item, it was necessary for Ai to press keys of '5', 'blue' and 'tooth-brush' in any order. When the chimpanzee pressed an incorrect key, the 'error' sound followed and the trial ended. The pressed key was darkened and inoperative, so that the repeated response such as 'red/red' was inhibited.

Although no particular 'word order' was required, the chimpanzee favoured two particular sequences among the six possible alternatives, colour/object/number and object/colour/number (left panel of Fig. 3). In both sequences, numerical naming was always last. In the final sessions, it generally took less than 3 s for Ai to describe the object, colour and number of the sample items. She seldom looked back at the display between each component response. The response latency in the first component was the longest and the third component (numerical naming in almost all cases) was longer than the second one. The previously favoured sequences continued to be used for new samples with new colours and/or new objects (details in the right panel of Fig. 3).

These results suggest that the readiness with which the attributes are named is a partial determinant of the favoured sequences. Accuracy in numerical naming was always lower than that in object or colour naming in the three-term naming task. Moreover, number names were learned more slowly than were the names of objects and colours. It took 1,052 trials (171 min) for Ai to reach criterion in her first object discrimination task ('padlock' and 'glove'), 538 trials (105 min) for the first colour discrimination ('red' and 'green') and 1,821 trials (253 min) for the first number discrimination ('1' and '2'). In the previous stage of two-term naming, Ai had experienced both sequences, object/colour and colour/object. The previous experience may be the factor facilitating the reversible bonding of object and colour names in three-term naming. It seems that the favoured sequences in three-term naming are determined by complex factors, which include readiness with which the attributes are named and her previous experiences.

The range of numbers (1-6), the variety of sample items (at least 125 types), generalization to new items and the complex sequence of responses make it highly unlikely that the naming depends on the mere association of particular sample items and alternative keys. The present study suggests that the chimpanzee was able to match the sample items on the basis of numerosity in addition to colour and types of object.

I thank Drs Kiyoko Murofushi and Toshio Asano for helpful discussions and support; Drs Pamela Asquith and Sheila Chase for suggesting improvements to the original manuscript. Co-localization of corticotropin releasing factor and vasopressin mRNA in neurones after adrenalectomy

Betty Wolfson, Robert W. Manning, Leonard G. Davis, Rene Arentzen & Frank Baldino Jr*

Central Research & Development Department, Experimental Station, E. I. du Pont de Nemours & Co., Wilmington, Delaware 19898, USA

The discrete anatomical distribution of arginine vasopressin and corticotropin releasing factor (CRF) immunoreactivity in the paraventricular nucleus (PVN) of the rat hypothalamus is altered after adrenalectomy[1-3]. Not only is the immunostaining of both peptides enhanced, but vasopressin immunoreactivity, normally confined to the magnocellular subdivision, becomes clear in a large percentage of CRF neurones in the parvocellular subdivision[2]. These changes in immunoreactivity may reflect changes in post-translational events, peptide metabolism or genomic activity that lead indirectly or directly to the enhanced expression of vasopressin. Here we report that levels of transcripts homologous to vasopressin messenger RNA increase in the PVN after adrenalectomy, in parallel with increases in vasopressin immunoreactivity. In fact, after adrenalectomy, vasopressin mRNA can be detected in CRF-immunoreactive neurones. These results indicate that a considerable degree of plasticity is retained by the adult neuronal genome of the rat and that this plasticity may be modulated by the endocrine environment.

CRF and vasopressin act synergistically to release adrenocorticotropic hormone (ACTH) from the anterior pituitary[4]. Recently, immunohistochemical studies have demonstrated that CRF-containing fibres in the median eminence arise from cells in the parvocellular subdivision of the PVN[5], whereas the greatest density of vasopressin-containing neurones is found in the magnocellular subdivision of the PVN[6]. After adrenalectomy, the anatomical distribution of these peptides becomes less discrete; vasopressin and CRF can be found co-localized in >70% of parvocellular neurones[2]. It has been suggested that the removal of adrenal steroids accounts for these changes in neuropeptide expression[7]. Because steroids regulate peptide synthesis by modulating genomic activity[8], it seemed possible that adrenal hormones regulate neuronal synthesis of vasopressin by influencing some process preceding mRNA translation. Therefore, we examined the effects of adrenalectomy on vasopressin mRNA levels in the PVN by applying *in situ* hybridization techniques in conjunction with standard

* To whom correspondence should be addressed.

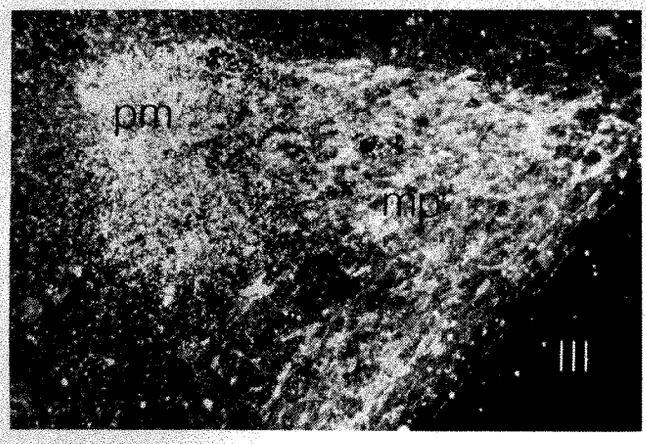

Fig. 1 Simultaneous detection of vasopressin mRNA and CRF-like immunoreactivity in the PVN of a control rat photographed under dark-field illumination. CRF-like immunoreactive neurones are confined to the medial parvocellular division (mp), whereas vasopressin mRNA (silver grains) is largely confined to the posterior magnocellular division (pm). III, Third ventricle. Scale bar, 200 μm.
Methods. Colchicine-treated (75 μg) rats were perfused with phosphate buffered saline (*p*H 7.0) followed by buffered 10% formalin containing 15% sucrose. Transverse 35-μm sections containing the PVN were cut on a freezing microtome and processed for CRF immunoreactivity using the avidin-biotin method[9] and diaminobenzidine as the chromogen. Immunostained sections were then delipidated in ethanol, rehydrated, rinsed in diethylpyrocarbonate (1 μl 5 ml^{-1}), slide-mounted and incubated overnight at room temperature with ^{32}P-labelled probe (5×10^4 c.p.m. per section) diluted in hybridization buffer (2 × SSC, 10 × Denhardt's, 50% formamide, 0.1% SDS and 0.1% denatured salmon sperm DNA). The next day, slides were rinsed in 2 × SSC for 4 h with solution changes every 15 min. Slides were then air dried and dipped in Ilford L4 nuclear research emulsion diluted 1:1 with water. Because this emulsion is fine grained, slides were exposed for 4 weeks in light-proof boxes at 4 °C. Development was performed with Kodak D-19 (diluted 1:1) for 5 min at 20 °C and followed by fixation in 30% sodium thiosulphate.

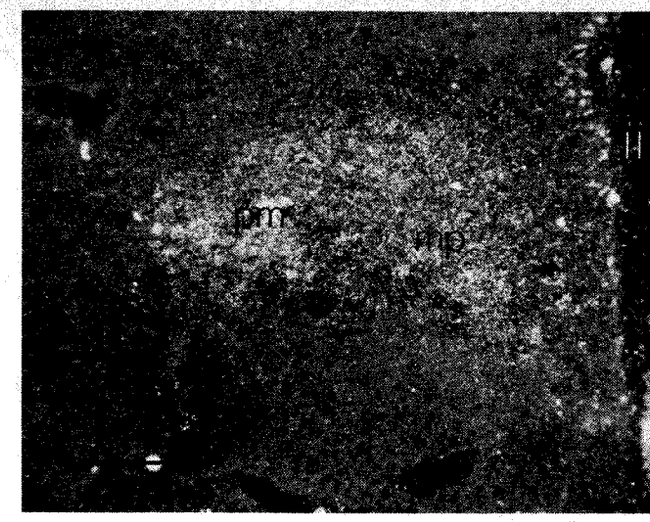

Fig. 2 Localization of vasopressin mRNA in the parvocellular PVN of an adrenalectomized rat photographed under dark-field illumination. The highest density of grains is still seen in the posterior magnocellular division (pm), but there is also a considerable amount of hybridized probe in the medial parvocellular division (mp). III, Third ventricle. Scale bar, 230 μm.
Methods. A 48-base oligonucleotide complementary to the glycoprotein region of vasopressin mRNA was prepared according to previously published methods[10]. Two different 24-mers were synthesized on an Applied Biosystems (Model 380A) DNA synthesizer and purified by reverse-phase HPLC on a μBondapak C18 column (Waters Associates). One of the 24-mers was labelled at its 5′ end with ^{32}P by reaction with [γ-^{32}P]ATP and T4 polynucleotide kinase. The 3′ end of this 24-mer was then ligated to the 5′ end of the second 24-mer, phosphorylated with ATP and T4 polynucleotide kinase, with the aid of a 17-mer holding fragment and T4 DNA ligase. The resulting 48-mer was separated from excess reactants and the complementary holding fragment by polyacrylamide gel electrophoresis in denaturing conditions. The final activity of the probe was ~10^8 c.p.m. μg^{-1}.

immunocytochemical methods. (For simplicity, the terms vasopressin mRNA and CRF- or vasopressin-immunoreactivity used here imply their putative nature.)

Adrenalectomized (5 days) and sham-operated control male Sprague–Dawley rats were colchicine-treated, perfused 48 h later and processed for vasopressin or CRF immunostaining on alternate sections, using the avidin–biotin method[9] with commercially produced antisera (Immunonuclear). *In situ* hybridization techniques with radiolabelled, synthetic oligodeoxyribonucleotide probes were then applied to detect vasopressin mRNA in the immunostained sections. The hybridization procedures used and controls for the specificity of the resultant signal were, with minor modifications, as described previously[10]. Conventional autoradiographic procedures were used to visualize hybridized probe. No differences in the hybridization signal were observed between colchicine- and non-colchicine-treated animals.

In sections from control animals, vasopressin immunoreactivity and the hybridization signal were largely confined to the magnocellular subdivision of the PVN, as expected if the probe specifically hybridized to transcripts homologous to vasopressin mRNA (Fig. 1). This localization of vasopressin mRNA was seen in all control tissue, regardless of whether vasopressin or CRF was immunostained in the section. Since vasopressin and CRF are normally distributed discretely in the PVN, the consistency of the distribution of the hybridization signal indicates that the immunoreaction product did not lead to the production of false-positive chemographic images.

Adrenalectomy induced the appearance of vasopressin immunoreactivity in dorsal and medial regions of the parvocellular PVN. Hybridized probe could also be detected in these same parvocellular regions (Fig. 2). Indeed, vasopressin mRNA could be seen in the cytoplasm of parvocellular CRF-immunoreactive neurones (Fig. 3). Adrenalectomy did not lead to the appearance of vasopressin mRNA in CRF neurones in all regions of the central nervous system (CNS) (data not shown).

These results demonstrate the ability of the endocrine environment to regulate transcript levels in a discrete region of the adult CNS. Certainly, the changes in genomic expression described here need not have been a direct consequence of decreased circulating adrenal hormones. The loss of feedback inhibition of both pituitary corticotrophs[11] and CRF-secreting neurones[5] upon adrenalectomy leaves open the possibility that elevated concentrations of ACTH or CRF contribute to the enhanced production of vasopressin mRNA. CRF has been shown to contribute significantly to the elevation of proopiomelanocortin mRNA levels seen in the pars intermedia of adrenalectomized rats[12]. Furthermore, changes in neuronal activity that might occur in response to endocrine manipulations[13,14] could themselves lead to changes in neuropeptide expression. For example, chemical depletion of adrenergic terminals in the hypothalamus leads to enhanced CRF immunoreactivity in the PVN[15]; depolarization of sympathetic ganglia is known to result in changes in their neuropeptide content[16]. Whether such indirect actions consequent to adrenalectomy also affect the observed redistribution of vasopressin mRNA remains to be determined. In contrast to the increase in vasopressin immunoreactivity reported here in the PVN after adrenalectomy, a dramatic decrease in vasopressin immunoreactivity in the adult rat habenula has been found after gonadectomy[17]. Whether this effect of gonadectomy reflects changes in genomic activity

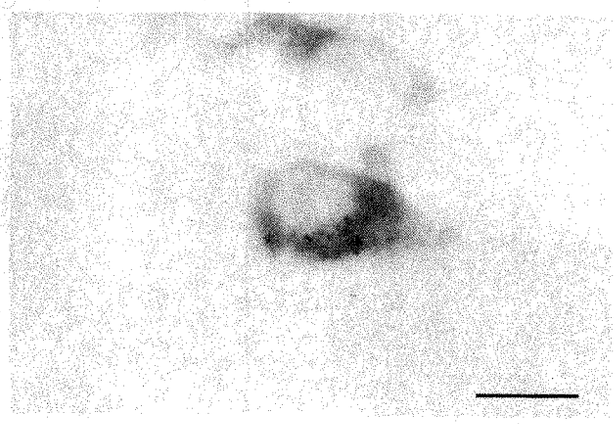

Fig. 3 CRF-immunoreactive neurone containing vasopressin mRNA. Note the confinement of the silver grains to the cytoplasm. Scale bar, 20 μm.

remains to be demonstrated. In any case, the observation that regional levels of the same neuropeptide may be differentially regulated by different humoral factors is particularly striking.

Our results show that changes in the endocrine composition caused by adrenalectomy promote the expression of vasopressin mRNA in parvocellular regions of the rat PVN. Of particular note is the induction of vasopressin mRNA in CRF-immunoreactive neurones under these conditions. These results demonstrate that differential regulation of gene expression occurs in the adult CNS in response to physiological stimuli.

We thank T. O'Kane for technical assistance, Dr S. A. Tomiko for critical comments and Y. J. King for typing the manuscript.

Stimulation of connective tissue cell growth by substance P and substance K

Jan Nilsson*, Anne M. von Euler† & Carl-Johan Dalsgaard‡

Departments of * Histology and ‡ Anatomy, Karolinska Institutet, and † Wenner-Gren Institute, University of Stockholm, Stockholm, Sweden

Connective tissue cells proliferate actively when cultured in the presence of serum. Platelet-derived growth factor (PDGF), a basic protein of relative molecular mass ~30,000, has been identified as the major serum mitogen for these cells[1]; its main physiological/pathophysiological role may be to initiate wound healing in connection with tissue injury. However, growth of cultured cells is also influenced by several other factors, including epidermal growth factor[2], fibroblast growth factor[3], insulin and somatomedins[4]. Furthermore, Rozengurt and Sinnett-Smith recently showed that bombesin, a neuroendocrine peptide isolated from frog skin, stimulates DNA synthesis and cell division in cultures of a specific subtype of 3T3 cells[5]. Substance P and substance K (also known as neurokinin A or neuromedin L) are mammalian peptides belonging to the tachykinin family[6]. Substance P has been studied extensively; it is distributed widely throughout the central and peripheral nervous system[7], including primary sensory neurones[8-10], and can be released in the periphery from axon collaterals of stimulated pain fibres[11,12] and contribute to the inflammatory response[13]. Substance K is a member of the tachykinin family isolated from mammalian spinal cord[14,15]; Nawa *et al.*[16] determined the primary structure of two types of substance P precursors, one of which contained a sequence homologous to substance K, as well as the sequence of substance P. We report here that substance P and substance K stimulate DNA synthesis in cultured arterial smooth muscle cells and human skin fibroblasts, and that this stimulation is inhibited by the substance P-antagonist spantide[17].

Smooth muscle cells were isolated enzymatically from the aortic media of adult Sprague-Dawley rats[18] and fibroblasts were isolated by outgrowth from human skin explants[19]. Secondary cultures of muscle cells and cultures of fibroblasts in the 10th to 12th passage were growth-arrested by transfer to serum-free medium for 24 h. The rate of entrance of the cells into S phase of the cell cycle was determined by counting the number of autoradiographically labelled nuclei after a 24-h incubation with ^{3}H-thymidine. Exposure to medium containing 10% newborn calf serum initiated DNA synthesis in 71.8 ± 3.8% (±s.d.) of the muscle cells and in 47 ± 5.3% of the fibroblasts, compared with 18.6 ± 3.0% and 17.1 ± 2.7%, respectively, in unstimulated cultures.

Addition of substance P or substance K to serum-free medium stimulated DNA synthesis in cultured muscle cells in a dose-dependent manner, whereas addition of bombesin had no effect (Figs 1*a*, 2). Substance K was a more potent stimulator than substance P, at 10^{-6} M producing 62.0 ± 1.4% labelled nuclei while 10^{-5} M substance P produced 38.3 ± 4.4% labelled nuclei. PDGF at 25 ng ml^{-1} produced maximal stimulation of DNA synthesis in muscle cells grown in serum-free medium (42.6 ± 4.7% labelled nuclei; see ref. 18), whereas 2 ng ml^{-1} PDGF produced only a small increase (Fig. 1*a*). DNA synthesis in muscle cells stimulated with 2 ng ml^{-1} PDGF could be further stimulated by the addition of substance P or K. However, the combined effect of substance P or K and suboptimal concentrations of PDGF was less than the sum of their individual effects. Furthermore, at concentrations $>10^{-8}$ M, substance K was more active alone than in combination with suboptimal concentrations of PDGF (Fig. 1*a*).

Substance P and substance K also stimulated initiation of DNA synthesis in fibroblast cultures; no effect was observed after treatment with bombesin (Fig. 1*b*). Again, substance K was more potent than substance P. The rate of DNA synthesis in fibroblasts stimulated with suboptimal concentrations of PDGF was further enhanced after treatment with substance P or substance K, but the enhancement was lower than the individual effects of either substance (Fig. 1*b*).

To determine the specificity of the stimulating action of substance P and substance K, we performed control experiments with cultures preincubated with spantide ([D-Arg^1, D-Trp^{7,9}, Leu^{11}]-substance P; Bachem), a substance P antagonist[17]. We found that the addition of spantide (3×10^{-6} M–3×10^{-5} M) to serum-free medium caused a limited stimulation of DNA synthesis, 3×10^{-5} M producing 26.4 ± 2.0% labelled nuclei, and a significant reduction of DNA synthesis induced by 10^{-7} M of substance P or substance K in both muscle cells and human fibroblasts. Spantide did not reduce the rate of DNA synthesis in cultures stimulated with 25 ng ml^{-1} PDGF (Table 1).

There is accumulating evidence that many factors are involved in the regulation of cell growth. The present results demonstrate

Table 1 Effect of the substance P analogue spantide on DNA synthesis induced by substance P (SP), substance K (SK) and PDGF

Medium MCDB 104 (Gibco) was used as control. The fraction of labelled nuclei was determined as described in Fig. 1 legend. Each value represents the mean of triplicate cultures.

* The first value in each group, significantly different ($P < 0.05$) from the control.

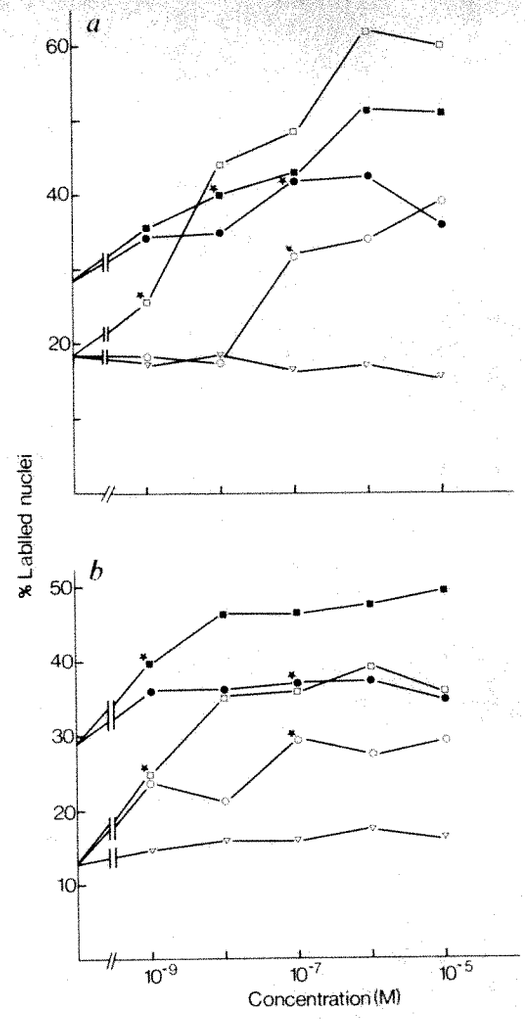

Fig. 1 Effects of substance P and substance K on initiation of DNA synthesis in smooth muscle cells (*a*) and skin fibroblasts (*b*). Subconfluent, secondary cultures of muscle cells were growth-arrested by transfer to medium MCDB 104/0.1% bovine serum albumin (serum-free medium) for 24 h. They were then incubated with 2.5 μCi ml^{-1} of ^{3}H-thymidine and various concentrations of substance P (Bachem) alone (○) or with (●) 2 ng ml^{-1} of PDGF[25] added, various concentrations of substance K (Peninsula) alone (□) or with (■) 2 ng ml^{-1} of PDGF or with various concentrations of bombesin (Peninsula) alone (▽) added for another 24 h. The cells were fixed in 3% buffered glutaraldehyde and processed for autoradiography as described elsewhere[18]. The fraction of labelled nuclei was determined by counting 500 randomly selected cells in each specimen. Values are given as means of triplicate cultures (s.d. < 20%). * Indicates the first value in each group, which is significantly different ($P < 0.05$) from the control.

that substance P and substance K, two structurally related neurotransmitters found in both the central and peripheral nervous system, may act as mitogens for connective tissue cells. The addition of 10^{-7} M of substance P alone or together with suboptimal concentrations of PDGF stimulated initiation of DNA synthesis, whereas substance K stimulated entrance to S phase at concentations as low as 10^{-9} M. Note that substance K was 100 times more potent in stimulating DNA synthesis than substance P, indicating an action via a substance P-E receptor subtype[20,21]. Substances P and K were less effective in stimulating DNA synthesis if the cells were simultaneously stimulated with suboptimal concentrations of PDGF. This lack of potentiating effect may result from the existence of similarities in the mechanisms of action of neuropeptides and growth factors. Indeed, our results indicate that PDGF decreases the stimulatory effect of substance K in smooth muscle cells, which suggests a complex interaction between the mitogenic effect of PDGF and substance K. DNA synthesis induced by substance P or substance K was markedly reduced by incubation with spantide, an analogue of substance P with antagonistic activity, suggesting a competitive inhibition of receptor binding. Spantide alone had a small stimulatory effect, consistent with the previously reported agonistic activity of the substance P analogues[7]. It is interesting that bombesin, which has two C-terminal amino acids in common with substance P and substance K, failed to induce DNA synthesis. We therefore conclude that the stimulatory effect is mediated via specific tachykinin receptors.

The mechanisms by which substance P and substance K stimulate DNA synthesis remain to be determined. However, it is interesting that both substance P[22] and PDGF[23] have been found to stimulate hydrolysis of phosphatidylinositol 4,5-bisphosphate into diacylglycerol and inositol trisphosphate and that inositol trisphosphate has recently been shown to function as a second messenger for mobilization of intracellular calcium[24], which is believed to participate in regulation of cell proliferation.

The present data suggest a possible role for tachykinins in wound healing. It is tempting to speculate that substance P and/or substance K released from peripheral neurones in connection with tissue injury not only contribute to the inflammatory response but also could help other mitogens, such as PDGF, to stimulate proliferation of surrounding connective tissue cells and thus initiate a healing response.

Fibroblasts were kindly supplied by Dr Ove Ceder and Dr Hans Kollberg; PDGF was a gift from Dr Carl-Henrik Heldin. This work was supported by the Swedish MRC (06537 and

Voltage dependence of Na/K pump current in isolated heart cells

David C. Gadsby*, Junko Kimura & Akinori Noma

National Institute for Physiological Sciences, Okazaki, 444 Japan
*Laboratory of Cardiac Physiology,
The Rockefeller University, New York, New York 10021, USA

The Na/K pump usually pumps more Na^+ out of the cell than K^+ in, and so generates an outward component of membrane current[1,2] which, in the heart, can be an important modulator of the frequency and shape of the cardiac impulse[3-5]. Because it is electrogenic, Na/K pump activity ought to be sensitive to membrane potential, and it should decline with hyperpolarization[6-9]. However, such voltage dependence of outward pump current has yet to be demonstrated[6-10], one reason being the technical difficulty of accurately measuring pump current over a sufficiently wide voltage range. The whole-cell patch-clamp technique[11] allows effective control of both intracellular and extracellular solutions as well as membrane voltage. Applying this technique to myocardial cells isolated from guinea pig ventricle, we have measured Na/K pump current between −140 mV and +60 mV, after minimizing passive currents flowing through Ca^{2+}, K^+ and Na^+ channels. We report here that strongly activated pump current shows marked voltage dependence; it declines steadily from a maximal level near 0 mV, becoming very small at −140 mV. Pump current–voltage relationships will provide essential information for testing models of the Na/K pump mechanism and for predicting pump-mediated changes in the electrical activity of excitable cells.

We used wide-tipped patch pipettes to modify intracellular ionic composition so as to reduce outward K^+ currents[12], by lowering the pipette K^+ concentration ($[K^+]_{pipette}$) to 10 mM (K^+ replaced by Cs^+) and by adding 20 mM tetraethylammonium (TEA). To diminish inward currents in Ca^{2+} and K^+ channels, external solutions were nominally Ca^{2+}-free and included small amounts of Cd^{2+}, Ba^{2+} and Cs^+. The resulting low membrane conductance facilitated the control of membrane potential over an extensive range and enhanced the signal-to-noise ratio for detection of Na/K pump current.

Rod-shaped, quiescent ventricular cells were obtained by collagenase digestion of guinea pig hearts, followed by enzyme-free incubation in high $[K^+]$, low $[Ca^{2+}]$ medium[13,14]. The cells were superfused at 36 °C with normal Tyrode's solution containing (in mM): 144 NaCl, 5.4 KCl, 0.3 NaH_2PO_4, 1.8 $CaCl_2$, 0.5 $MgCl_2$, 5.5 dextrose, 5 HEPES (*p*H 7.4). Giga-ohm seals were obtained using wide-tipped (4–5 μm), fire-polished pipettes filled with the same Tyrode's solution (pipette resistance ~1 MΩ), then, before rupturing the membrane patch, the pipette solution was exchanged[15] for one containing (in mM): 100 Cs-aspartate, 10 $Tris_2ATP$, 5 K_2-creatine phosphate, 1 NaH_2PO_4, 20 TEA-Cl, 5.5 $MgCl_2$, 5 EGTA, 5 HEPES (*p*H 7.4). After rupture of the patch, the holding potential was set at −40 mV to inactivate Na^+ channels and, after allowing ~5 min for the cell interior to equilibrate with the pipette solution (see Fig. 1*A*), the cells were superfused with nominally Ca^{2+}-free Tyrode's solution ($CaCl_2$ replaced by 1.8 mM $MgCl_2$, 0.9 mM $BaCl_2$, 0.2 mM $CdCl_2$ and 1 mM CsCl). In these conditions, membrane currents elicited by voltage steps were small and largely time-independent (Figs 1*B*, 2*A*), confirming that channel currents were depressed.

Figure 1*A* shows that a sudden increase in $[Na^+]_{pipette}$ from 1 mM to 34 mM (Na^+ replacing Cs^+) caused a rapid outward shift of holding current which was completely abolished by external application of 10 μM ouabain. The fact that ouabain specifically inhibits the Na/K pump suggests that, at −40 mV, the entire outward current shift caused by raising the pipette (and, hence, intracellular) $[Na^+]$ results from Na/K pump activation. To determine effects at other voltages, we applied 300-ms clamp pulses to potential levels between −140 mV and +60 mV. Figure 1*B* shows samples of the currents obtained in the presence of high pipette $[Na^+]$ immediately before (*a*) and just after (*b*) pump inhibition by ouabain; *c* shows the ouabain-sensitive components obtained by digital subtraction of the corresponding traces in *a* and *b*. These difference traces already indicate that the size of the ouabain-sensitive current varies with membrane potential.

The detailed voltage dependence of the ouabain-sensitive current is illustrated in Fig. 2. The different symbols in Fig. 2*A* show current levels measured during the four data-collection periods numbered in Fig. 1*A*. The currents in the presence of ouabain (●) are practically superimposable on those recorded with $[Na^+]_{pipette}$ of 1 mM (△), arguing that, over the entire voltage range examined, the outward current elicited by raising the intracellular $[Na^+]$ results from activation of the Na/K pump. The data points in Fig. 2*B* show the amplitudes of the difference currents, obtained by digital subtraction of the currents in Fig. 2*A*: triangles show the Na^+-activated current, and the open and solid circles show the ouabain-sensitive current determined, respectively, by washing on, and washing off, ouabain. All three sets of points demonstrate that the ouabain-

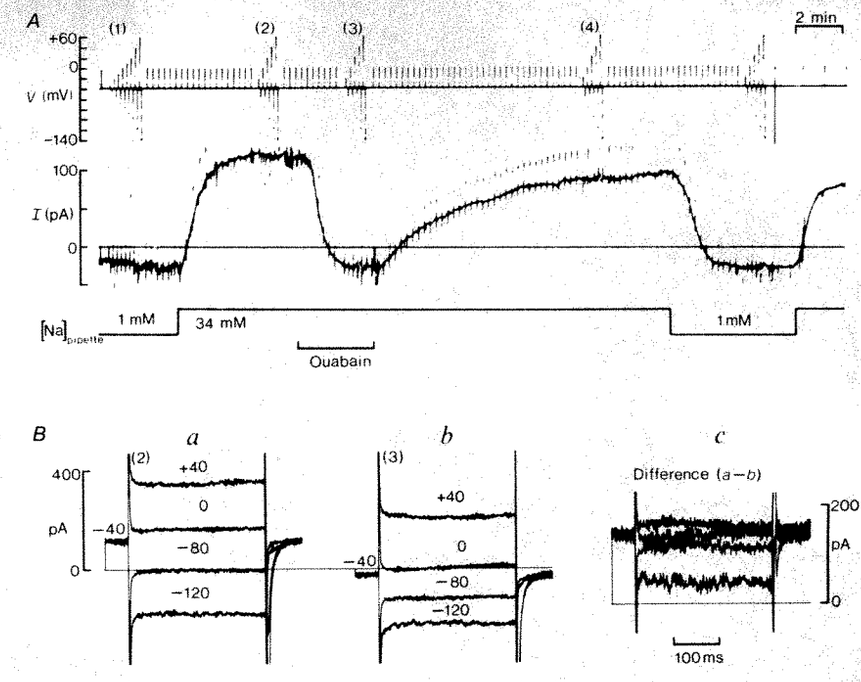

Fig. 1 Current changes due to activation or inhibition of the Na/K pump in a ventricular cell superfused with 5.4 mM K^+, Ca^{2+}-free Tyrode's solution. *A*, Chart recording: upper trace, membrane potential; middle trace, membrane current; the lower line indicates approximate timing of step changes in $[Na^+]_{pipette}$ between 1 and 34 mM, and the bar beneath it marks the exposure to 10 μM ouabain; the numbers above the voltage trace indicate acquisition of four sets of current–voltage data. To change the pipette solution[15], negative pressure (~ −30 cm H_2O) draws fluid from a miniature reservoir through fine silastic tubing and delivers it to within 200 μm of the pipette tip via a narrow, tapered polythene catheter attached to a 25-gauge stainless steel tube. A constriction device closes the silastic tube during transfer between reservoirs. To exchange the <20 μl volume between pipette tip and reservoir takes ~30–60 s. *B*, Superimposed sample current records taken from *A*, just before (2)(*a*) and during (3)(*b*) exposure to ouabain. The pulse potential is indicated for each record; holding potential −40 mV. Records were low-pass-filtered at 2 kHz and digitized at 0.4-ms intervals. *c*, Superimposed difference currents obtained by computer subtraction of each record in *b* from its counterpart in *a*; pulse potentials were, from top to bottom, 0, +40, −80 and −120 mV. Note the expanded current scale in *c*.

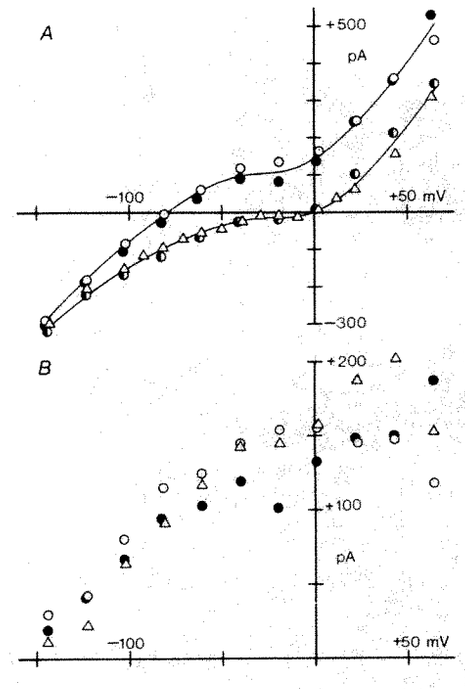

Fig. 2 Voltage dependence of current associated with Na/K pump activity. Data from the experiment in Fig. 1. *A*, Net membrane currents in the presence and absence of Na/K pump activity. Ordinate, steady current levels, obtained by averaging digitized values over the final ~100 ms of each 300-ms pulse. Abscissa, membrane potential during the pulse. The data were recorded during the periods numbered in Fig. 1*A*: △ (1), 1 mM $[Na^+]_{pipette}$; ○ (2), 34 mM $[Na^+]_{pipette}$; ◐ (3), 34 mM $[Na^+]_{pipette}$ during exposure to ouabain; ● (4), 34 mM $[Na^+]_{pipette}$ after recovery from ouabain. Arbitrary curves were fitted to the points by eye. *B*, Steady-state levels of difference currents derived by subtracting currents recorded in the absence of Na/K pump activity from those recorded, at the same voltage, in its presence. Ordinate, amplitudes measured as in *A*; abscissa, membrane potential. The three sets of points are: △ (2)−(1), current activated by raising $[Na^+]_{pipette}$; and ouabain-sensitive current on ouabain application [○, (2)−(3)] and ouabain withdrawal [●, (4)−(3)]. Because these ventricular cells have a flat, rectangular shape, the apparent cell surface was approximated as 2 × mean width × mean length. Comparison with cell capacitance measurements, however, suggests that actual membrane area is 2–3 times greater than this approximation, presumably because of T-system and sarcolemmal caveolae. The true pump current density is thus probably 2–3 times smaller than that estimated here.

sensitive current attains a maximal amplitude near 0 mV and, at negative potentials, declines roughly linearly with voltage towards an extrapolated zero-current potential near ~ −160 mV. Very similar current–voltage characteristics were obtained in a total of nine cells ($[Na^+]_{pipette}$ 34–41 mM) exposed to 5.4 mM K solution to which 10–20 μM ouabain or 50 μM strophanthidin was added to inhibit the Na/K pump; the zero-current potential estimated by linear extrapolation averaged −156 ± 14 mV (±s.d.), and the current amplitude at 0 mV was +160 ± 69 pA per cell (equivalent to 3 ± 1 μA cm^{-2} if related to apparent cell surface, but see Fig. 2 legend).

Before we can conclude that cardiotonic steroid-sensitive current is simply Na/K pump current, possible contributions from two other sources must be considered. One possibility, that cardiotonic steroids alter membrane current other than via their effect on the Na/K pump, is eliminated by the current–voltage relationships in Fig. 3*A*, which show that if the pump is first inhibited by exposure to K^+-free solution, application of 50 μM strophanthidin has no effect. A second possibility is contamination by an indirect effect of pump inhibition. Thus, despite our precautions to minimize K^+-channel currents, the cardiotonic steroid-sensitive current (and also the Na^+-activated current) may still contain a component reflecting changes in K^+ concentration in an unstirred extracellular space, caused by the

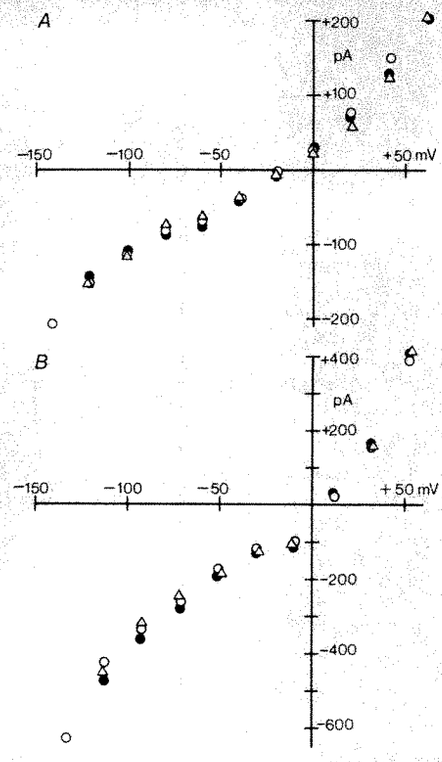

Fig. 3 Control current–voltage relationships demonstrating that, in the absence of Na/K pump activity, membrane current is unaffected either by application of strophanthidin (*A*), or by a 10-fold change in external $[K^+]$(*B*). *A*, 54 min after raising the $[Na^+]_{pipette}$ to 41 mM, the Na/K pump was inhibited by exposure to K^+-free solution, causing a 143-pA reduction in current at 0 mV. Current–voltage relationships were then determined before (○), during (△) and after (●) exposure to 50 μM strophanthidin. The points show steady current amplitudes measured as in Fig. 2. Holding potential −40 mV. *B*, 9 min after raising $[Na^+]_{pipette}$ to 34 mM, 20 μM ouabain inhibited the Na/K pump, causing a 118-pA inward shift of current at 0 mV. Current–voltage relationships were then determined in 5.4 mM K^+ (○), 1 mM K^+ (△) and 10 mM K^+ (●) external solutions, Na^+ replacing K^+ or vice versa. The points show steady currents. Holding potential −30 mV.

changes in pump activity. Figure 3*B* confirms, however, that once the pump is inhibited (in this case by 20 μM ouabain), a 10-fold change in external $[K^+]$ has virtually no effect on membrane current.

We conclude, therefore, that Fig. 2*B* illustrates faithfully the Na/K pump current–voltage relationship at high pump rates; its general shape conforms to thermodynamic expectation[6–8], as do our preliminary results indicating that a rightward shift of the pump current–voltage relationship accompanies the reduction in pump current caused by lowering either $[Na^+]_{pipette}$ or external $[K^+]$. Detailed analysis will require higher resolution current measurements to be made, probably using averaging techniques, under various ionic and metabolic conditions.

That such marked voltage dependence of outward Na/K pump current (Fig. 2*B*) has not been documented previously is probably attributable both to the limited voltage ranges explored (for example, −20 to −90 mV for cardiac preparations[4,10]), and to the difficulty of clearly distinguishing pump current from other currents. For example, pump-mediated changes in extracellular $[K^+]$ should act via inwardly rectifying K^+ channels to distort current–voltage relations of the type shown in Fig. 2*A* by making inward K^+ currents smaller at high, than at low, pump rates. This would result in more parallel current–voltage relations than those in Fig. 2*A*, so that the difference currents (see Fig. 2*B*) would show less voltage dependence. Voltage sensitivity of inward current generated by the backward-running Na/K pump in squid axons has been reported recently[16], albeit in the opposite direction to that expected on simple thermodynamic grounds.

The rapid reversal of ouabain action shown here (Fig. 1*A*; strophanthidin is still severalfold faster) contrasts with its poor reversibility in intact Purkinje fibres from sheep and dog hearts (for example, see ref. 17), but it is not yet clear whether this reflects a mere species difference or results from collagenase treatment of the cells.

Na/K pump current contributes significantly to the electrical activity of cardiac cells[4,5]; a sustained increase in heart rate, for example, leads to Na/K pump-mediated hyperpolarization and abbreviation of the cardiac action potential[3,5]. Full analysis or simulation of such effects in heart, nerve or muscle cells requires knowledge of the voltage dependence of the Na/K pump current. Accurate determination of pump current–voltage relationships under various conditions is thus vital to our understanding of both the mechanism of the Na/K pump and its role in modifying electrical activity.

NMR technique for assessing contributions of heavy and light chains to an antibody combining site

Jacob Anglister, Tom Frey & Harden M. McConnell

Stauffer Laboratory for Physical Chemistry, Stanford University, Stanford, California 94305, USA

Nuclear magnetic resonance (NMR) has been used extensively to study the structure of antibody combining sites[1,2]. In recent studies we have observed the proton resonance spectra of the Fab fragment of a monoclonal anti-spin-label antibody derived from a hybridoma grown on various specifically deuterated amino acids[3,4]. The broadening of the proton resonance signals by the paramagnetic hapten, together with selective deuteration, has allowed the identification of most of the amino acids in the combining-site region of this antibody and has also provided estimates of distances between amino-acid protons and the unpaired electron[5]. Here we show how recombination of specifically deuterated heavy and light chains permits the assignment of single amino-acid proton resonance signals to either the heavy or light chain. In addition, the spectra of such recombinants demonstrate that their combining-site structures must be almost identical to the native structure.

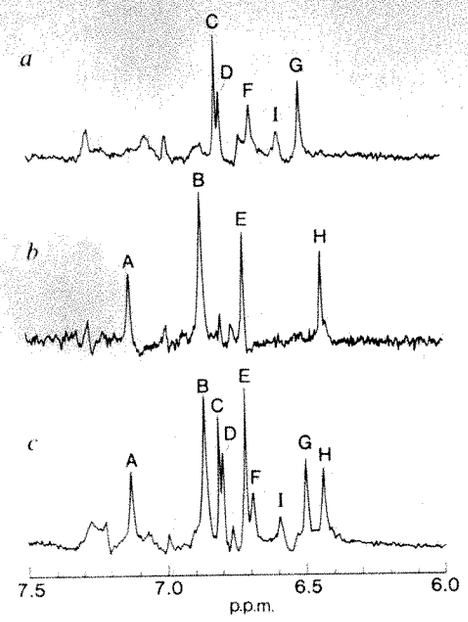

Fig. 1 NMR difference spectra for selectively deuterated Fab fragments of a monoclonal anti-spin-label antibody. *c*, Signals A–I are each due to pairs of protons in the 3,5 ring positions of tyrosine residues in the combining-site region of the ANO2 antibody. Spectra *a* and *b* give the corresponding signals from protons in the light chain and heavy chain, respectively. Note that the spectrum in *c* is, to a good approximation, the sum of the spectra in *a* and *b*. (See text for details.)

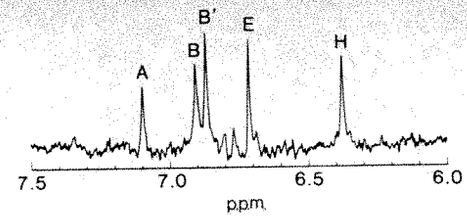

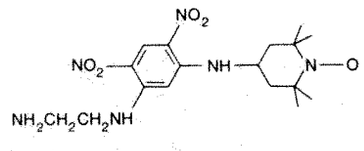

Fig. 2 NMR difference spectrum for a selectively deuterated Fab fragment of a monoclonal anti-spin-label antibody. The proton resonance signals arise from pairs of protons in the 3,5 positions of the tyrosine residues of the Fab heavy chain. These resonance signals are the same as those in Fig. 1*b*, except that in the present case the combining site is occupied by the chemically reduced non-paramagnetic form of the spin-label hapten (the hydroxylamine) whereas the signals in Fig. 1*b* arise from a combining site that is unoccupied. Note that the presence of the hapten leads to splitting of signal B in Fig. 1*b* (due to two tyrosines and four protons) into two signals (B and B') in Fig. 2.

The murine IgG_1 monoclonal anti-spin-label antibody (ANO2) was derived from a hybridoma grown on specifically deuterated amino acids, as described previously[3]. Two preparations of Fab were obtained: one (Fab I) was obtained from the hybridoma grown on perdeuterated tryptophan, perdeuterated phenylalanine and perdeuterated tyrosine; the second (Fab II) was obtained from the hybridoma grown on perdeuterated tryptophan, perdeuterated phenylalanine, and tyrosine deuterated at the 2,6 ring positions. The Fab fragments, prepared as described previously[3], were partially reduced and alkylated. The heavy (H)-chain fragment and the light (L) chain were separated on a DEAE column under denaturing conditions (8 M urea, Tris-glycine buffer, *p*H 8.2), then the heavy-chain fragments and light chains were recombined to produce the recombinants H(I)L(II) and H(II)L(I). The urea solution was made 1 M in propionic acid. The recombinants were dialysed against 1 M propionic acid and then twice against each of the following: water, 5 mM acetate buffer *p*H 5.8, 5 mM acetate buffer *p*H 5.8 containing 0.15 M NaCl, and phosphate-buffered saline *p*H 7.2 (at least 12 h for each). A similar procedure for reconstitution of a whole antibody molecule has been described previously by several groups[6,7].

Figure 1 shows the proton resonance difference spectra ΔH(II)L(II), ΔH(II)L(I) and ΔH(I)L(II), where Δ = proton resonance spectrum of Fab − proton resonance spectrum of the Fab fragment with paramagnetic spin-label hapten bound. The paramagnetic spin-label hapten has the formula

The proton resonance signals in Fig. 1*a* arise from the 3, 5 protons of tyrosines in the light chain that are in the combining-site region (within 17 Å of the unpaired spin[5]). The signals in Fig. 1*b* are due to the 3,5 protons of the tyrosines of the heavy chain in the combining-site region.

That the spectrum in Fig. 1*c* is very nearly the sum of the spectra in Fig. 1*a* and *b* represents compelling evidence that the combining-site structures are virtually the same in all three cases; this is because resonance positions, intensities and linewidths are sensitive to conformation, motional freedom and environment. A similarity in structure between native and reconstituted IgG was observed previously using circular dichroism and optical rotatory dispersion[7,8].

Our spectra show that there are five tyrosines in each chain in the combining-site region. Signal I from the light chain is weaker because it is farther from the unpaired electron. In each tyrosine signal the two proton resonance lines are equivalent due to rapid rotation of the aromatic ring. Similar conclusions are reached from the proton resonance spectra of the Fab fragment containing tyrosine deuterated in the 3,5 positions (data not shown), that is, there are five tyrosines in each chain, and the conformation of the combining site in this reconstituted Fab is very similar to the conformation in the native Fab.

Signal B in Fig. 1*b* arises from two tyrosines, as is evident from the observed intensity. Figure 2 shows that this signal is split in a difference spectrum, Δ = spectrum of Fab containing the reduced spin label (nitroxide to hydroxylamine) − resonance spectrum of Fab to which the paramagnetic spin label is bound. Interestingly, all the tyrosine proton resonance signals in Fig. 2 remain sharp, and some shift in resonance position when the non-paramagnetic hapten is in the combining site. Presumably, some of these tyrosine residues are in contact and/or are hydrogen-bonded to the hapten. Nonetheless, the motional freedom remains large enough to yield sharp resonance signals (4–7 Hz linewidth at half height).

In previous studies using double difference spectra, we demonstrated the presence of three to five threonines in the combining-site region[4]. In the present study we have used double difference spectra involving two recombinant Fab fragments to establish the presence of two threonine residues on the light chain and two to three threonine residues on the heavy chain in the combining-site region. One Fab fragment was not labelled and the other had deuterated threonine in the light chain (data not shown).

Note that the 'combining-site region' is defined as the region within 17 Å of the unpaired electron, and that proton resonance signals in this region are obtained from the difference spectra Δ = proton resonance spectrum of Fab − proton resonance spectrum of Fab with paramagnetic spin-label hapten bound. The geometry of the hapten is such that the protons of all amino acids in contact with the hapten are included in this combining-site region. The 'combining site' is thus fully included within

the 'combing-site region.' Integration of the difference spectra and assignment of the resonances to specific types of amino acids reveal that the difference spectra represent contributions from ~50 amino acids[3,4], while the entire Fab fragment contains 440 amino acids. It is probable that some, or all, of the tyrosine residues have a significant role in affecting the structure of the combining site, irrespective of whether they are in contact with the hapten or not.

The present study demonstrates that NMR, coupled with specific amino-acid deuteration and with heavy- and light-chain recombination, can be used to establish the contributions of the heavy and light-chain amino acids of an IgG monoclonal antibody to the combining-site region, provided the relevant hapten or antigen produces a suitable perturbation of nuclear resonance signals. Therefore, NMR studies offer the possibility of obtaining a working model of the combining-site structure of the ANO2 monoclonal antibody when the complete amino-acid sequence beomes available. The difference between the spectra in Fig. 1*b* and Fig. 2 indicates the information potentially available for non-paramagnetic haptens/antigens. Some of the resonances in the spectrum in Fig. 2 undergo changes in chemical shift relative to their positions in the spectrum in Fig. 1*b*. These resonances show up in a difference spectrum; Δ = spectrum with reduced spin label − spectrum without hapten, implying that useful information on combining-site structure may sometimes be obtained even with non-paramagnetic haptens.

Comparison of α-tropomyosin sequences from smooth and striated muscle

Nelson Ruiz-Opazo, Judah Weinberger* & Bernardo Nadal-Ginard†

Laboratory of Molecular and Cellular Cardiology, Department of Cardiology, Children's Hospital and Department of Pediatrics, Harvard Medical School, 300 Longwood Avenue, Boston, Massachusetts 02115, USA

Tropomyosins are a closely related family of proteins with a dimeric α-coiled-coil structure[1]. Skeletal isoforms are composed of two types of subunits, α and β[2-4] which, in turn, are assorted into two main molecular species αα and αβ[5-7]. Both isoforms are present in different molar ratios in individual skeletal muscle types[8,9]. In small mammals, however, only α-chain is expressed in cardiac muscle[8]. Tropomyosin, in association with the troponin complex (troponin-I, -T and -C) plays a central role in the Ca^{2+}-dependent regulation of vertebrate striated muscle contraction[10-12]. On the other hand, despite structural similarities with the striated isoforms, the function of this protein in smooth muscle and non-muscle cells remains unknown, because in these cells contraction is thought to be regulated by myosin-linked processes independently of tropomyosin[13-15]. Here we report the nucleotide sequences of cloned complementary DNAs for rat striated and smooth muscle α-tropomyosin. Comparison of the derived amino-acid sequences reveals the existence of tissue-specific peptides that delimit the putative troponin-I and troponin-T binding domains of tropomyosin. S_1-nuclease mapping studies reveal the existence of three distinct α-tropomyosin messenger RNA isoforms each encoding a different protein; these isoforms are tissue-specific, developmentally regulated and most probably encoded by the same gene.

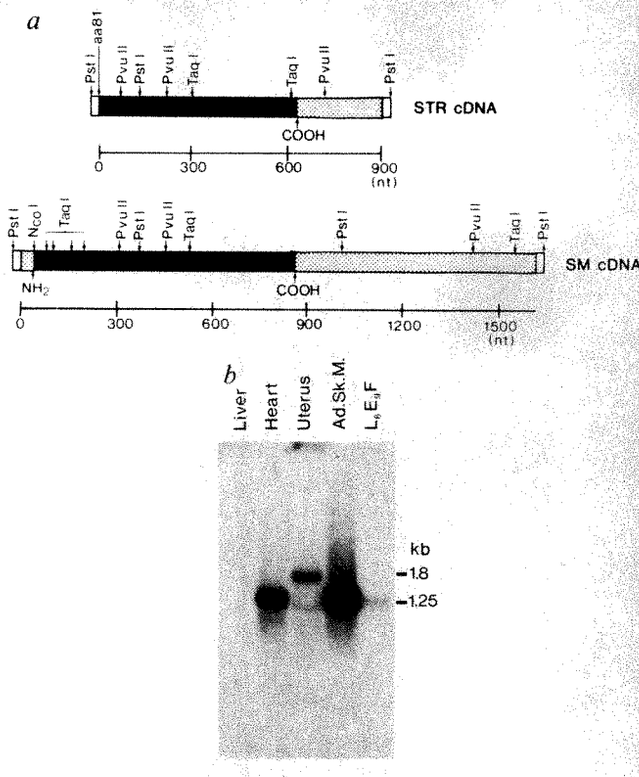

Fig. 1 Isolation and characterization of rat smooth and striated muscle α-tropomyosin cDNA clones. *a*, Partial restriction endonuclease map of striated (STR) and smooth (SM) muscle cDNA clones. Solid, stipled and open bars indicate amino-acid coding, 3′ and 5′ untranslated regions and GC tails, repsectively. The position of the first (residue 81, $-NH_2$) and last ($-COOH$) codons are indicated. The uterus-derived cDNA clone (~1.7 kb) contains mRNA sequences starting at the poly(A) track and extends all the way through the 5′ untranslated region. The striated muscle-derived cDNA clone (~0.9 kb) spans the mRNA from the poly(A) track up to codon 81. *b*, Hybridization of the smooth muscle cDNA clone to a panel of total cellular RNAs (20 μg per lane) isolated from different tissues. The ^{32}P-labelling (nick-translation) hybridization and blotting procedures were performed as described previously[40]. The size of the two hybridizing mRNA species is indicated in kb. Ad. Sk. M. and L_6E_9F represent hind leg adult skeletal muscle and L_6E_9 myotubes[16], respectively. The cloning of striated and smooth muscle cDNA was performed with mRNA–DNA hybrids annealed to pBR322 essentially as described[41,42] using RNA isolated by the hot phenol procedure[43] from adult rat hind leg and gravid uterus. One α-tropomyosin cDNA clone was isolated from each cDNA library using a previously characterized cDNA clone which cover residues 80–120 in the α-tropomyosin sequence[44].

Partial restriction maps of smooth and striated muscle α-tropomyosin cDNA clones are shown in Fig. 1*a*. The uterus-derived cDNA clone, of some 1.7 kilobases (kb), contains mRNA sequences starting at the poly(A) track and extends all the way through the 5′-untranslated region. The striated muscle-derived cDNA clone (~0.9 kb) spans the mRNA from the poly(A) track up to residue 80. To ascertain the tissue-specificity of the two cDNA clones, we performed blot analysis of RNA isolated from different tissues (Fig. 1*b*). Using the smooth muscle cDNA clone as probe, two size-classes of α-tropomyosin mRNA were detected: a 1.25-kb mRNA present in adult ventricular

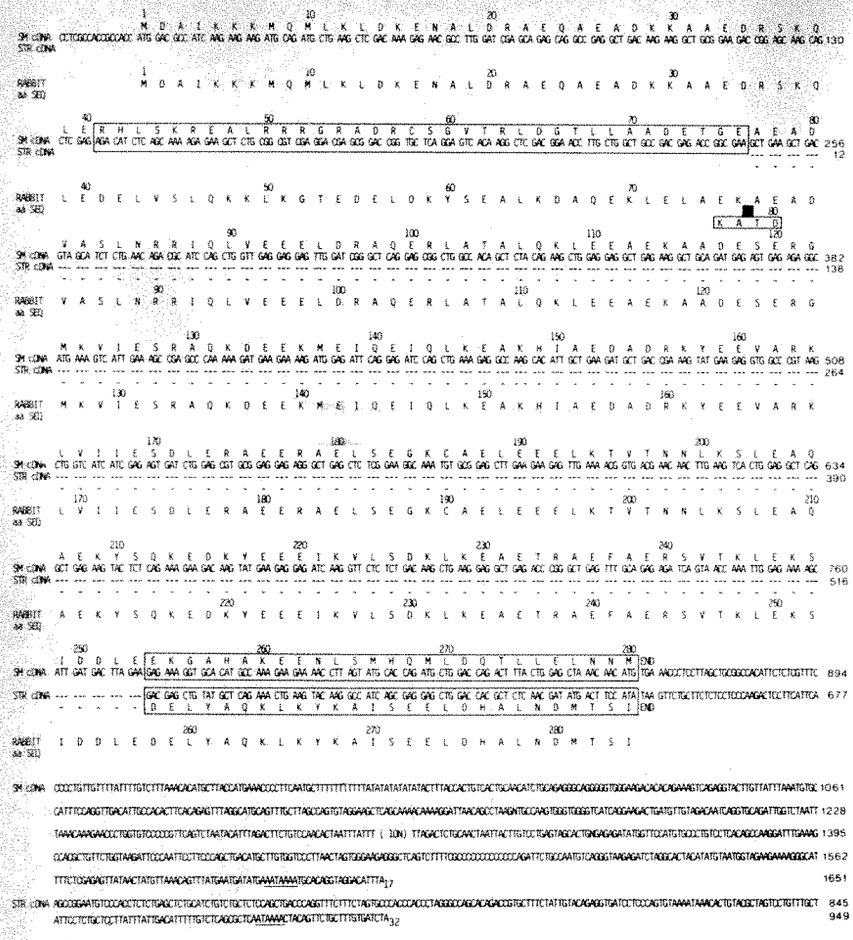

Fig. 2 Nucleotide and derived amino-acid sequence comparison of smooth and striated muscle α-tropomyosin cDNA clones. Nucleotide sequence of the smooth and striated muscle α-tropomyosin-cDNA clones were determined by cloning of gel-purified restriction fragments from both cDNA clones into M13 mp cloning vectors and subsequently sequenced according to Sanger *et al.*[45]. The deduced amino-acid sequences for the smooth and striated muscle α-tropomyosins are shown on top and underneath, respectively, of the corresponding nucleotude sequences. The AATAAA sequence of both cDNAs are underlined. Note that a second AAATAAA sequence is located 75 nucleotides upstream of the used one in the striated muscle cDNA sequence, suggesting the existence of two different poly(A) addition sites. The isotype-switch peptides sequences are boxed (residues 41–76 and 254–280 of the smooth muscle isoform). Most of the striated muscle cDNA sequence (residues 77–253, smooth muscle isoform) is shown as dotted lines indicating identity with the analogous region of the smooth muscle isoform. The rabbit α-tropomyosin residue sequence[3] has been aligned with the rat α-tropomyosin isoforms by boxing the extra four amino acids out of the linear arrangement of the sequence.

myocardium, uterus, skeletal muscle and L_6E_9 myotubes[16] (L_6E_9F) and a 1.8-kb-long mRNA expressed mainly in uterus. Uterine cells contain the highest concentration of the 1.8-kb mRNA and the lowest of the 1.25-kb species, whereas the converse is true for heart and skeletal muscle. Longer exposure of the L_6E_9F lane also shows that, although both mRNAs are present in the myotubes of this clonal cell line, the 1.25 kb species is predominant. Based on the differences in size and tissue distribution, the 1.25- and 1.8 kb mRNA species probably represent the mRNA coding for the striated and smooth muscle α-tropomyosin mRNA isoforms, respectively.

Examination of the nucleotide sequences shown in Fig. 2 reveals several new structural features of tropomyosin proteins. First, the smooth muscle α-tropomyosin is 280-residues long and 4 residues shorter than the rabbit skeletal muscle isoform[3]. Second, the rat striated muscle isoform is identical in amino-acid sequence to its rabbit counterpart, at least throughout the regions which have been compared (residues 81–284 of the rabbit molecule). Third, the comparative analysis between the smooth and striated muscle isoforms uncovers 'isotype-switch peptides' that reside in different positions along the protein molecule. The striated muscle α-tropomyosin is identical in amino-acid sequence to the smooth muscle isoform except for residues 258–284 (striated muscle sequence) that defines a carboxy-terminal 'isotype-switch peptide'. In addition, comparison of the rabbit striated muscle α-tropomyosin with the rat smooth muscle isoform shows them to be identical in sequence except for two regions: from residues 41–80 (striated muscle sequence), which depicts an amino-proximal isotype-switch peptide, and the carboxy-terminal isotype-switch peptide discussed above. By S_1 nuclease mapping, we have demonstrated that the rat striated muscle α-tropomyosin also has the amino-proximal isotype switch peptide in common with rabbit striated muscle (data not shown). Further inspection of the smooth muscle α-tropomyosin amino-acid sequence in the amino-proximal isotype-switch peptide (smooth muscle residues 41–76) reveals that the 3–4–3–4-periodicity of hydrophobic residues characteristic of the tropomyosin proteins[17,18] is interrupted significantly at positions 46 (R), 50 (R), 53 (G), 57 (R) and 60 (G) (Fig. 2). The occurrence of such residues, especially those that are charged, could lead to a local disruption of the α-helix, which has been suggested to affect the stability of the coiled-coil at the protein level[19]. These local differences in structure could alter the interaction of the smooth muscle α-tropomyosin with other components of the contractile apparatus.

Recently, it has been suggested that the binding of troponin-I to tropomyosin enhances cooperatively the binding of troponin-T to tropomyosin[20]; however, the location of the troponin-I binding site on tropomyosin has not yet been determined. The interaction of tropomyosin with troponin-T seems to occur near Cys 190 (site 2)[21–27] and at a site close to or at the carboxy-terminus (site 1) of the tropomyosin molecule[28,29]. As shown in Fig. 2, the only difference in primary sequence between the smooth and striated α-tropomyosins resides on the isotype-switch peptides. Therefore, it is likely that these two peptides specify the troponin-I (residues 41–80) and troponin-T site 1 (residues 258–284) binding domains, respectively. These isotype-specific peptides also can explain the observed differences in actin binding and in the actin activation of myosin between the two α-tropomyosin isoforms[30]. At the nucleotide level, the most striking observation from the comparative analysis between the striated and smooth muscle cDNA clones is their identity in the region coding for residues 81–257 (striated muscle sequence) (Fig. 2). In contrast, sequences located 3′ from codon 257 are unique for each cDNA. The fact that in the common amino-acid coding sequence of the two mRNAs there is not a

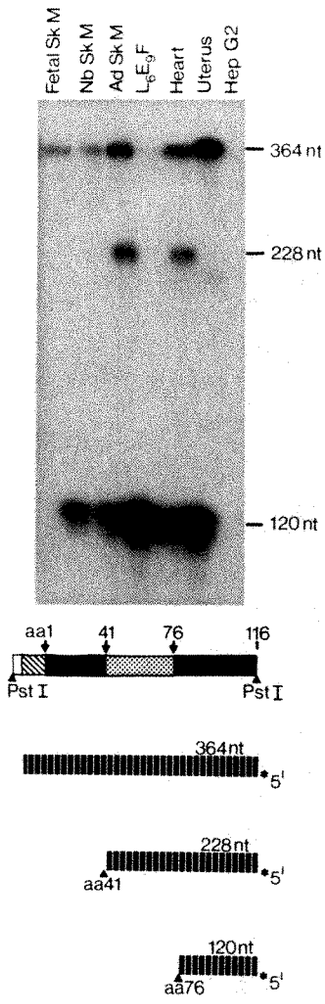

Fig. 3 Developmental and tissue-specific expression of α-tropomyosin mRNAs. The S_1 nuclease mapping studies were done under condition essentially described by Mahdavi *et al.*[46]. The 5′ end-labelled fragment was hybridized as a double-stranded probe to 30 μg total RNA under RNA-loop conditions[47,48]. After hybridization, the mixture was incubated with 600 U m^{-1} of enzyme and the S_1 nuclease-resistant products were analysed by 6% polyacrylamide/8.3 M urea gel electrophoresis[46] and their sizes estimated by comparison with 0X174 size standards. RNA samples isolated from 18-day-old fetal skeletal muscle (fetal Sk.M.), newborn skeletal muscle (Nb.Sk.M.), adult skeletal muscle (Ad.Sk.M.), adult ventricular myocardium (heart), gravid uterus (uterus), L_6E_9 myotubes (L_6E_9F) and hepatocellular carcinoma cell line ($HepG_2$) as a negative control were analysed. The 5′ end-labelled probe was generated by end-labelling of the restriction fragment with [γ-^{32}P]ATP (NEN; specific activity 3,000 Ci m-mol^{-1}) using T_4 polynucleotide kinase (Boehringer Mannheim). The 364-base pair long 5′-most *Pst*I/*Pst*I restriction fragment from the smooth muscle cDNA clone (Fig. 1*a*), labelled at the 5′ end with [γ-^{32}P], was used in the S_1 nuclease mapping studies. This probe contains the 16 nucleotides of the 5′ untranslated region of the smooth muscle cDNA down to codon 116, thus including the sequence coding for the amino-proximal isotype-switch peptide (smooth muscle sequence residues 41–76). The *Pst*I site at codon 116 lies in a region which is common to both types of cDNAs. Therefore, protection from S_1 nuclease digestion of the full-length probe (364 bases) indicated hybridization to homologous smooth muscle α-tropomyosin mRNA, whereas protection of a 120-base-long fragment represents hybridization to the striated muscle α-tropomyosin mRNA. Protection of subfragments other than 120 bases long would indicate the existence of new α-tropomyosin isoforms that diverge from the smooth muscle sequence at positions different from the striated muscle isoform.

single nucleotide substitution (even at the wobble position) strongly suggests that a single gene specifies the expression of these two tissue-specific α-tropomyosin isoforms by a complex process of alternative splicing. This possibility has been confirmed recently by the isolation of a single α-tropomyosin gene that contains all the common and isotype-specific sequences of the cDNA clones (N.R.-O. and B.N.-G., in preparation).

To study the developmental and tissue-specific expression of the α-tropomyosin mRNAs, S_1-nuclease mapping analysis of RNA isolated from different rat tissues was performed as described in Fig. 3 legend. Three distinct fragments are protected from S_1-nuclease digestion by skeletal and ventricular adult muscle RNA. Two of these fragments, 120- and 364-bases long, are consistent with the sizes predicted to be protected by striated (α_1 tropomyosin) and smooth muscle (α-tropomyosin) mRNAs, respectively. The third band, 228-bases long, demonstrates the existence of a new α-tropomyosin mRNA (striated muscle α_2 tropomyosin) that diverges from the smooth muscle cDNA probe at the region corresponding to codon 41, which is the first residue of the amino-proximal isotype-switch peptide (smooth muscle residues 41–76). Identity between the striated muscle α_2- and smooth muscle α-tropomyosin mRNAs spans the region encoding residues 41–116 and, therefore, includes the amino-proximal isotype-switch peptide (Fig. 3).

The three different α-tropomyosin mRNAs are tissue-specific and developmentally regulated. The α_1- and α_2-tropomyosin mRNAs are produced only in striated muscle, whereas the α-form seems to be expressed predominantly in smooth muscle. The presence of low levels of the smooth muscle α-tropomyosin isoform in striated muscle indicates either tissue contamination from the vascular smooth muscle or a low level of expression of the smooth muscle isoform in the striated muscle cells. The fact that L_6E_9 myotubes produce both α_1- and α-tropomyosin mRNA favours the second possibility and demonstrates that striated and smooth muscle isoforms can be synthesized in the same cell. The striated muscle α-tropomyosin isoforms are also developmentally regulated. The α_1-tropomyosin mRNA is induced early in muscle development and accumulates to high levels in the adult, whereas α_2-tropomyosin mRNA can only be detected in adult skeletal and ventricular tissues (Fig. 3). These results also demonstrate that identical α-tropomyosin isoforms are expressed in skeletal and cardiac muscles, despite the fact that the two muscle types express different myosin heavy chains[31–33], light chains[34,35], actin[36] and troponins[37–39].

The results presented here shown the existence of three distinct α-tropomyosin mRNAs, all three of which share regions of 100% homology and isotype specific sequences. Such an arrangement suggests that the α-tropomyosin gene has an unusual organization with common and exchangeable exons that can be spliced together according to different combinatorial possibilities.

Restriction fragment length polymorphisms (RFLPs) of maternally inherited mitochondrial DNA have revealed that genetic exchanges can occur between populations, subspecies or even species[1-4]. From the point of view of population genetics the mammalian Y chromosome represents a genomic analogue of the mitochondrion; it is inherited only paternally and remains perpetually monosomic, showing little meiotic recombination with other chromosomes. Using a Y-specific genomic DNA probe obtained from a flow-sorted mouse Y-chromosome library, we have examined the RFLPs in 10 newly established mouse lines of the European semispecies *Mus musculus domesticus* and *Mus musculus musculus*[5], and identified two variant forms of the Y chromosome, each of which is characteristic of one of the semispecies. As reported here, probing the DNA from nine established inbred laboratory strains reveals that the strain SJL carries a *M.m. domesticus* type Y whereas, surprisingly, the Y chromosomes of the other eight strains are of *M.m. musculus* origin. Hence, these strains cannot be regarded as archetypes of *M.m. domesticus* as suggested by protein polymorphisms and mitochrondrial DNA sequence data, but rather as genetic hybrids between the two semispecies.

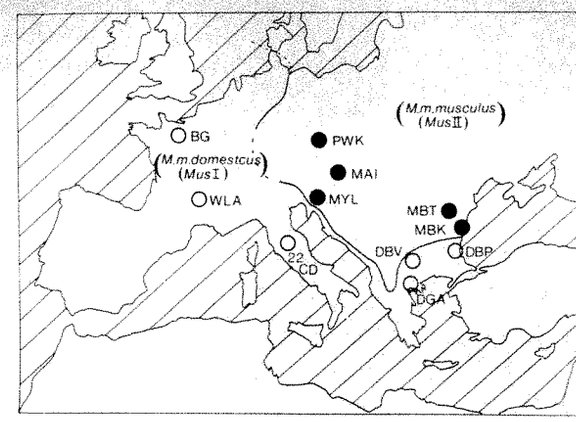

Fig. 1 Map of Europe showing the geographical origin of the 10 wild-derived strains of mouse studied. The two semispecies meet and hybridize along a narrow zone, indicated by the thick line, extending from Denmark, through central Europe to the Black Sea[2,4,5]. *M.m. domesticus* is found in western and southern Europe, *M.m. musculus* in central and eastern Europe. These semispecies have also been termed *Mus* 1 and *Mus* 2 (see ref. 5). The distribution of the two Y-chromosome haplotypes of these strains (indicated by solid and open circles) shows that each is specific to one of the semispecies.

Analysis of genetic variation in wild mouse populations affecting either nuclear genes (measured by protein polymorphisms) or maternally inherited cytoplasmic DNA (that is, mitochondrial DNA RFLPs) has revealed the existence of extensive polymorphism in most systems. These differential patterns allow a clear biochemical distinction to be made between different taxonomical units and show that a variety of interrelationships exist between the different groups[5]. In contrast, an analysis of the RFLPs of mitochondrial DNA in common inbred laboratory strains shows little variation, suggesting that these strains may in fact be derived from a single *M.m. domesticus* female lineage[6]. This implies that the extensive nuclear variation which exists, as evidenced by protein polymorphisms, could have been introduced through the males. One way to assess this contribution is to examine RFLPs of the mouse Y chromosome; this chromosome is unique in that normally it can be transmitted only via the male, it remains haploid in the genome and shows only a very limited amount of meiotic recombination with other chromosomes[7]. Polymorphisms characteristic of one population would therefore tend to become fixed on the Y chromosome.

We have shown recently that Y-specific DNA probes can be obtained from Y chromosome-enriched DNA libraries[8-10]. We have cloned two independent complementary DNA libraries from mouse metaphase chromosomes enriched for the Y chromosome by flow sorting according to the methods described by Baron *et al.*[11]. A random probe (pY353/B) consisting of a 1.5-kilobase (kb) fragment was isolated from one of these libraries; when used to probe *Eco*RI-restricted genomic blots from inbred male and female C57BL/6 mice under either stringent or non-stringent conditions, pY353/B hybridized with the male alone. In addition to the cognate 1.5-kb band, the probe detects four homologous bands of ~5, 7, 9.5 and 15 kb and therefore forms part of a small multi-sequence family. pY353/B reacts with the male teratocarcinoma cell line PCC7 but not with the male teratocarcinoma line PCC4 which has lost the Y chromosome during culture (data not shown). Therefore, we consider this probe to be Y chromosome-specific.

To assess the Y-chromosome polymorphisms that exist in the wild, we used a panel of DNAs from 10 newly established incipient inbred strains; these lines were derived from mice caught at the locations shown in Fig. 1 and subsequently inbred for a minimum of seven generations. The mice fall into the two well established European groups *M.m. domesticus* and *M.m. musculus*. These groups can be distinguished taxonomically or

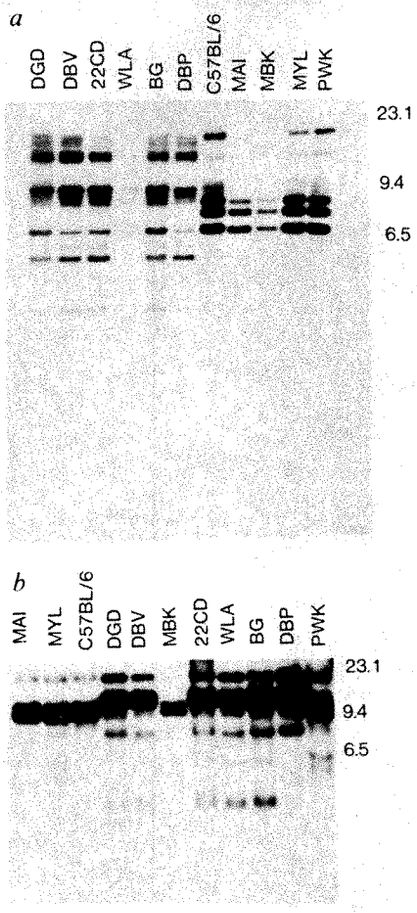

Fig. 2 Hybridization of pY353/B to DNAs from male mice. DNA was extracted from individual male mice and digested with either *Msp*I or *Hin*dIII. DNA (10 μg) was then separated on either 0.7% (*a*) or 0.8% (*b*) agarose gels and transfered to a Zetapore filter membrane. pY353/B was labelled to an approximate specific activity of 2×10^8 c.p.m. μg^{-1} with ^{32}P by nick-translation and used to probe the blots. Hybridization was at 42 °C for 16 h in 50% formamide, 5 × SSC. Blots were washed three times for 30 min each at 68 °C in 2 × SSC, 0.1% SDS, followed by three times for 30 min each at 68 °C in 0.1 × SSC, 0.1% SDS. Filters were then exposed to Kodak X-AR5 film for 16–20 h at −70 °C. Approximate sizes in kilobase (kb) are shown at the right. Mouse lines DGD, DBV, 22CD, WLA, BG and DBP are of *M.m. domesticus* type; lines MAI, MBK, MYL and PWK of *M.m. musculus* type. *a* (*Msp*I digestion) shows that laboratory strain C57BL/6 exhibits three bands of ~6.6, 7.0 and 8.0 kb characteristic of *M.m. musculus*. *b* (*Hin*dIII digest) again shows that C57BL/6 exhibits the *M.m. musculus* characteristic 10- and 12-kb bands. Re-probing the blots, after dehybridization, with a cloned mouse *H-2* cDNA probe showed that the lanes do not contain exactly equal amounts of DNA. The weaker signal seen with WLA results from underloading.

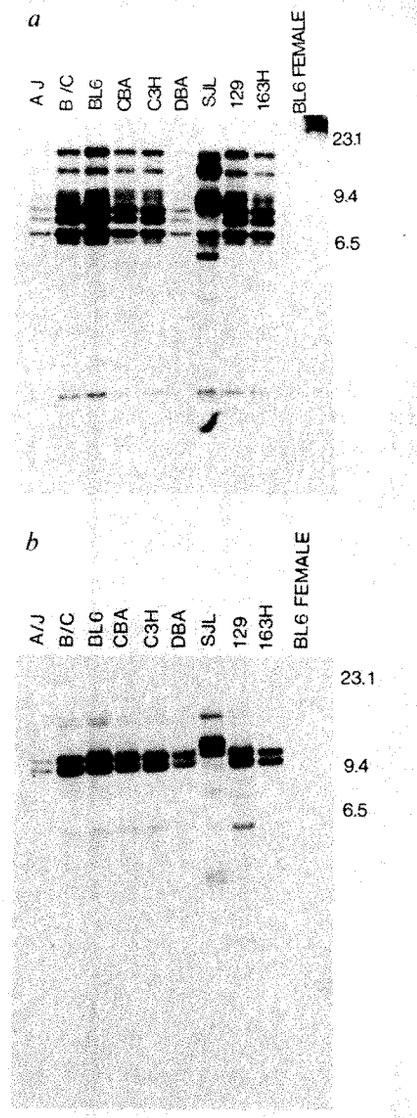

Fig. 3 Hybridization of pY353/B to genomic blots of nine established inbred laboratory mouse strains. Genomic blots were performed as described in Fig. 1 legend. The laboratory mouse strains are all maintained at the Institut Pasteur. Strains are (from left to right) A/J, BALB/c, C57BL/6, CBA/H, C3H, DBA/2, SJL, 129/sv, 163H and C57BL/6 female. Strain 163H is included as male fibroblasts from this line were used to flow-sort the Y (manuscript in preparation). *a*, The result of probing an *Msp*I genomic blot (0.8% agarose) with pY353/B. All strains tested show the characteristic *M.m. musculus* banding pattern except SJL, which shows the *M.m. domesticus* pattern. The result is confirmed by *b* (*Hin*dIII digest, 0.7% agarose) in which all strains show the typical *M.m. musculus* pattern except SJL, which shows the characteristic *M.m. domesticus* pattern of hybridization. Re-probing the blots with a cloned mouse *H-2* cDNA probe showed that the lanes contained equivalent amounts of DNA. Therefore, the weaker hybridization intensity seen in the A/J and DBA/2 tracts is not due to loading differences but probably represents variations in copy number.

more recently on the basis of multiple biochemical markers[5]; they are parapatric (*M.m. domesticus* is found in western and southern Europe, *M.m. musculus* in central and eastern Europe) and meet along a narrow hybridization zone[2,4]. We believe the two groups represent semispecies within the complex *Mus musculus* rather than subspecies, as important restrictions to genetic introgression reduce the hybrid zone to a narrow geographical area; this prevents the formation of a genetic continuum characteristic of subspecies interaction.

DNAs from single male and female mice were digested with *Eco*RI, *Taq*I, *Msp*I or *Hin*dIII, separated on agarose gels and transferred to a Zetapore membrane. pY353/B was labelled with ^{32}P by nick-translation and used to probe the genomic blots. After washing at 68 °C in 0.1 × SSC we detected no hybridization with any of the female DNAs (data not shown) whereas pY353/B hybridized to all male DNAs. No differences could be detected between any of the mice on the *Eco*RI or *Taq*I blots but a clear dimorphism was seen on either the *Msp*I or *Hin*dIII digests (Fig. 2*a*,*b*). Neither *Taq*I nor *Hin*dIII cuts within the probe whereas *Msp*I does. The polymorphic forms coincided exactly with the semispecies designation. All *M.m. domesticus* mice carried one form, *M.m. musculus* the alternative form. There was no significant variation within the two groups using either enzyme. Thus, this probe can be used to discriminate

between the Y chromosomes of *M.m. domesticus* and *M.m. musculus*. Surprisingly, the Y chromosome carried by the laboratory reference strain C57BL/6 showed the characteristic patterns of *M.m. musculus* on both the *Msp*I and *Hin*dIII digests. This finding was unexpected as it is generally assumed (and mitochondrial data support this assumption) that the laboratory strains were derived from *M.m. domesticus*.

To determine whether C57BL/6 is exceptional in this respect, we probed both *Hin*dIII and *Msp*I genomic blots of nine commonly used established inbred laboratory mouse strains with pY353/B. The polymorphic patterns obtained (Fig. 3*a*,*b*) show that the Y carried by SJL is of the *M.m. domesticus* type whereas all the other strains tested (A/J, BALB/c, C57BL/6, CBA/HeJ, C3H, DBA/2, 129/sv and 163H) are clearly *M.m. musculus*-derived. The latter strains of mice must therefore be considered as genetic hybrids between two semispecies, with the maternal contribution derived from *M.m. domesticus* and the paternal genetic information derived from *M.m. musculus*. Further genetic studies (which are in progress) should reveal the extent of the hybrid characteristics and show whether they are restricted to the Y chromosome or not. These data suggest that the Y-chromosome polymorphism involving SJL reported recently[12] may result from the semispecies origin of the Y and not strict intraspecies polymorphism. In fact, no Y-chromosome RFLPs were detected in the new wild-derived *M.m. domesticus* and *M.m. musculus* lines; this could be related to the nature of the probe as it has been shown that the highly repeated cloned Bkm probe[13] is extensively polymorphic both in wild and laboratory mouse strains (K. Jones, personal communication).

We consistently found that the intensity of hybridization of pY353/B to the A/J and DBA/2 inbred strains was 2–4 times less than that to the other strains, despite the blots containing approximately equal amounts of DNA from each mouse. As the hybridizations were performed under stringent washing conditions (0.1 × SSC, 68 °C), this difference probably represents a copy-number polymorphism rather than sequence divergence. Preliminary data using DNA from a mouse carrying a partially deleted Y chromosome (supplied by P. Burgoyne and E. Simpson) suggest that large blocks of DNA carrying this sequence are dispersed on the mouse Y chromosome (C.E.B., unpublished observations). It remains to be determined whether these copy-number polymorphisms arose during the establishment of the strains or whether they were present in the males which started the lines.

Historically, most of the laboratory mouse strains studied here (with the notable exception of SJL) are known to have originated from domesticated mice of North European and North American pet dealers and mouse fanciers. These mice were a mixture of locally caught North European (presumed *M.m. domesticus* origin) mice, subsequently carried across the Atlantic to North America, and imported 'fancy' Chinese and Japanese mice[14,15]. If the *M.m. musculus* type Y chromosome described here originated from the European mice it would imply that some *M.m. domesticus* wild mice carry the *M.m. musculus* Y chromosome. Although we have been unable to show any such exchanges in the wild mice studied so far, they mainly originate from South-East Europe where such exchanges might not occur. It is known that *M.m. domesticus* and *M.m. musculus* mice hybridize in Europe (Fig. 1) and that in Scandinavia and Denmark there is a considerable one-way mitochrondrial gene flow northeastwards from *M.m. domesticus* into *M.m. musculus*[2]. In the southeastern part of the hybrid zone this flow is reversed, occurring in the *M.m. musculus* to *M.m. domesticus* direction[4]. We are at present surveying a very large European mouse population to determine whether there is a Y-chromosome gene flow between the semispecies.

Alternatively, the *M.m. musculus* type Y could have been introduced through the Chinese or Japanese mice. In this regard, Bonhomme *et al.* have recently shown, using numerous biochemical markers, that the Asiatic subspecies *Mus musculus molossinus* (found in China and Japan) is closely related to *M.m. musculus*[5]. Mitochondrial DNA polymorphisms also support this view[6,16]. If this similarity extended to the Y chromosome, it could provide a simple explanation for the presence of a *M.m. musculus* type Y in the laboratory mouse strains, that is, being derived from the subspecies *M.m. molossinus*.

Whatever the origins of the Y chromosome, these data are of particular importance in studies involving hybrid genomes. Eicher *et al.* have reported that C57BL/6 differs from *M.m. domesticus* at an autosomal locus involved in gonadal determination and development (*tda*-1) as well as at the Y-localized testis-determining locus (*Tdy*)[17]. On the basis of the findings reported here, it seems probable that both *Tdy* and *tda*-1 in C57BL/6 have co-evolved from *M.m. musculus*. The partial or complete sex reversal reported can be interpreted as a result of the inability of a *M.m. domesticus* Y chromosome to interact with the *M.m. musculus tda*-1 locus. If this were true it would predict that the introduction of a Y from *M.m. musculus* into the C57BL/6 genome would not result in sex reversal, but the introduction of the SJL Y into the C57BL/6 genome would. Experiments are in progress to test this.

C.E.B. was in receipt of an INSERM Poste Orange grant. We thank Dr M. Goldberg and P. Metezeau for flow-sorting expertise, and acknowledge the support and advice of Drs M. Fellous, P. Avner, J. L. Guenet, P. Baldacci, G. Langsley, I. Garner and C. Rijnders.

Simian virus 40 enhancer increases number of RNA polymerase II molecules on linked DNA

Richard Treisman* & Tom Maniatis

Department of Biochemistry and Molecular Biology, Harvard University, 7 Divinity Avenue, Cambridge, Massachusetts 02138, USA

Since the discovery of transcription enhancer sequences in the genomes of the DNA viruses simian virus 40 (SV40)[1–3] and polyoma virus[4], these elements have been shown to play an important part in the control of both viral and cellular gene expression[5–10]. Enhancer elements act in *cis* to increase the amount of RNA produced from linked genes in a manner largely independent of distance and orientation[1–3,11,12]. The mechanisms by which enhancers act are not understood; in particular, it is not known whether the enhancer-dependent increase in the level of stable RNA reflects an increase in the rate of transcription. To address this question, we have used an *in vitro* nuclear transcription assay[13,14] to examine the effect of the SV40 enhancer on transcription of cloned human β-globin genes transiently introduced into HeLa cells[15]. We show here that the SV40 enhancer acts at least in part to increase the number of RNA polymerase II molecules transcribing the linked gene.

* Present address: MRC Laboratory for Molecular Biology, Hills Road, Cambridge CB2 2QH, UK.

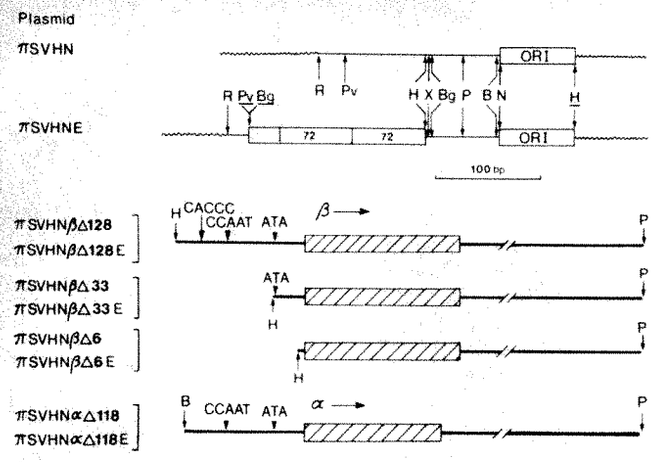

Fig. 1 Maps of the α- and β-globin gene plasmids used in HeLa cell transfection studies. Plasmids were constructed by standard procedures using the πVX miniplasmid as the parental plasmid[16,25]. The two miniplasmids πSVHN (no enhancer) and πSVHNE (with enhancer) are shown at the top of the figure. Open boxes represent SV40 sequences, with the origin of DNA replication (ORI) and the enhancer sequence (72-bp repeat) indicated. The enhancer fragment contains SV40 nucleotides 272 (*Pvu*II site converted by *Bgl*II linker) to 100 (*Xho*I linker converted to *Hin*dIII). The πVX plasmid vector sequences are shown as wavy lines, the polylinker as thin lines. The human β- and α-globin genes used are shown at the bottom, with the exons indicated by the shaded boxes, and introns and flanking sequences by thick lines. The β-globin promoter elements CACCC, CCAAT and ATA[18,19] are indicated. The β-globin plasmids lacking the SV40 enhancer, πSVHN$\beta\Delta$128, πSVHN$\beta\Delta$33 and πSVHN$\beta\Delta$6, and the enhancer-containing β-globin plasmids πSVHN$\beta\Delta$128E, πSVHN$\beta\Delta$33E and πSVHN$\beta\Delta$6E contain the β-globin genes on a *Hin*dIII-*Pst*I fragment inserted between the corresponding sites in the polylinker sequences of πSVHN and πSVHNE. The β-globin deletion mutants were constructed as described previously[22,26], and contain 128, 33 and 6 bp of 5′ flanking sequence of the β-globin gene. The α-globin plasmids πSVHN$\alpha\Delta$118 and πSVHN$\alpha\Delta$118E were constructed by inserting the *Bam*HI (artificially introduced at position −118) to *Pst*I fragment of the human α_1-globin gene between the *Bgl*II and *Pst*I sites of the two miniplasmids. The locations of relevant restriction enzyme cleavage sites are shown: R, *Eco*RI; Pv, *Pvu*II; H, *Hin*dIII; X, *Xba*I; Bg, *Bgl*II; P, *Pst*I; B, *Bam*HI; N, *Nco*I; sites underlined were destroyed during plasmid construction.

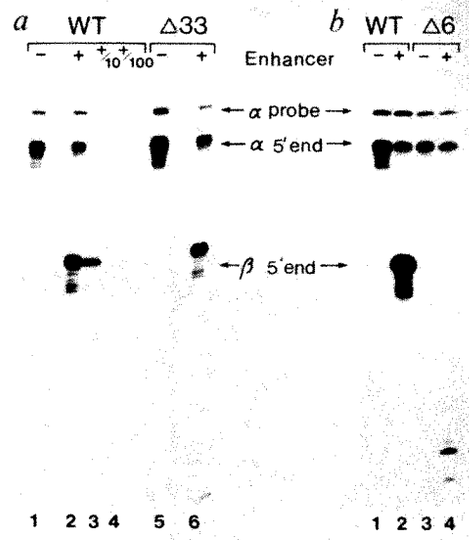

Fig. 2 Effect of the SV40 enhancer on the amount of accurately transcribed β-globin RNA in transfected HeLa cells. HeLa cells were transfected with 20 μg of plasmid DNA per 9-cm dish and the RNA was analysed by S_1 nuclease mapping procedures[27]. Each transfection included an equal mass of a human α-globin gene plasmid to serve as an internal reference. Unless otherwise stated, 40 μg of total cell RNA was used for each assay. The positions of nuclease-resistant DNA fragments mapping the 5′ ends of correctly initiated globin transcripts are indicated; − or + indicates the absence or presence, respectively, of the SV40 enhancer on the β-globin plasmid. The plasmids used contain β-globin genes with 128 (WT), 33 (Δ33) and 6 (Δ6) bp of 5′ flanking sequence. ***a***, Effect of the SV40 enhancer on the $\beta\Delta$128 (intact promoter) and Δ33 (deleted upstream element) β-globin genes. The α-globin plasmid πSVHSα1 (ref. 15), which does not contain an SV40 enhancer, was used as a reference. Lane 1, plasmid πSVHN$\beta\Delta$128; lane 2, plasmid πSVHN$\beta\Delta$128E; lane 3, plasmid πSVHN$\beta\Delta$128E, but the hybridization included only 4 μg of RNA; lane 4, 1/10 of the S_1 nuclease-resistant counts loaded in lane 3; lane 5, plasmid πSVHN$\beta\Delta$33; lane 6, plasmid πSVHN$\beta\Delta$33E. In lanes 3 and 5, the α-globin probe was omitted from the hybridization reaction. ***b***, Effect of the SV40 enhancer on the $\beta\Delta$128 (intact promoter) and $\beta\Delta$6 (no promoter) globin genes. The α-globin gene plasmid πSVHPα2 (ref. 26), which contains an SV40 enhancer, was used as an internal reference. Lane 1, plasmid πSVHN$\beta\Delta$128; lane 2, plasmid πSVHN$\beta\Delta$128E; lane 3, plasmid πSVHN$\beta\Delta$6; lane 4, plasmid πSVHN$\beta\Delta$6E. RNA which apparently initiates within the 5′-noncoding region of the gene is indicated by the arrows to the right of lane 4. Cell culture, DNA transfection and S_1 nuclease mapping procedures have been described previously[15,28]. The single-stranded [5′-^{32}P]-labelled probes were: β-globin, *Hae*III-*Mst*II*, nucleotides −76 to +70; α-globin, *Hha*I (artificially constructed; R.T., unpublished) to *Bss*HII*, nucleotides −11 to +97.

We first evaluated the effect of the SV40 enhancer on the accumulation of β-globin RNA using the S_1 nuclease mapping procedure. HeLa cells were transfected with plasmids carrying a human β-globin gene[15,16] with or without the SV40 enhancer (Fig. 1), and stable RNA was analysed 48 h after transfection. The DNA fragment containing the enhancer does not include sequences sufficient for SV40 early or late promoter function. As an internal reference, a plasmid containing the human α-globin gene was also included in the transfection mix. Figure 2*a* shows that the presence of the SV40 enhancer next to the intact β-globin promoter increases the amount of correctly initiated RNA produced by two to three orders of magnitude[1,16] (compare lane 1 with lanes 2–4).

We next isolated nuclei from transfected cells and incubated them with ^{32}P-labelled ribonucleoside triphosphates under conditions in which only limited elongation of previously initiated RNA chains occurs[13] (see Fig. 3 legend). The amount of *in vitro*-synthesized, labelled RNA specific for the α- or β-globin genes or vector DNA was determined by hybridization of partially fragmented RNA to a large excess of double-stranded DNA fragments immobilized on nitrocellulose[14,17]. The amount of radioactive RNA that hybridizes to a given fragment reflects the number of previously initiated RNA polymerase molecules present on the corresponding region of the transfected plasmid DNA[14]. The results of such a nuclear transcription experiment are shown in Fig. 3; in this experiment HeLa cells were transfected with β-globin plasmids that differ by the presence or absence of the SV40 enhancer sequence, together with a plasmid containing the human α-globin gene as an internal reference. Both globin and vector-specific RNAs were readily detectable after *in vitro* elongation of preinitiated RNA, and a substantial increase in the amount of β-globin specific RNA was observed when the gene was linked to the enhancer (Fig. 3*a*, compare lanes 1 and 2). A similar effect was observed with the α-globin gene using the β-globin plasmid as an internal reference (Fig. 3*a*, compare lanes 2 and 3). Examination of stable RNA showed that in the absence of a linked enhancer, the α-globin gene produced readily detectable levels of correctly initiated RNA, and that the presence of the enhancer at the 5′ side of the gene resulted in a 30–50-fold increase in the amount of RNA produced (data not shown). When 2 μg ml^{-1} α-amanitin was included in the nuclear transcription reaction, no globin- or vector-specific transcripts were synthesized (Fig. 3*b*, compare

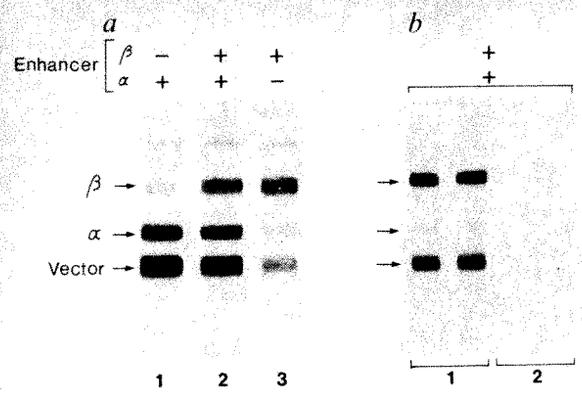

Fig. 3 Effect of the SV40 enhancer on nuclear transcription of transfected α- and β-globin plasmids. Each 'lane' is an autoradiogram of a nitrocellulose strip carrying fragments of β-globin, α-globin or vector DNA, after hybridization to RNA synthesized *in vitro*. The identities of the fragments and the presence (+) or absence (−) of the SV40 enhancer on each of the transfected plasmids are indicated. *a*, Effect of the SV40 enhancer on α- and β-globin nuclear transcription. HeLa cells were transfected with the following plasmids: lane 1, πSVHNβΔ128 + πSVHNαΔ118E; lane 2, πSVHNβΔ128E + πSVHNαΔ118E; lane 3, πSVHNβΔ128E + πSVHNαΔ118. *b*, Effect of α-amanitin on nuclear transcription of transfected plasmids. HeLa cells were transfected with πSVHNβΔ128E and πSVHPα2 (ref. 26), and nuclear transcription reactions performed either in the absence (lane 1) or presence (lane 2) of 2 μg ml^{-1} α-amanitin. Duplicate strips are shown.

Methods. Nuclei were isolated by hypotonic lysis using a Dounce homogenizer (type A pestle) as described previously[13]. Cell lysis was evaluated by Trypan blue staining. Nuclei from two 9-cm plates of transfected cells were used for each reaction. Isolated nuclei were resuspended at 0 °C in a total volume of 100 μl, comprising 50 μl 2 × transcription buffer[13] (50 mM dithiothreitol, 180 mM KCl, 10 mM $MgCl_2$, 20 mM Tris-HCl, 50% glycerol, *p*H 7.8), brought to 0.25 mM ATP, 0.125 mM GTP, 0.125 mM CTP. 100 μCi [α-^{32}P]UTP (410 Ci mmol^{-1}; Amersham) was added to each reaction. The nuclei were incubated at 37 °C for 5 min; no incorporation occurred after this time. Under these conditions, pre-initiated RNA chains are elongated by 300–500 nucleotides[13]. RNA was isolated by protease K treatment, followed by two extractions with phenol/chloroform as described previously[27]; residual DNA was removed by treatment with RNase-free DNase. Approximately 5×10^6 to 10^7 c.p.m. RNA were routinely obtained. Fragmentation of RNA by partial alkali hydrolysis was as described elsewhere[29]. For analysis of the *in vitro*-synthesized RNA by strip blot hybridization[14], plasmids πSVHNβΔ128 and πSVHNαΔ118 (25 μg each) were digested with *Xba*I and *Pst*I and the fragments resolved on a 10 cm-wide 1.2% agarose gel, then transferred to nitrocellulose[30]. Duplicate 1 cm-wide strips of nitrocellulose were then hybridized to equal numbers of counts as described[40], washed, and exposed to Kodak X-AR5 film.

lanes 1 and 2), indicating that the *in vitro* transcription is due to RNA polymerase II. We also verified that reinitiation does not occur in the system by performing nuclear incubations in the presence of 0.5% sarkosyl or 1 mg ml^{-1} heparin. Although these additions slightly diminished the total *in vitro* RNA synthesis, little effect on *in vitro* synthesis of α- and β-globin specific RNA was observed (data not shown).

These results demonstrate that the SV40 enhancer causes a substantial increase in the number of RNA polymerase II molecules present on linked DNA. However, the experiment does not distinguish between *in vitro* elongation of transcripts initiated at the β-globin promoter and the elongation of nascent transcripts initiated at other sites in the plasmid DNA. To address this problem, we examined the effect of promoter deletions on β-globin gene specific transcription in isolated nuclei. Plasmids were constructed in which the enhancer is located at the 5′ side of truncated β-globin genes containing either 33 base pairs (bp) of 5′ flanking sequence (which includes the ATA box, but lacks the upstream promoter elements CACCC and CCAAT[18,19]), (plasmids πSVHNβΔ33 and πSVHNβΔ33E; Fig. 1) or only 6 bp of 5′ flanking sequence (which lacks all promoter elements), (plasmids πSVHNβΔ6 and πSVHNβΔ6E; Fig. 1). The transcription of these plasmids in transfected HeLa cells was then analysed by S_1 nuclease mapping and by the nuclear transcription assay. The S_1 analysis (Fig. 2) shows that (1) neither of the truncated β-globin genes directs the synthesis of detectable levels of correctly initiated β-globin RNA in the absence of a linked SV40 enhancer sequence (Fig. 2*a*, lane 5; Fig. 2*b*, lane 1); (2) deletion of sequences 5′ to the ATA box has essentially no effect on the level of correctly initiated RNA produced when the enhancer is in close proximity to the ATA box, indicating that the enhancer can compensate for the deletion of upstream promoter sequences as reported previously for other promoters[20,21] (Fig. 2*a*, lane 6). (We note, however, that when the SV40 enhancer is located farther upstream from the βΔ33 gene, or on its 3′ side, virtually no transcription is observed[22].) (3) Deletion of all promoter elements results in the loss of correctly initiated β-globin RNA and the concomitant appearance of a small amount of RNA that is apparently initiated at, or spliced to, sites in the 5′-untranslated region of the gene (Fig. 2*b*, lane 4).

Figure 4 shows a nuclear transcription analysis of the β-globin promoter deletions. The RNA synthesized *in vitro* was hybridized to the separate strands of the β- and α-globin genes cloned into M13mp8. The linkage of the SV40 enhancer to the intact β-globin gene increases specifically the amount of transcription of the coding (or 'anti-sense') DNA strand (Fig. 4*a*, compare strips 1, 2 with 3, 4). A small amount of transcription of the noncoding strands of both β- and α-globin genes was detected, even in the absence of a linked SV40 enhancer. We also observed a decrease in the number of RNA polymerase molecules on the α-globin reference gene when the test β-globin gene was linked

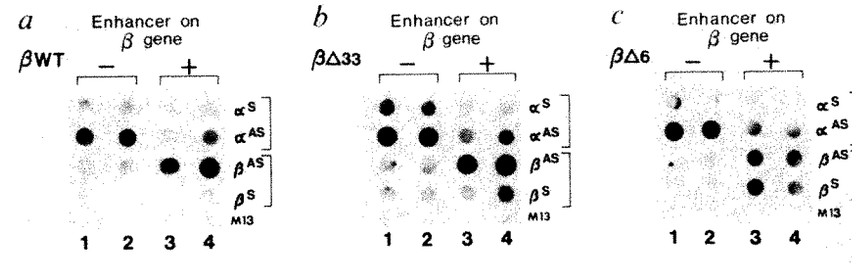

Fig. 4 Effect of the SV40 enhancer on nuclear transcription of β-globin promoter deletion mutants. Each panel contains pairs of duplicate strips of dot blots on which are spotted recombinant M13 phage carrying the sense (S) and anti-sense (AS) strands of the α- and β-globin genes. Bona fide transcripts hybridize with the anti-sense strand. HeLa cells were transfected with πSVHPα2 (ref. 26) and *a*, plasmid πSVHNβΔ128 (strips 1, 2) or πSVHNβΔ128E (strips 3, 4); *b*, πSVHNβΔ33 (strips 1, 2) or πSVHNβΔ33E (strips 3, 4); *c*, πSVHNβΔ6 (strips 1, 2) or πSVHNβΔ6E (strips 3, 4).

Methods. Nuclear transcriptions, RNA preparation and hybridization conditions were as described in Fig. 3 legend. Recombinant M13 phage were constructed by insertion of the 1.5-kb *Pst*I fragment of the human α_1-globin gene, or a 2.2-kb *Pst*I fragment of the human β-globin gene (from a *Pst*I linker at the endpoint of the −33 deletion to the *Pst*I site 500 bp on the 3′ side of the gene) into M13mp8 in either orientation, by standard procedures. The M13 DNAs (5 μg) were spotted onto nitrocellulose in 10 × SSC with a 'Manifold' apparatus (Schleicher & Schuell).

to the enhancer, suggesting that co-transfected enhancers can compete for limiting factors in the *in vitro* transcription assay. We do not observe this effect at the level of stable RNA under our conditions, indicating that factors that may be limiting *in vitro* are not limiting *in vivo*. Others have reported enhancer competition *in vivo* using different transcription units and transfection conditions[23]. In agreement with the observation that deletion of the β-globin upstream elements in plasmid πSVHNβΔ33E does not affect the accumulation of stable RNA, we find that the behaviour of this plasmid in the nuclear transcription assay is identical to that observed with the plasmid carrying the intact β-globin gene (Fig. 4, compare *a* and *b*). A strikingly different result was obtained when all the β-globin promoter elements were removed (Fig. 4*c*). Again, a small amount of *in vitro* transcription of both strands of the truncated gene was detected even in the absence of a linked enhancer sequence. However, linkage of the SV40 enhancer sequence to the gene lacking promoter elements resulted in a small increase in transcription of both DNA strands (Fig. 4*c*, compare strips 1, 2 with 3, 4); this increase may result from the activation of normally silent 'cryptic' start sites such as that observed in the 5′-untranslated region of the β-globin gene (Fig. 2*b*, lane 4). We conclude that enhancer effects seen in the nuclear transcription assays do depend on known promoter elements of the β-globin gene, and therefore relate to the production of bona fide β-globin RNA.

We have demonstrated here that the SV40 enhancer causes an increase in the number of RNA polymerase II molecules engaged in the transcription of linked DNA. The increase is dependent on known components of the β-globin gene promoter[18,19]. It was reported previously that deletion of the adenovirus 2 E1A enhancer causes a reduction in synthesis of E1A RNA measured in pulse labelling experiments[24]. Our observations exclude the possibility that the enhancer acts solely to allow stabilization of nascent transcripts. The magnitude of the enhancer effect observed in the nuclear transcription assay appears to be smaller than the two to three orders of magnitude effect on the level of stable RNA (compare Figs 2 and 3). Moreover, the 10-20-fold difference in the effect of the SV40 enhancer on the production of stable α- and β-globin RNA[15] is apparently not observed in the nuclear transcription assay. However, accurate quantitation of enhancer effects in the *in vitro* nuclear transcription assay is difficult. At least some of the low level of α-globin nuclear transcription observed in the absence of a linked enhancer sequence (Fig. 3*a*) must be due to elongation of correctly initiated RNA, as this plasmid does produce easily detectable levels of stable α-globin RNA (data not shown; see ref. 15). It is possible, however, that the low level of β-globin nuclear transcription observed in the absence of a linked enhancer does not represent elongation of RNA initiated at the correct β-globin cap site. This possibility is suggested by the observation that nuclear transcription in the absence of the enhancer is not significantly dependent on the β-globin promoter (Fig. 4, compare *a* and *c*). The magnitude of the effect we observe therefore provides a minimum estimate of the actual effect of the enhancer on polymerase loading. We cannot exclude the possibility that the enhancer also acts at levels other than transcription initiation to increase the production of stable RNA.

Simian virus 40 enhancer increases RNA polymerase density within the linked gene

Frank Weber & Walter Schaffner

Institut für Molekularbiologie II der Universität Zürich, Hönggerberg, CH-8093 Zürich, Switzerland

Enhancers are regulatory DNA elements, usually about 200 base pairs (bp) long, which are able to stimulate transcription of linked genes in eukaryotic cells[1,2]. This activation can be exerted over large distances, and from a position 5′ or 3′ to the gene[1]. Enhancers have been identified in viral genomes[1-9] and cellular genes[10-15]. Using a transient expression assay, we have analysed transcription of the rabbit β-globin gene and the thymidine kinase gene from herpes simplex virus with and without a simian virus 40 (SV40) enhancer. S_1 nuclease mapping shows a high level of specific transcripts when the genes are linked to the enhancer. To determine whether this increased number of transcripts is due to a higher transcription rate, or perhaps to a shift from nonspecific to specific initiation, we have performed run-on transcription assays with isolated nuclei. Our results, presented here, demonstrate that the SV40 enhancer increases the RNA polymerase density within the linked gene. Therefore, enhancers apparently increase the rate of transcription initiation without influencing the specificity of initiation.

To study the enhancer effect on polymerase II transcription units, we constructed clones containing the rabbit β-globin gene and the herpes simplex virus (HSV) thymidine kinase (*tk*) gene with and without the SV40 enhancer (see Fig. 1).

The rabbit β-globin and the HSV *tk* genes, which were previously shown to respond to an enhancer[1,8], were cloned as 2-kilobase (kb) fragments into the plasmid pUC9 (ref. 16). The SV40 72-bp repeat enhancer was cloned as a 195-bp fragment[17,18] ~1.5 kb downstream of the respective promoters.

To demonstrate enhancer-dependent expression of the two genes, we transfected the clones into human HeLa cells, using the calcium phosphate co-precipitation method[18,19]. RNA was extracted after 2 days and analysed by S_1 nuclease mapping. The S_1 analysis clearly shows that the enhancer stimulates the level of transcription of the β-globin and *tk* genes ~40-fold and 15-fold, respectively (Fig. 2). The effect on β-globin transcription, however, is less pronounced than in previous experiments in which stimulation by the SV40 enhancer was ~200-fold[1]. This difference results mainly from an increased level of transcripts in the absence of an enhancer when using the pUC vector instead of the previously used pBR322 (data not shown), and was not analysed further.

An analysis of both the 5′ and 3′ ends of the rabbit β-globin transcripts demonstrates correct initiation, 3′ processing and

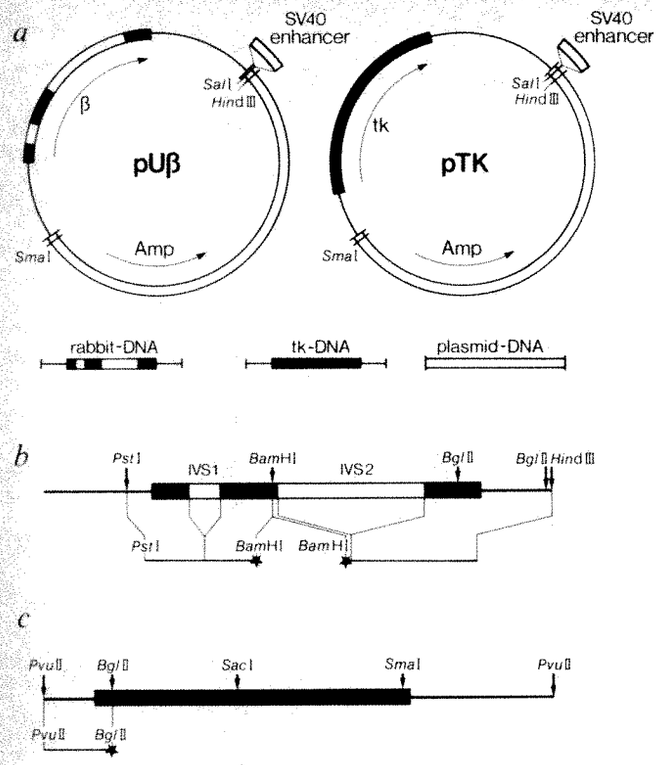

Fig. 1 Maps of recombinant DNAs and schematic representation of the S_1 nuclease mapping probes used. *a*, pUβ: the 2-kb *Bgl*II fragment of the rabbit β_1-globin gene[29] was cloned into the *Bam*HI site of pUC9 (ref. 16) so that the direction of transcription of the globin gene was opposite to that of the *lacZ* gene contained in the plasmid. pTK: the 2-kb *Pvu*II fragment of the HSV *tk* gene[30] was first subcloned into the polylinker of pUC8 and thereafter excised as a *Bam*HI fragment for insertion into pUC9. The clones containing a 195-bp insert of the SV40 enhancer[17,18] were called pUβE and pTKE, respectively. *b*, A β-globin gene lacking both intervening sequences was used to prepare the radioactive probes. To map β-globin transcripts, DNA was end-labelled at the *Bam*HI site using either T4 polynucleotide kinase (for 5′-specific probe) or the Klenow fragment of DNA polymerase I (3′-specific probe). *c*, DNA was labelled at the *Bgl*II site to obtain a 5′-specific *tk* gene probe.

Methods. Tissue culture cell lines were grown and transfected as described previously[18]. As a control for transfection efficiency, a 'tracer' gene was added to one of two duplicate plates: (1) A clone containing the SV40 T-antigen gene under the control of the adenovirus major late promoter and an SV40 enhancer was mixed 1 : 100 with the appropriate β-globin clone. Two days post-transfection, the cells in the plate co-transfected with tracer were fixed and stained for T-antigen by immunofluorescence. (2) The cells in the plate without tracer were collected for RNA extraction. Similar numbers of stained nuclei were observed independent of the globin construct used (523 T-antigen-positive per 14,000 cells and 509 positive per 13,000 cells with pUβ and pUβE, respectively). This finding was corroborated by Southern blot analysis of nuclear DNA from transfected HeLa cells, which yielded equal amounts of cloned DNA present within the nuclei (not shown). RNA analysis was performed as described elsewhere[31,32]. End-labelled single-stranded DNA (see Fig. 1*b*, *c*) was hybridized to unlabelled RNA, treated with S_1 nuclease, denatured, fractionated by gel electrophoresis and autoradiographed.

splicing of the two introns during maturation of messenger RNA, independent of whether an enhancer was present or not (Fig. 2*a*, *b*). Also, the *tk* mRNA expressed from pTK and pTKE has a correct 5′ end (Fig. 2*c*). The enhancer, therefore, does not apparently influence the specificity of initiation or the processing of the pre-mRNAs.

However, S_1 nuclease analysis measures only the steady-state level of stable transcripts. In particular, the presence of a clean S_1-protected band does not rule out the possible existence of a wealth of nonspecific unstable transcripts from the same gene.

To determine whether an enhancer shifts the equilibrium from nonspecific to specific transcripts[20], or whether it increases the rate of gene transcription, we measured the RNA polymerase II density. To this end, we have determined the enhancer effect by a run-on transcription experiment in isolated nuclei[21,22]; this technique is widely used to determine the polymerase density on an endogenous gene of defined copy number.

It is known that the enhancer effect is not due to differential uptake of the DNA[1]; in particular, the effect is also seen when defined numbers of molecules are injected into cells[2,8] and when template molecules with and without enhancer are replicated to high copy numbers using COS cells (refs 20, 23, 24 and T. Gerster and W.S., unpublished). Therefore, the run-on technique is also applicable to the study of transcription in a transient assay[25]. The combination of the transient expression system with a nuclear run-on assay offers several advantages: for example, the rate of transcription within different cloned and mutagenized genes can be compared, which is particularly useful with mutants possibly affecting mRNA stability or transcription termination of mRNA (for the latter case see below and Fig. 3).

Nuclei of HeLa cells transfected with our β-globin and *tk* clones were isolated and digested with RNase A. Pre-initiated RNA was then elongated *in vitro* for 10 min in the presence of [α-^{32}P]rGTP, giving rise to labelled RNA molecules ~200–300 nucleotides long (Fig. 3*a*). As RNA polymerase II appears to protect ~60 nucleotides from nuclease digestion, the *in vivo* elongation rate is ~15–20 nucleotides per min in HeLa nuclei; this rate is much lower than that found *in vivo* but is in good agreement with previous *in vitro* studies[22,26].

The labelled RNA was then hybridized to dot-blots of cloned DNA. The dot hybridization signals in the run-on assays are

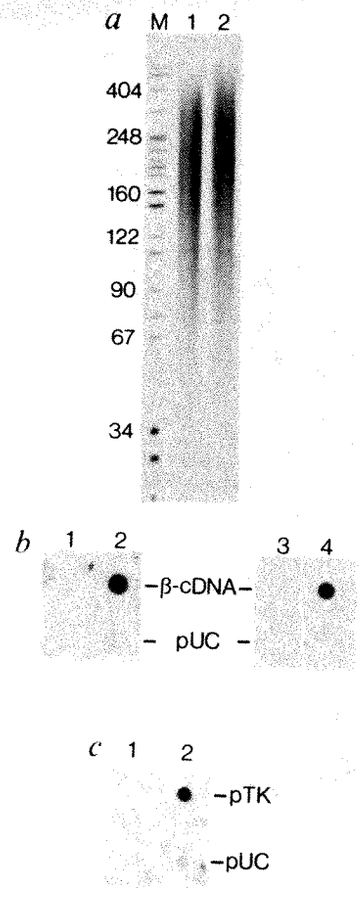

Fig. 3 Run-on assays also reveal the enhancer effect. *a*, RNA from nuclei which had been treated with RNase A and labelled *in vitro* was isolated and subjected to denaturing polyacrylamide (6%) gel electrophoresis. Cells transfected with pUβ (lane 1) and pUβE (lane 2) show a similar size distribution of *in vitro* elongated nuclear RNA; M, end-labelled marker DNA fragments (pBR322 cleaved with *Hpa*II). *b*, Unlabelled DNA of pUC9 and pcβ (rabbit β-globin cDNA) was denatured, spotted onto nitrocellulose membrane and hybridized to 4×10^6 c.p.m. (lanes 1 and 2) or 1.2×10^6 c.p.m. (lanes 3 and 4) of nuclear RNA from cells transfected with: pUβ (lane 1); pUβE (lane 2); pUβ linearized with *Hin*dIII (lane 3); pUβE linearized with *Hin*dIII (lane 4). *c*, Hybridization of pUC and pTK DNA to 6×10^6 c.p.m. of *in vitro* elongated nuclear RNA from cells transfected with pTK (lane 1) and pTKE (lane 2). HeLa cells were transfected as described previously[18]. The nuclei were isolated 36 h post-transfection as described[21], except that divalent cations were omitted from the buffers. Run-on assays were performed as published elsewhere[22].

expected to be proportional to the polymerase densities as RNase A treatment of the nuclei before *in vitro* elongation removes the pre-existing different amounts of unlabelled RNA and thus avoids competition of the mature mRNA with nascent transcripts[22]. We found that nuclear RNA from cells transfected with pUβE or pTKE hybridizes strongly to rabbit β-globin complementary DNA or *tk* DNA, respectively, whereas nuclear RNA from pUβ- or pTK-transfected cells hybridizes only weakly (Fig. 3*b*, *c*), in agreement with the S_1 nuclease mapping assays shown in Fig. 2.

The nuclear RNAs hybridize ~10% as strongly to plasmid vector DNA as β-globin or *tk* gene sequences (Fig. 3*b*, *c*), indicating (1) that the enhancer primarily stimulates transcription from the β-globin or *tk* promoter rather than from pseudopromoters within plasmid sequences, and (2) that there is efficient transcription termination preventing readthrough into plasmid DNA.

In agreement with our S_1 nuclease mapping data (Fig. 2), similar results were obtained whether transfection was performed using circular or linear DNA (Fig. 3*a*, *b*; the latter is probably ligated within the transfected cells[18]).

Thus, our results indicate strongly that an enhancer increases the RNA polymerase II density on a gene to which it is linked, that is, the enhancer facilitates transcription by increasing the frequency of initiation. In particular, the enhancer does not seem to shift the equilibrium from nonspecific to specific transcripts, as could have been inferred from the work of Humphries *et al.*[20]. These authors studied the expression of human α-, β- and δ-globin genes using vectors containing an SV40 replicon[27] and were struck by the high levels of nonspecific transcripts in the absence of an enhancer. However, we consider it likely that the high level of nonspecific β-globin transcripts is a peculiarity of their assay conditions. With replicating SV40 templates, there can be a considerable fraction of nonspecific transcripts from multiple scattered initiation points[24] which are perhaps related to the multiple initiation sites of SV40 late transcripts[28].

We thank Ueli Schibler (Epalinges) for technical advice, Fritz Ochsenbein for preparing the graphs, and Maria Jasin and Max L. Birnstiel for critical reading of the manuscript. This work was supported by the Kanton of Zürich and the Swiss National Research Foundation.

Tests of influence

P.E. Bryant

Beyond IQ: A Triarchic Theory of Human Intelligence.
By Robert J. Sternberg.
Cambridge University Press: 1985. Pp.411. Hbk £25, $39.50; pbk £8.95, $14.95.

A PARADOX touches the study of intelligence. The subject is controversial — so controversial that it would be difficult to find even two psychologists who completely agree with each other on the nature of intelligence. Yet the psychologists' work in this area has had more impact outside the laboratory than anything else that has interested them, success which has merely increased the controversy. My own suspicion is that, if it were not for the obvious practical uses of these omnipresent tests, psychologists would have given up asking themselves about the underlying nature of intelligence as a far too abtruse and unrewarding question many years ago. But the very fact that the tests work, and that they seem to measure something which could reasonably be called intelligence, has posed a question which many have found impossible to resist investigating and trying to answer.

Robert Sternberg is the latest and almost certainly the most energetic in a long line of people who have devoted their time to attempting to say what intelligence means and what is responsible for intelligent behaviour. His approach is inclusive, and has become more so over the years. In this book, which is not his first on the subject, he sets out to combine three different approaches in what he calls a "triarchic" theory of intelligence. In order to understand why these three approaches have, on the whole, not been combined in the past, one needs to know something of the history of the study of intelligence.

It goes back to the first two pioneers of the intelligence test: Galton, whose tests were not a success, and Binet who, in contrast, produced the first effective intelligence test which has influenced every such test devised since then. The reasons for Galton's failure and Binet's success are important. Galton adopted a theoretical approach: he decided that intelligence consists of this and that ability and then produced tests to measure them. One test, for example, measured the speed of people's movements, another how well they named colours. These tests were certainly measures in the sense that different people produced different scores on them, but they did not measure intelligence. It soon turned out that they bore no relation to educational attainment, and that made it difficult to believe that they had anything to do with intellectual capacity.

Binet, too, had his theories, as Sternberg notes, but he did not let them play much part in his tests. His approach was pragmatic, and he had one clear guideline. Whatever intelligence is, he argued, it increases during childhood. So he only accepted tests which older children were more likely to answer correctly than were younger ones. This approach worked. Binet's test did predict reasonably well how children would manage at school, and every other intelligence test since then has had a strong, though never perfect, relation to educational achievements.

But this practical success left an arresting theoretical vacuum. The tests themselves did little to reveal the underlying nature of intelligence. In the following 50 years or so the main attempts to fill this gap were made by people who used factor analysis as their main tool and their answers were distinctly uninspiring. They looked rather like the first part of a cooking recipe; intelligence was held to consist of this factor and this one and so on, and there was no sense of a system that actually worked. Sternberg gives reasonably short shrift to these theories. He is concerned with the workings of intelligence.

This is not at all surprising since Sternberg comes from a tradition in psychology which developed quite separately from the intelligence testing movement and which originally had nothing to do with individual differences. The study of information processing is concerned with the underlying processes involved in taking in, remembering and coordinating information about the environment, and its subject matter goes from the simplest kind of remembering or attention through to complex logical processes such as making sophisticated analogies or drawing inferences. Sternberg has always argued that this is the stuff of intelligence, and most of his work has taken the form of forging links between studies of information processing and studies of differences in intelligence.

But now he thinks that this is not enough. His "triarchic" model is really a model of how to approach the question of intelligence rather than a fully fledged theory about intelligence. He argues that we need to know not only about the components of intelligence (the information processing involved) but also about the role of experience (particularly about the way that skills become automatic after a while) and, as well, about the context in which intelligent behaviour takes place. These three kinds of question are Sternberg's triarchy and the first half of the book is a convincing argument that all three are needed. In the second half he deals with particular problems which have always been closely associated with the study of intelligence, many of which — such as syllogisms and analogies — crop up a great deal in intelligence tests. His aim is to subject them to his triarchic approach, but here the analysis is often uneven though it is always very detailed. Sternberg's "componential" leanings take over. There is little in this part of the book about either context or the effects of experience. Sternberg has more research to do on these two questions, but given his phenomenal productivity there seems little doubt that he will manage it.

In the end the proof of Sternberg's pudding will be the same as it was with Galton's and Binet's. His scheme will only influence people outside the world of psychology, and to a great extent within it too, if it manages to produce good, new tests. Only then can we be sure that his scheme transcends the laboratory in a way that Galton's so signally did not. Sternberg seems to recognize this when at the end of the book he suggests several ways of improving tests of intelligence. He should try these out. In the meantime he has written an attractive and valuable account of the long and successful enterprise which began so well with Binet and still seems to be in very good hands. □

P.E. Bryant is Watts Professor of Psychology at the University of Oxford.

Upright education — the Geradhalter, *an invention of a nineteenth-century educator, one Dr Schreber, intended to improve children's posture by discouraging them from slumping forward Schreber used this and similar devices on his own children, one of whom was mentally deranged for most of his adult life. The illustration is taken from Robert Trivers's* Social Evolution, *published by Benjamin/Cummings.*

On the rocks down under

Michael Audley-Charles

Phanerozoic Earth History of Australia.
Edited by J.J. Veevers.
Clarendon: 1985. Pp.418. £55, $75.

REGIONAL geology is concerned with how particular areas of the outer part of the Earth have evolved. It attempts to account for all aspects of the rocks that can be mapped at and below the surface. The history of vertical and lateral movements, changes in climate, environments of deposition, rates and modes of erosion have to be interpreted from the great variety of observations, many of which are qualitative or descriptive. Magmatic, metamorphic, sedimentary and deformation processes have to be related in space and time to identifiable regional tectonic events that are often diachronous.

The elephant trap for writers of regional geology is to smother the reader in a snowstorm of detailed descriptions that fail to discriminate between the trivial and the vital. Readers thus afflicted, especially perhaps undergraduates, are led to associate regional geology with tedium. For this book, John Veevers has gathered together a team of writers who cover 575 million years of evolution of a region which represents a fortieth of the Earth's surface and a sixteenth of the continental lithosphere. Australia has no elephants and these authors eschew snow.

The apparent polar wander paths reveal that after some dalliance in the northern tropics during the early Palaeozoic, Australia has stayed in the Southern Hemisphere for most of the Phanerozoic. Records of oceanic palaeomagnetism for the last 160 Myr show how Australia's continental margins have been formed by a "can opener" type of rifting sequence which progressed from the north about 160 Myr anticlockwise around the margins to reach the Coral Sea about 60 Myr. These oceanic data do not reveal where or how these events began in what is now central New Guinea about 200 Myr. The origin of Australia's northern rifted margin before its late Cenozoic collision is not made explicit.

The evolving sequences of palaeoclimates and palaeoenvironments related to continental drift are dealt with deftly, the authors citing what they judge to be the three or four most sensitive and reliable diagnostic pieces of evidence for each Phanerozoic System of rocks, while a 25-page discussion of Australia's biogeography provides a glimpse of many unsolved problems and some of their seemingly more important implications. For example the tantalizingly uncertain data for Australian angiosperms leave us not sure whether some flowering plants were able to enter northern Australia from Asia during the early Cenozoic nor whether the flowering plants were able to migrate from northern Australia into Asia in the late Mesozoic and early Cenozoic.

The main part of the text presents Australia's structural evolution through the Phanerozoic by recognizing only three morphotectonic elements: the northern convergent margin, the huge area of platform and the various divergent (rifted) margins on the west, south and east. The stratigraphic evolution is dealt with by the convincing device of recognizing three stratigraphic regimes: the Portoroo (Late Cretaceous and Cenozoic), Innamincka (Mid Carboniferous to Mid Cretaceous) and the Uluru (Cambrian to Mid Carboniferous).

This is not an encyclopaedic account of Australia's Phanerozoic geology. The reader should not expect to turn to the book for detailed description of particular successions nor for a biostratigraphical discussion of the faunas and floras; the stratigraphy tends to be underlain by tectonic rather than biostratigraphic concepts. Sedimentological information is used throughout, but much of the text allows the fossils to sleep quietly (unmentioned) in their graves, so much so that some palaeontologists may turn in theirs. Perhaps that highlights the distance between stratigraphy and regional geology — a divorce not to be encouraged.

This book takes a refreshing approach to the synthesis of stratigraphy and tectonics, helped by writing which is concise without being over-condensed. Not only have Veevers and his colleagues produced an attractive and readable account of Australian geology, but more than in any other text I have seen succeed in conveying the excitement of regional geology. □

Michael Audley-Charles is Professor of Geology at University College London.

Chemists' enzymes

Richard Perham

Enzyme Chemistry: Impact and Applications.
Edited by Colin J. Suckling.
Chapman & Hall: 1984. Pp.255. £17.65, $36.
The Chemistry of Enzyme Action.
Edited by M. I. Page.
Elsevier: 1984. Pp.568. $66.50, Dfl. 179.

CHEMISTS have much to learn from, as well as contribute to, the study of enzyme catalysis. Although we no longer stand in awe at the catalytic power of enzymes, it is plain that there are still formidable problems to grapple with before we can claim a satisfactory understanding of their mechanisms. It is equally evident that we have not yet managed to apply all the lessons we have learned to, say, the industrial use of existing enzymes or the design of other catalysts.

Enzyme Chemistry is avowedly a didactic book, which sets out to document some of the past and to illuminate some of the future in the chemical study of enzymes and their products. As Kluger observes in an opening chapter which skilfully reviews the underlying physical organic chemistry of enzymes, if we were given the detailed three-dimensional structure of a protein of undisclosed catalytic specificity, it is unlikely that we could deduce the reaction catalysed. The goal of biomimetic chemistry — the design and construction of molecules that rival enzymes as catalysts — is thereby put in perspective. Shinkai concentrates on an encouraging approach to this goal that begins with a thorough study of the chemistry of coenzymes, whereas Colin Suckling addresses the question of selectivity in chemical and enzyme synthesis. The fastidious selectivity and exquisite stereochemical preferences of enzymes are, of course, now well known but — as Suckling gently reminds us — their use has sometimes been treated, a little scornfully, as unacceptable in the perfect total synthesis. He cites some splendid examples of a more robust attitude and of its beneficial effect on biomimetic chemistry.

Industrial chemists have never shunned an enzyme or even whole cells as a means to an end. This theme is taken up by Hesp and Willard in a lively and optimistic discussion of enzyme chemistry and drug design. A rational approach to chemotherapy has seemed just around the corner for almost 50 years, ever since the discovery of the biochemical basis of sulphonamide antibiotics. That prospect still tantalizes but one perceives a quickening of step as the new sophistication of enzyme and protein chemistry and of molecular modelling begins to impinge. Similar optimism is advanced by Cane in a neat chapter on the enzymes responsible for the biosynthesis of natural products. Those chemists who still resist the use of enzymes in total synthesis will be shocked to find his advocacy of the use of recombinant DNA techniques to facilitate a study of the enzymes involved. Bornyl pyrophosphate synthetase, an enzyme of monoterpene biosynthesis, has an estimated turnover number of 10 mol of substrate per mol of enzyme per hour. Cane flatters this enzyme (he is obviously but justifiably fond of the pathway) by referring to its catalytic power as extremely modest. Given that this may be typical of secondary metabolic enzymes, chemists would be foolish indeed to reject the help that molecular biology can offer them. They might even indulge in the delights of site-directed mutagenesis.

The book is completed by an article (Brown and Smith) on metal ions in biological systems—inorganic chemistry is not neglected—and an assessment by Keith Suckling of the effect of enzymological ideas on seemingly unrelated areas of biochemistry.

For a multi-authored book, the style and standard of presentation is unusually even. The authors communicate their affection for the subject and display a refreshing awareness of the benefits to chemistry that flow from enthusiastically embracing the study of enzymes, as well as the metabolites they convert. A significant criticism is that the references terminate in mid 1982 so that, for example, much of the current achievement of the molecular biological approach, let alone its potential, goes unrecorded. Biology is without doubt well placed to repay chemistry.

The Chemistry of Enzyme Action is part of the series entitled *New Comprehensive Biochemistry*. It is a large book (15 chapters) and includes most of the ground covered by *Enzyme Chemistry*, but goes well beyond it both in the range of topics and the depth in which they are treated. The principal aim of the book is to describe the physical and organic basis of enzyme action. Because the approach is mechanistic, the opening chapters concentrate on the energetics and substrate interactions of enzymes (Page, Kollman, Williams) and the use of kinetic (Engel, Douglas and Wilson) and isotope (Williams) methods in exploring mechanisms. Several systems are then selected for a detailed chemical scrutiny: enzyme reactions that utilize imine formation (Hupe), enzymes that require pyridoxal phosphate (Akhtar, Emery and Robinson), folate and biopterin cofactors (Benkovic and Lazarus), glycosyl transfer (Sinnott) and vitamin B_{12} (Brown). Biomimetic systems are represented in the concluding chapters on micelles and similar aggregates (Brunton), cyclodextrins (Komiyama and Bender) and crown ethers (Stoddart).

Despite its size, the book therefore remains selective in its coverage. The complementary part of this story, the participation of the enzyme protein and its structure in the enzymic reaction, is consciously left very much on one side. Thus, individual chapters will be read with profit by specialists but I fancy that the average undergraduate would find the rigour and detail too demanding. The logical place for such a book is the departmental library and the shelves of enzymologists with relevant interests. Typographical errors, while they do not abound, pop up from time to time, but the overall presentation is not unpleasing. All the authors can be congratulated on the comprehensive reference lists they have compiled. □

An independent view

John H. Lawton

The Ecological Web: More on the Distribution and Abundance of Animals.
By H.G. Andrewartha and L.C. Birch.
University of Chicago Press: 1985. Pp.506. $40.25, £33.25.

SCIENCE is most exciting when two alternative views of the world clash. The battle in population dynamics is between those who believe that density-dependent processes play a significant part in determining the distribution and abundance of animals, and those who do not. Andrewartha and Birch have led the density-independent school, ever since their book *The Distribution and Abundance of Animals* appeared in 1954. Their views have not changed significantly over the past 30 years, although the arguments have become more sophisticated and the controversy has recently enjoyed new vigour.

The central theme of *The Ecological Web* is a "theory of environment" based on "envirograms" — dendrograms whose branches trace pathways of influence impinging upon study-species. There are four directly acting components, resources, mates, malentities (that is, hazards) and predators, all of whose actions can be influenced by a cascade of steps in other parts of the envirogram. Andrewartha and Birch's views of population dynamics are therefore particular and detailed. They dismiss general, analytical models in two sentences: "We cannot see many testable hypotheses emerging from such abstract models.... So we say no more about them" (p.187). Approximately the first two-thirds of the book is devoted to describing and establishing their theory of environment; there follow in the final third several case-histories, on rabbits, two birds, marine fish (briefly), three species of insects and man. Only the spruce budworm, fish and man are not Australian examples.

I ought now to make my own position clear. Unlike Andrewartha and Birch, I find abstract general models of ecological processes useful, and I do think that density-dependent processes are largely irrelevant in understanding population dynamics. However I set out to read *The Ecological Web* with an open mind, but in the end found it lacking in many ways.

The theory of environment is largely verbal and pictorial, but is used to attack more formal, mathematical theory. The result is rather like comparing apples and oranges. The weakness of predominantly verbal arguments is best illustrated by an example. In the section "Competitive Coexistence and Displacement" the authors conclude, after reviewing several case-histories, that species can live together "because they are alike — not identical . . Conversely, when two species fail to coexist it is usually because they differ with respect to their success in professing a niche that they have in common". They seem not to notice that this conclusion is tautological; nor does it take us any nearer to a general understanding of competitive coexistence or exclusion.

Perhaps more seriously, Andrewartha and Birch often do not seem to understand many of the theories they either attack, or so lightly dismiss as futile. Moreover, they too often pass over evidence that contradicts their view of the world. Consider, for example, their efforts to explain population cycles in animals such as snowshoe hares or lemmings. They use neutrally stable Lotka-Volterra models (p.255) yet claim that "oscillations decline and finally disappear"; they do not. More interesting and realistic general models are ignored, as are efforts to test them[1,2]. Alternatively, take cases of "apparent competition" via shared enemies, or the role of spatial heterogeneity in population dynamics. They have much to say about both, but all their points are covered in more rigorous ways by existing general theoretical models. A small number of other examples will suffice to make my point. Great tit populations[3] are not limited by nest sites, as claimed. Population density does have important effects on the dynamics of tsetse flies[4], spruce budworms[5] and carabid beetles[6,7]. Sadly, I have to conclude that Andrewartha and Birch often develop their arguments by ignoring counter-evidence.

It appears that most of the confusion in this area of ecology centres on whether or not people are more impressed by population fluctuations, or by the fact that, despite such fluctuations, numbers of many species remain within comparatively narrow limits. Clearly not all populations are well regulated, but many are. It is important to know whether there are systematic patterns in the relative contributions of density-dependent and density-independent processes to the population dynamics of species from different taxa and habitats; but you will not find the answer to such questions in this book. Much has happened in population biology in the 30 years since the publication of *The Distribution and Abundance of Animals*. Because its treatment of these developments is so inadequate, *The Ecological Web* does little to advance the case for density independence. □

Classified material

V.H. Heywood

Guide to Standard Floras of the World.
By D.G. Frodin.
Cambridge University Press: 1985. Pp.619. £95, $175.

THE best description of this remarkable compendium is given by the subtitle, "An annotated, geographically arranged systematic bibliography of the principal floras, enumerations, checklists, and chorological atlases of different areas". The second part of the book, some 500 pages, comprises just that. There are, however, really two separate elements in this enterprise — a thoughtful analysis of *Floras* and floristics, and the application of this analysis to the geographically arranged guide to the most useful *Floras* and checklists of vascular plants of the world, selected according to the concept of "standard" works. The idea for this compilation dates back to 1962, and we are told that the main catalyst was the publication of the so-called "Green Book" produced by the *Flora Europaea* editorial committee for the guidance of contributors, in which a list of "standard" *Floras* of Europe was given.

Preparation of the *Guide* began in 1970 and was completed in 1975. It is a tribute to the author that he was able to contemplate such a work based in Papua New Guinea, scarcely one of the world's leading bibliographical centres (in a remarkable piece of understatement he comments that the "remoteness of Port Moresby was ... a handicap"!). Publication has been delayed for nearly six years after the submission of the manuscript to the publishers, and with a cut-off year of 1980 the text is already seriously out of date in many places.

Floristic projects are advancing so rapidly today that the whole question of maintaining an up-to-date database needs careful consideration. It is not at all clear to me that a hard-copy guide such as this, however selective it is, is the most effective instrument for bibliographical purposes. The author explains, however, that his aim was not just to present a classified bibliography but, by being analytical and interpretative, to act as a mirror on the progress of the subject. His ideas are expanded in the first section of the book. This includes essays on the style of *Floras* which are an important contribution to the literature on the subject. Frodin believes that the basic role of a *Flora* should still be a utilitarian and practical one — "inventory, identification and essential related data". He further echoes the increasingly expressed view that, for tropical countries in particular, floristic works should be written in such a way as to have a wide public appeal.

A disappointing feature of this introductory section is that although the author looks to the future, and emphasizes the need for a reappraisal of the ways in which floristic data are stored and presented, he does not put forward any very concrete suggestions. It is unfortunate that the book was completed just at the time when several new approaches to floristics were being implemented, most of them related to electronic data-handling. Thus a whole series of developments in the use of databases in systematics are omitted or only touched upon, such as the Vicieae database at Southampton, the revived Flora North America project (which will be heavily dependent on database technology) and the European Science Foundation Taxonomic Information System and database at Reading, not to mention the substantial reorganization of taxonomic services, involving electronic data processing, that several major taxonomic institutions are currently engaged upon.

In the main part of the *Guide*, Frodin's essays and annotations make interesting reading and present a very idiosyncratic interpretation of the facts reported. This material would have been better published separately. Indeed, altogether it is highly questionable whether it was wise for a world bibliography of *Floras* to have been undertaken as a one-man operation. One cannot but admire the author's enormous achievement in compiling this unique, expensive and fascinating work, but, at the same time, one cannot help feeling that the time for personal statements in this field has been bypassed by events, as Frodin himself hints. □

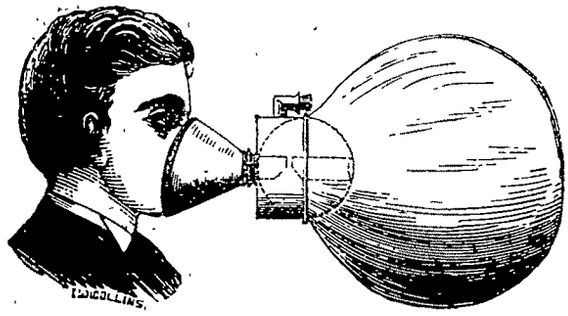
Late Quaternary Environments of the Soviet Union.
Edited by A.A. Velichko.
University of Minnesota Press/Longman: 1985. Pp.327. $45, £50.

This is a third, companion volume to *Late Quaternary Environments of the United States* (reviewed in *Nature* **311**, 488; 1984), and similarly arises from the USA–USSR bilateral agreement on the environment and meetings of the scientists sponsored by that agreement. This English language edition brings to the West a whole new range of data, new not least because much of the research summarized here is the product of recent years only.

As such, the book is self-evidently a publication of some significance. Given the vast area of the Soviet Union (exceeding that of the United States and Canada combined), and the diversity of the environments it encompasses, it is inevitable that the quality of coverage will be uneven. But slowly the long-standing, mostly geomorphologically based work is being supplemented by sedimentological, chronological and biostratigraphical studies. Appropriately enough, nearly all those Soviet scientists who have worked so hard to transform the situation figure in the book.

There are 30 chapters, many of which cover topics of international interest: the Late Pleistocene glaciation of the northern Soviet Union (in which a carefully argued case that large ice-sheets *did not* occupy the sites of the Barents and Kara Seas is prominent); mountain glaciation; permafrost in the Late Pleistocene and Holocene; and loesses, with a not unexpected demonstration, which nevertheless fills another gap in global correlation, that nine soil complexes are found above the Matuyma–Brunhes reversal in Central Asia. Furthermore, in the Tadzhik Depression the Olduvai reversal is identified; thus parallels emerge between Europe and points farther east, and ultimately with the global deep-sea isotope signal. An account of vegetational history gives a welcome insight into a greatly expanded field of endeavour, even though the data are regionally uneven and of varying quality, while a fascinating chapter on inland sea basins shows how sea-level change varies according to global as well as regional controls: thus 60,000 years ago the Caspian Sea rose to 76m above its present level, an event attributed to reduced evaporation and increased input from the Volga.



Palaeoclimatic reconstruction has long been a strength of Soviet scientists and included are convincing reconstructions of the principal stages along with inferences on their atmospheric circulation. It is shown that the "glacial monsoon" of the western Soviet Union, created by juxtaposition of cold high-pressure zones over the ice sheet and warmer low-pressure systems farther south, played a vital role in the transport and deposition of the loess deposits so critical for correlation.

Many readers will repair eagerly to the section on the dispersal of primitive cultures, not least in the hope that evidence from Siberia will throw light on the timing of the entry of man into the New World via the Bering Strait and on the attendant possible extinction of the megafauna. Unfortunately, however, the evidence from many late Palaeolithic sites in the Soviet Union is equivocal and contributes little to resolution of this problem.

The introduction to the English edition by H.E. Wright and C.W. Barnosky pulls the wide range of chapters together in an integrative and informative manner. Given the continuing exploration and development of the natural resources of the Soviet Union, it seems likely that much of the Late Quaternary framework evident there will be further elaborated and be of still greater benefit to Quaternary scientists elsewhere.

Under the Influence

DR. W.D.A. SMITH
Reader in Anaesthesia, University of Leeds
Honorary Consultant Anaesthetist,
Leeds General Infirmary

£12.00 208pp ISBN 0 333 31681 9

"This book presents an incomparable effort in presenting new material on the very foundations of anaesthesia, and is to be recommended wholeheartedly".

"The book jacket states unambiguously that 'Dr. W.D.A. Smith is the world authority on the history of nitrous oxide in anaesthesia'. If anyone might presume to doubt this, a reading of the book cannot fail to convince them of the truth of this statement".

P.W. Thompson
Anaesthesia

Over the past 15 years Dr. Smith has published a series of articles in the *'British Journal of Anaesthesia'* and related journals. These articles, containing a great deal of unique material, are brought together for the first time in this book. A useful preface provides an overview of the subject and contains new, previously unpublished material.

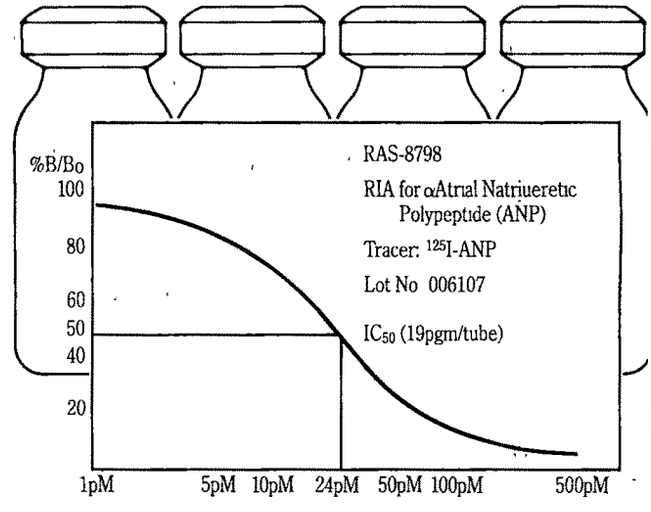
RADIOIMMUNOASSAY KIT FOR ALPHA-HUMAN ATRIAL NATRIURETIC POLYPEPTIDE

This kit is designed to measure specifically alpha-human atrial natriuretic polypeptide (alpha-hANP) and its related peptides by a competitive radioimmunoassay. It is intended for in vitro protocols only. The antiserum used for this assay was raised against synthetic alpha-hANP.



This kit contains sufficient reagents for 125 RIA tubes.

Catalog #RIK 8798

Sensitivity:
IC^{50} 19 pgm/tube

Specificity:

Peptide	% Cross-Reactivity
human αAtrial Natriuretic Polypeptide	100
rat ANP	100
ANP (8-33)	90
rat ANF (13-28)	50
rat Atriopeptin III	100
rat Atriopeptin II	27
ANP (18-28)	57
rat Atriopeptin I	3
Somatostatin	0
Oxytocin	0
Arg^8-Vasopressin	0

Contents:

- Triton X-100/water
- RIA buffer (powder)
- Standard alpha-hANP (lyophilized powder)
- Rabbit antiserum specific for alpha-hANP (lyophilized powder)
- ^{125}I alpha-hANP (lyophilized powder)
- Goat anti-rabbit IgG serum (lyophilized powder)
- Normal rabbit serum (lyophilized powder)
- Instructions/flow sheet for the RIA protocol
- Instructions for calculating the results and graph paper for plotting the results.

Peninsula Laboratories results show plasma levels of ANP-like immunoreactive material from rat plasma to be 444 +/− 160 pgm/ml +/− SD (N = 12)

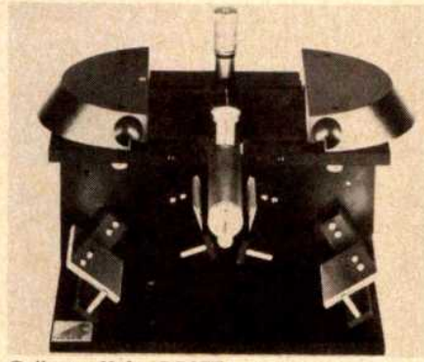
Eye movements recorded

This month's sampling of new products includes a sensitive system for recording human eye movements and a bench-top dry ice machine.

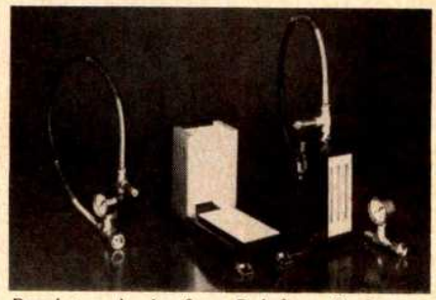
● Microtome manufacturers Temtool Ltd claim that a few years ago disposable 'razor' blades dominated the market, but now the economics of disposable versus re-usable knives is such that the re-usable knife is again competitive, especially when an automatic knife sharpener is used. The Rotosharp 2 from Temtool is an automatic sharpener that takes a wide variety of knife sizes and types (including tungsten carbide) and produces good edges in a few minutes.
Reader Service No. 100.



A 0.1-micrometre line pattern on silicon, written on a 0.35-micrometre-thick PMMA resist with the Philips Beamwriter.

● Sophisticated software, operating on a simple question-and-answer basis, has virtually eliminated manual adjustment of the Beamwriter EBPG-4 vector scan lithography system from Philips. Allowing linewidths down to 0.1 micrometres, the EBPG-4 offers true sub-micrometre resolution. Developed from the world's first commercial production-oriented vector scan electron beam pattern generator (EBPG) system, the EBPG-4 Beamwriter has been specially designed for direct writing onto silicon or gallium arsenide wafers but can also be used for making masks and reticles.
Reader Service No. 101.

● For applications in the laboratory where only the standard, 13A a.c. mains power supply is available, Lenton Thermal Designs Ltd has created a range of programmable bench-mounted furnaces: the Ultraspeed and the ECF series. The Ultraspeed reaches maximum operating temperature in only 10 min, and is available in two chamber sizes, 1.5 litres and 2.0 litres. ECF furnaces are available as a general purpose laboratory furnace and as an ashing furnace for the ashing of foods prior to microanalysis.
Reader Service No. 102.



These notes are based on information provided by the manufacturers. Use the reader service card bound inside the journal to obtain further information.

● Now available from Barnes Analytical/Spectra-Tech is the Collector II, an advanced version of their FTIR accessory for DRIFT (diffuse reflectance infrared Fourier transform) spectroscopy. A major development is the Blocker, a device which 'blocks' and greatly reduces or eliminates the specular reflectance component. The Collector II is especially suited for obtaining spectra from fibres, powders, foams, paint chips, catalysts (zeolites) and coal, as well as LC and HPLC eluents.
Reader Service No. 103.

Collector II for DRIFT spectroscopy.

● The SP8773XR absorbance detector, designed for routine operation at low detection limits, complements the Spectra-Physics line of modular, extended-range LC systems. LED display indicates real-time status, and provides self-diagnosis data for easy troubleshooting. Precision flow cells are readily interchanged to accommodate micro to preparative analyses.
Reader Service No. 104.

Bench-top dry ice from Polyfoam Packers.

● The Insta Ice Machine, available from Polyfoam Packers Corporation, is a portable bench-top dry ice machine weighing only six pounds. Blocks can be made in 1 lb or 2 lb sizes that do not require any further compacting. No electricity or batteries are needed — all that is required is a cylinder of liquid CO_2 with a syphon.
Reader Service No. 105.

Skalar's device for measuring eye movement.

● Precise recording of human eye movements is possible with a new system from Skalar of Holland. It involves a scleral induction coil, embedded in a flexible annulus of silicone rubber, which adheres tightly to the limbus of adult human eyes, concentric with the cornea, in a magnetic field. Two a.c. magnetic fields of similar frequency but in spatial and phase quadrature are created by field coils. An a.c. potential is induced in a sensor coil mounted on the eye and the magnitude and phase of the signal depend on the orientation of the eye in the field.
Reader Service No. 106.

● Anti-tubulin, useful for localizing microtubules in cells, quantitating the amount of tubulin in cells and tissue by radioimmunoassay and for gene cloning and studies of transformed cells, is available from Polysciences, Inc. The antibody can be used for immunocytochemical staining at dilutions of 1:50 to 1:100.
Reader Service No. 107.

Women in science and engineering

from Richard Pearson

One of the biggest changes in the employment scene in the second half of this century has been the rising participation of women in the labour market.

In the 1930s only one in ten women of working age in the United Kingdom were in employment, now nearly half are in or seeking employment; and women now account for 43 per cent of the labour force.

To date, however, women have been concentrated in the unskilled, lower-paid jobs, often working part-time hours. In terms of paper qualification, far fewer women are qualified than men. The 1981 *Census of Population* shows that while 7 per cent of adult men were graduates, the proportion of women so qualified was less than half this figure, at 3 per cent. However, the proportion of women gaining degrees has been rising fast towards equality, so that in 1983 42 per cent of those in higher education in 1983 were women compared with under 30 per cent twenty years earlier. Although more women are becoming qualified, the range of qualifications they are gaining is still markedly different from their male counterparts.

One of the most critical points for career choice is in the school system, where, by the age of 13, most girls have committed themselves to arts rather than science subjects, which severely constrains their later entry into science-based careers and courses in higher education. In terms of school qualifications, the proportion of girls gaining two or more A level qualifications in science, the usual minimum entry qualification for science or engineering courses in higher education, has barely changed, averaging about one in five.

Thus although the proportion of women going into higher education has risen dramatically over recent years, and they now account for more than half the intake into many medical schools, the changes on science and engineering courses have been far less marked. While in the case of engineering the proportion has more than doubled, women still account for only one in ten students, and the proportion of women on science courses has risen only slightly (Table 1). Of the women graduating last year, nearly two-thirds had art or social science degrees, only 21 per cent had science degrees and a mere 4 per cent had engineering degrees.

Table 1 Women first-year students as % of all students

Medicine	49.0
Engineering and technology	9.5
Science	33.1
Social science	44.4
Language, literature	69.0
Other arts	54.6
All subjects	40.7

Source: UCCA figures for 1982.

Curiously, girls' preferences within engineering do not seem to conform to the expected pattern in relation to individual subjects, thus women represent an above average 12 per cent of the total in chemical engineering, but under 6 per cent in electrical engineering and electronics, a field generally regarded as having a less traditional heavy engineering image. This rather lower representation may be because the competition for places is much harder in these subjects.

Table 2 Percentage of women in main graduate occupations.

Teachers	56.0%
Medics	29.6%
Scientists	16.0%
Accountants	8.1%
Lawyers	15.1%
Architects	4.2%
Engineers	1.2%

Source: *Census of Population*, for 1981.

In terms of jobs, the contrasts with men are even more marked. The most fundamental difference in 1981 was that almost a third of the women graduates (about 200,000) were not working or seeking work, mostly presumably for family reasons, while among men the corresponding figure was only 11 per cent. Interestingly, similar proportions of men and women graduates were unemployed — three per cent. Of the 450,000 working women, almost half were in teaching and indeed in this occupation they outnumbered their male counterparts. In medicine, women are relatively well represented, accounting for nearly one in three of all medical and dental practitioners. However, only about one in six of scientists are women, and fewer than one in eighty of the engineers (Table 2). There are far more graduate women in accountancy and in law than in engineering.

To remedy this low representation of women in science and engineering, for which both women and society generally suffer, the year 1984 was designated as WISE — Women in Science and Engineering — Year. Sponsored by the Engineering Council and the Equal Opportunities Commission, the main aim of the campaign was to educate and encourage girls, through a wide range of promotional activities, to take up careers in science and engineering. Even before WISE Year there have been initiatives aimed at encouraging schoolgirls to consider engineering careers. These have included special "Insight" programmes to allow sixth-formers to have close experience of engineering over a period of a weeks in industry, special scholarships and local school-industry liaison activities. The latter have not always been a success, however, with one girls' school returning a package of engineering careers leaflets with the comment "This must have been sent to us in error, this is a girls' school"

WISE Year included over 500 special conferences and events in schools, colleges and employers' premises, and many activities are continuing into 1985 and beyond. A limited number of new scholarships for girls was awarded during 1984 by the Engineering Training Board and others, but because the year was primarily aimed at raising awareness, it will be several years before any effective evaluation can be made, when any changes in subject choice among girls in schools and higher education will start to become apparent. At any rate, the organizers are already claiming that the year was a success.

An added urgency for women to enter technology-based courses was the fact that 1982 saw the number of 18-year-olds in the population, the traditional entry group into higher education, start to fall. The number will decrease from 1,000,000 to 650,000 in 1995 with most of the fall occurring during the latter part of the period. While the implications of this fall in terms of demand for higher education places have been hotly debated for several years now, in the cases of less popular subjects such as engineering, such a fall could have a significant effect on the numbers graduating. A rising relative demand by women will help mitigate against the overall fall and an increasing representation by women on engineering and technology courses may be the only means of ensuring an adequate future supply of graduates with key skills. Thus meeting the needs of the market and providing equality of opportunity could well become self-supporting policies in the late 1980s. □

UNIVERSITY OF THE WEST INDIES

St Augustine, Trinidad

DEPARTMENT OF ZOOLOGY

Applications are invited for a post of Senior Lecturer/Lecturer in the Department of Zoology, Faculty of Natural Sciences in the area of Entomology/Terrestial Ecology.

Salary Scales per annum: Senior Lecturer: TT$69,180 × 1,908 - 86,352 (Bar) × 1,908 - 90,168; Lecturer: TT$54,708 × 1,908 - 66,156 (Bar) × 1,908 - $77,604. FSSU. Unfurnished accommodation if available at 10% or furnished at 12½% or housing allowance of 20% of pensionable salary. Up to five full economy passages on appointment and on normal termination. Study and Travel Grant. Detailed application giving qualifications and experience and naming three referees to Campus Registrar, University of the West Indies, St Augustine, Trinidad, WI. Details of post sent to all applicants, but also available from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (W1829)A

UNIVERSITY COLLEGE CARDIFF

DEPARTMENT OF BIOCHEMISTRY

POST-GRADUATE RESEARCH ASSISTANT

Applications are invited for this post to work with Dr J Kay on the quantitation and localisation of the neutral proteinases involved in protein breakdown in normal and dystrophic human muscle. Duties to commence 1st October, 1985.

The appointment, financed by the Muscular Dystrophy Group of GB is for one year in the first instance, with a possible renewal for a second year. Salary range £6,600 - £7,055 per annum. Research expertise with radioimmunoassay/ELISA techniques would be an added advantage.

Applications, 2 copies, together with the names and addresses of two referees, should be forwarded to the Establishment Officer, University College, PO Box 78, Cardiff CF1 1XL. Closing date 23rd May, 1985. Ref: 2953. (6308)A

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF RADIATION ONCOLOGY, CLATTERBRIDGE HOSPITAL, BEBINGTON, WIRRAL.

TECHNICIAN GRADE 3

To operate a Fluorescence Activated Cell Sorter. Previous experience of this machine is not essential as full training will be given.

Applicants must possess ONC or equivalent in a biological discipline, or physics, plus three years laboratory experience. Applicants must also be able to demonstrate an aptitude for the use and understanding of complex laboratory equipment.

Salary within range £5,399 — £6,325 per annum.

This post is available for one year only.

Application forms may be obtained from the Registrar, the University, PO Box 147, Liverpool L69 3BX.

Quote Ref: RV/252/N. (6250)A

UNIVERSITY OF ABERDEEN

DEPARTMENT OF THERAPEUTICS AND CLINICAL PHARMACOLOGY

POSTDOCTORAL RESEARCH FELLOW

Applications are invited from suitably qualified candidates to work on a project using human hepatocyte cultures to relate drug metabolism to toxicity.

Applicants should have experience in drug metabolism and toxicology. Some experience in cell culture would also be an advantage.

The appointment, funded by the SHHD, is for one year in the first instance, with salary up to £9,390, depending on age and experience.

Applications, including curriculum vitae, and the names of two referees, should be forwarded to Dr G M Hawksworth, Department of Therapeutics and Clinical Pharmacology, University of Medical Buildings, Foresterhill, Aberdeen AB9 2ZD (closing date 23 May 1985), from whom further particulars may be obtained. (6256)A

Natural Product Chemist

Greenford, Middx

One of the main aims of our Microbial Biochemistry Department is the identification and purification of novel anti-microbial agents from natural sources.

A chemist is required to contribute to this aspect of the work, the major part of which is to develop rapid and novel techniques for the identification, extraction and purification of the active components of microbial broths and plant extracts.

Ideally, candidates should have a good degree and PhD in chemistry, preferably with a background in natural product chemistry and a knowledge of biological systems.

The Company offers excellent conditions of employment including a non-contributory pension scheme, bonus schemes, subsidised canteen and an active sports and social club.

Please send a full C.V or write for an application form to the Personnel Officer (REN), Glaxo Group Research Ltd., Greenford Road, Greenford, Middx UB6 0HE, quoting ref. U 565.

Glaxo ***Group Research Ltd***

ONCOGEN

- a Seattle based biotechnology firm conducting cancer research since 1983.
- affiliated with Bristol-Myers Company, Genetic Systems, and Syntex Corporations

RESEARCH FOCUS

- Monoclonal Antibodies for the diagnosis and treatment of human cancer
- Growth Factors and Growth Inhibitory Factors
- Hormones and their Receptors

OPPORTUNITIES

Ph.D's with expertise in:

- Monoclonal Antibodies
- Gene Cloning & Sequencing
- Eukaryotic Expression Systems
- Ligand-Receptor Interactions
- Assay Development

REWARDS

- Competitive salaries
- Attractive benefits
- Stimulating research environment
- Geographically desirable location

Please send resume to:

Sheryl J. Hackman

OVERSEAS LECTURESHIPS

CHEMISTRY

Applicants for the post should hold a Ph.D and have developed research interests at a post-doctoral level in Chemistry, preferably in the fields of polymer and or inorganic chemistry.

MICROBIOLOGY

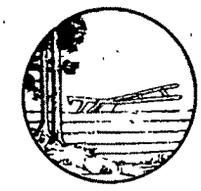
Applicants should be interested in conducting research into any aspect of Microbiology, although those with experience in Environmental Microbiology, Industrial Microbiology including fermentation technology, Microbal Metabolism and Virology are encouraged to apply.

In addition to pursuing your own research, you will participate in the teaching of undergraduate and post-graduate course in the Faculty of Science. Supervising research students will also be required.

Salary Scale: R16 257 — R 27 648 per annum.

Benefits ● annual bonus ● general leave ● medical aid ● pension ● travel, removal and settling-in allowances if eligible ● remission of fees.

The policy of the University is not to discriminate on the grounds of sex, race, colour or national origin.



For further information contact Mr G Henning, South African Universities Office, 278 High Holborn, London WC1V 7HE.

Closing date for applications 28th June 1985.

(W1832)

UNIVERSITY OF THE WITWATERSRAND

THE MACAULAY INSTITUTE FOR SOIL RESEARCH
DEPARTMENT OF PEAT AND FOREST SOILS

HIGHER SCIENTIFIC OFFICER

Applications are invited for appointment on a 3-year contract, on the Surface Water Acidification Programme (SWAP) under the auspices of The Royal Society, The Norwegian Academy of Science and Letters and the Royal Swedish Academy of Sciences.

A soil scientist/ecologist/forester is required to conduct research into the roles of vegetation and soils in modifying rainwater chemistry at three river catchments in Scotland as part of an integrated study of the effects of acid deposition on the acidification of surface waters and on the survival of fish and freshwater biota.

Candidates should possess a First or Upper Second Class honours degree in soil science, ecology, or foresty or a related subject, with at least two years' relevant post-graduate experience. Salary £7,435 — £10,039 per annum according to experience. Non-contributory superannuation scheme operative. The Macaulay Institute for Soil Research is an Equal Opportunities Employer.

Forms of application and further particulars may be obtained from The Secretary, The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen AB9 2QJ, to whom they should be returned by 20 May 1985.

Quote Ref. SWAP/1/85. (6285)A

Structural Geologist

Can you continue Scotland's tradition of excellence?

More than 100 years ago, pioneering research carried out in Scotland by Clough, Peach and Horne presented evidence that significantly altered the face of geological knowledge. Today, with the challenges of finding oil in the North Sea, Britoil offers you an opportunity to be part of a new era of geological exploration, charting courses that will lead well into the next century. As a major operator in the North Sea, Britoil is involved in more offshore blocks than any other company and is currently producing from nine fields.

We require a Structural Geologist to join our Glasgow-based Corporate Exploration Department who will work in basin modelling, basin evolution and spatial relations, interpretation of both deep and shallow seismic data, balancing 2D and 3D sections, fault geometry, reconstruction of basin development, studies on burial history, basin inversion, slope stability, and studies of fault seals and fractured reservoirs. You will be working with the most advanced technology, including remote sensing techniques. You will also be expected to run seminars and training courses for Geologists, Geophysicists and Engineers.

You will have considerable practical experience, be qualfied to PhD level, and will work with geophysical interpreters, seismic stratigraphers, exploration and production geologists, and computer experts. You will be an expert in the latest structural geology concepts, particularly in relation to extensional tectonics, continental margins and deep seated structural behaviour. You will also have some knowledge of compressional tectonics, thrusting and shear mechanics. Preferably, your experience will not be limited to hard rock or superficial sediment deformation but will include a broad knowledge of sedimentary rock deformation.

Your salary and benefits package will reflect the importance of your input to the company's future performance. In addition to profit sharing, BUPA, and a company car, you will have generous assistance with relocation, where appropriate.

To apply, write giving details of your qualifications and experience and quoting reference SG/HK/N to: Howard Kewney, Senior Personnel Officer, Britoil plc, 150 St Vincent Street, Glasgow G2 5LJ.

The **LEPETIT RESEARCH CENTRE** is one of the four International Research Centres of the Merrell-Dow Research Institute of MERREL-DOW-PHARMACEUTICALS. We are devoted to discovery, characterisation and development of innovative drugs in the anti-infective field we are the discoverers of the rifamycin family of antibiotics We have also discovered and are presently developing a novel anti-straphylococcal agent

We are looking for:

★ MEDICINAL CHEMIST

For semisynthetic modification of antibiotic molecules derived from fermentation

★ NATURAL PRODUCT CHEMIST

To extract, purify, characterise and help with structural elucidation of novel fermentation molecules with antibacterial activity

For both positions we request:

- Ph.D. in Chemistry with a minimum of two years postdoctoral experience.
- Relevant Publications/Patents.

★ GROUP LEADER, MICROBIOLOGY

The successful candidate will be responsible for supervising a team of scientists dedicated to the discovery of novel and innovative anti-infective drugs. Previous industrial experience is an advantage but not an absolute prerequisite. Age guide: 33-37.

He/she will have.

- 5-10 years experience, supported by substantial publication record in one or the following fields· Microbial Physiology or Genetics or Biochemistry or Immunology.
- Ability to motivate a diverse group of scientists.
- Motivation to apply a first-grade knowledge of basic science to discovery and characterization of molecules to become medical/commercial successes

For all positions, knowledge of English in the verbal and written form is essential Knowledge of Italian is not necessary

The Lepetit Research Centre is soon to the relocated in newly built modern facilities 30 Km North of Milan (Italy).

Applications, indicating position wanted, including C.V. and list of publications, should be sent to·

Director R & D (Selection)
Lepetit Research Centre
Via Durando 38, 20158 MILAN (Italy)

UNIVERSITÉ DE MONTRÉAL
Faculté des arts et des sciences
Département de sciences biologiques

POSTE DE PROFESSEUR ADJOINT

Le Département de sciences biologiques de l 'Université de Montréal est à la recherche d'un professeur en biologie du développement animal.
Fonctions
Enseignement au premier cycle embryologie générale at anatomie microscopique (avec travaux pratiques), aux 2e et 3e cycles: cours avancés dans la spécialité du candidat; recherche en biologie du développement animal
Exigences
Ph D. ou D.Sc Une expérience pertinente en développement du système nerveux pourrait être un atout.
Traitment
Selon les normes de la convention collective en viguer.
Date d'entrée on fonction
Le ler septembre 1985.
Date de clôture des candidatures
Le ler août 1985.
Les candidates sont priés de faire parvenir leur leur curriculum vitae, une copie de leurs diplômes et trois lettres de recommandation à:
M Roch Carbonneau, Directeur, Départment de sciences biologiques, Universite de Montréal, C.P 6128, succursale A, Montréal (Québec) H3C 3J7
Conformément aux exigences prescrites en matière d'immigration au Canada, cette annonce s'adresse aux citoyens et aux résidents permanents au Canada. (NW1720)A

The Department of Cell Biology at Baylor College of Medicine currently has two faculty positions open for outstanding scientists, at either a junior or senior level, in the area of contemporary molecular genetics We are particularly interested in candidates that are involved in applying techniques of recombinant DNA research for studying basic problems in cell and development biology. The present well-funded and nationally renowned faculty in this Department reflects a diverse set of research interests, and the existing resources should be an attractive feature for prospective candidates

Send curriculum vitae with names of three references to:

Dr. Jeffrey M. Rosen,
Professor, Depart. of Cell Biology,
Baylor College of Medicine,
1 Baylor Plaza,
Houston, Texas 77030 (NW1623)A

Faculty Position — Biochemistry

The Department of Biochemistry, University of Virginia School of Medicine invites applications for a tenure-track, full-time faculty position at the assistant or associate professor level starting no later than 1 September 1986.

Applicants must exhibit a strong commitment to teaching and to establishing a vigorous, independent research program. The candidate must have a doctoral degree in Biochemistry or a closely related field with postdoctoral experience; however, applications are encouarged from all outstanding candidates irrespective of their current interests.

Please submit letter of application, curriculum vitae, and three reference letters to: Dr. Ching-hsien Huang, Chairman of Search Committee, Department of Biochemistry, Box 440, University of Virginia School of Medicine, Charlottesville, Virginia 22908. Application deadline is 1 August 1985. *An Equal Opportunity/ Affirmative Action Employer* (NW1704)A

THE UNIVERSITY OF TEXAS AT AUSTIN U.S.A.

POSTDOCTORAL ASSOCIATE IN PLANT AND MICROBIAL MOLECULAR GENETICS

A 12-month appointment is available beginning June 1985, with possibility of renewal. Salary commensurate with experience Preference given to applicants with expenence in microbiology, trans poson mutagenesis, Ti-vectors, and recombinant DNA technology Major research emphasis on microbial cellulose gene structure and expression, but other research on the molecular genetics of cellulose gene expression in higher plants and algae will be undertaken Well equipped new laboratory and excellent opportunity to interact with a versatile research team in an internationally recognized Botany Department.

Please send résumé, brief summary of research experience, and list of three referees to Dr. R Malcolm Brown, Jr., Department of Botany, The University of Texas at Austin, Austin, TX 78713-7640, U S A. Telephone (512) 471-3363. (NW1715)A

UNIVERSITY OF VERMONT COLLEGE OF MEDICINE

DEPARTMENT OF MEDICINE

RESEARCH ASSISTANT PROFESSOR

Full time research faculty to conduct independent and collaborative research in fields relating to hemostasis and thrombosis using cultured vascular cells Areas of expertise can include biochemistry, microbiology, cell biology, or cell physiology

Applicants must have a Ph D degree with demonstrated proficiency in growing vascular endothelial cells in culture A research grant/career award providing 50% of annual salary desirable but not essential.

Qualified and interested candidates should send CV, names and addresses of 3 references and brief outline of research interests by June 15 to. John C. Hoak, M.D., Department of Medicine, Fletcher House 311, MCHV, Burlington, Vermont 05401.

An Affirmative Action Employer. Women and minorities encouraged to apply (NW1716)A

DIRECTOR

BIOTECHNOLOGY RESEARCH INSTITUTE MONTREAL

The Organization

The National Research Council of Canada is establishing a new Biotechnology Research Institute in Montreal. This new research institute emphasizes the industrial applications of biological sciences and focuses on the development of new processes and products. It fosters generic research and technology transfer to industry and promotes communication and collaboration amongst industrial, university, federal and provincial government laboratories.

The Research Areas

The main areas of research include:

- Fermentation and biochemical and process engineering
- Genetic engineering
- Cell fusion and molecular immunology
- Enzyme technology and protein engineering

A major large scale fermentation facility will allow pilot scale experimentation with new fermentation methods and economic evaluation. The R & D will focus on agrofood, energy treatment and chemicals, pharmaceuticals, waste product and forestry.

The Position

The Director reports to the Vice-President (Biotechnology and Chemistry) and is an active contributor to the National Biotechnology Program. The Director is responsible for planning, organizing, implementing and controlling the Institute's research and development programs and advises senior management on long term research goals. The Director is also responsible for establishing close ties with universities and industries and undertaking research projects on a cooperative basis.

The Candidate

The person appointed will have an established reputation for outstanding leadership in research and development and the ability to lead, manage and coordinate the activities of the Institute. Candidates will have many years of research experience in a biotechnology related discipline and demonstrated ability in research managment. Knowledge of both the English and French languages is essential.

The Institute

The Biotechnology Research Institute is located in downtown Montreal in a new $60 million, 18,000$m^2$ complex. It will employ 220 people and will host up to 80 researchers from industries, universities and other research organizations. It will have an annual budget of $35 million.

BENEFITS are fully competitive and SALARY will be commensurate with qualifications and experience.

PLEASE SEND A DETAILED RÉSUMÉ IN CONFIDENCE TO THE:
General Manager,
Personnel Branch,
National Research Council of Canada,
Ottawa, CANADA, K1A 0R6.

(NW1706)

National Research Council Canada | Conseil national de recherches Canada

MOLECULAR BIOLOGY DEPARTMENT

Post Doctoral Scientists

Salary from £9,000

Celltech, a leader in the field of biotechnology, has achieved its present success in the space of four years. Pioneers in several areas, our achievements are based on the foundations of scientific excellence, innovation and commercial expertise

Due to continuing expansion, the Molecular Biology Department requires further Post Doctoral Scientists or graduates about to submit a PhD thesis to join teams cloning and sequencing genes of potential therapeutic importance Experience with the isolation of proteins and/or cloning techniques would be an advantage.

Celltech is an ambitious and forward looking company, which places as much emphasis on its people as its products. You will work in a small friendly team, gaining invaluable broad-based experience, with plenty of opportunity for advancement. Please send a detailed c.v to Jane Walley, Celltech Ltd., 244-250 Bath Road, Slough, Berks SL1 4DY, quoting Ref. 258

CELLTECH

READVERTISEMENT

THE ANIMAL VIRUS RESEARCH INSTITUTE

HEAD OF IMMUNOLOGY AND PATHOLOGY

Applications are invited for a new post of Head of the Division of Immunology and Pathology, the appointment to commence as soon as possible.

Candidates should have a high academic research record in molecular or cellular immunology, with experience, or an interest in, the immunology of virus infection in farm animals, and proven skills of leadership

The Division includes Departments of Immunology, Experimental pathology and Vaccine Research.

Salary in scale £16,229 — £21,834 Grade 6 (pay award pending). Sick leave and non contributory superannuation schemes. 25 days annual holiday. House may be available for suitable married applicant. The successful candidate may qualify for financial assistance with removal expenses.

HIGHER SCIENTIFIC OFFICER

Applications are invited for the post of Higher Scientific Officer Band 1 to work in the Division of Molecular Biology, Department of Biochemistry. The appointment to commence as soon as possible. The successful candidate will assist with work on the structure and function of the blue tongue virus genome

Candidates should have at least 3 years post graduate research experience. Degree in Biochemistry or Microbiology and a PhD

Salary scale £7,435 — £10,039 (pay award pending), sick leave and non-contributory superannuation schemes, 22 days annual holiday. House may be available for suitable married applicant.

For both posts applicants should send a curriculum vitae and the names of two referees by 31 May 1985 to the Secretary, The Animal Virus Research Institute, Ash Road, Pirbright, Woking, Surrey GU24 0NF, from whom further particulars may be obtained. The Animal Virus Research Institute is an Equal Opportunities Employer. (6216)A

INSTITUTE OF CANCER RESEARCH

TECHNICIAN/RESEARCH OFFICER

Required for CRC/MRC funded post at the Institute's laboratories at Sutton, Surrey, to work on clonal analysis of formal and neoplastic tissue in mouse aggregation chimaeras The mosaic markers currently used include H2 antigens and lectin polymorphism demonstrated immunocytochemically in tissue sections (cf J Embryol exp Morphol, 76, 83-93; Nature 313, 689-691; Cell, 40, 425-429).

Applicants should have expertise in immunocytochemistry, including cryostat sections. Additional experience in the following would be an advantage: making chimaeras, preparing antibody-enzyme conjugates, microdissection, general animal handling. The post is available now; an early starting date would be ideal so as to provide an overlap to learn techniques from the present incumbent, who is expected to leave during the summer. Salary in scale £5,738 - £8,492 pa, plus London Allowance of £623 pa.

Further details may be obtained from Dr Bruce Ponder, Institute of Cancer Research, Haddow Laboratories, Clifton Avenue, Sutton, Surrey SM2 5PX, telephone 01-643 8901, ext 293. Applications in duplicate should be sent to the Personnel Officer, Institute of Cancer Research, 17A Onslow Gardens, London SW7 3AL, quoting ref. 301/B/83. Closing date for applications 17th May, 1985. (6264)A

INSTITUTE OF CANCER RESEARCH

TEAM LEADER

Applications are invited for a 5-yea appointment with career prospects t lead a research team in the Institute' Cell and Molecular Biology Sectio in the Chester Beatty Laboratories Fulham Road, London, SW3. Estab lished groups in the Section ar working on Oncogenes, Chromatin Structure and Function, Develop ment Genetics, Cloning Technolog and Human Retroviruses. The Insti tute is jointly funded by the Cance Research Campaign and the Medica Research Council on a system of si year grants which are reviewed ever fourth year.

Candidates should be experience in any field of research related to th molecular biology of cancer bu applications from those working or the structure and function of trans forming proteins are especiall sought.

The salary, depending on quali fications and experience will be in th range £10,330 — £14,925 pa, plu London Allowance of £1,233 pa

Applications consisting of a CV an outline research proposal, and th names of three referees should b sent, in duplicate, to the Personne Officer, Institute of Cance Research, 17A Onslow Gardens London, SW7 3AL, quoting re 300/G/12.

Applicants are advised that in th majority of the Institute's premise smoking is prohibited. (6274)A

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF PATHOLOGY

UNIVERSITY LECTURER OR UNIVERSITY DEMONSTRATOR IN VIROLOGY

Applications are invited for a post of either a University Lecturer or a University Demonstrator (the equivalent of University Assistant Lecturer) in the Department of Pathology, appointment to commence on 1 October 1985 or as soon thereafter as possible.

Candidates should hold a PhD degree or equivalent and have several years post-doctoral experience in a relevant area. The successful candidate will join the Division of Virology in the Department of Pathology and will be expected to contribute to both teaching and research in Virology.

Further information about the duties and conditions of appointment may be obtained from the Secretary of the Appointments Committee for the Faculty of Biology 'B', 19 Trumpington Street, Cambridge, CB2 1QA, to whom applications (10 copies) including a curriculum vitae, list of publications and the names of not more than three referees, should be sent so as to reach him not later than 1 June 1985. BRISTOL POLYTECHNIC

SCIENCE DEPARTMENT

LECTURER II/ SENIOR LECTURER IN CLINICAL CHEMISTRY/ BIOCHEMISTRY REF NO L/12

Applications are invited from graduates in a relevant subject an preferably FIMLS who have researcl and/or hospital laboratory experienc in clinical chemistry A particular in terest in the development of new assa methods is desirable.

The successful applicant will teacl clinical chemistry and biochemistry o Degree, BTEC and FIMLS course and will be expected to initiate a active research programme.

The appointment will commence o 1 September 1985. Salary scale; LI £7,548 — £11,175 (bar) — £12,099 pe annum; SL £11,175 — £13,128 (bar — £14,061 per annum.

The appointment will be made o the appropriate scale according t relevant previous service/experience (Progression from the LII scale to th SL scale in in accordance with the pro visions of the Burnham Further Edu cation Report).

For further details and an appli cation form, to be returned by 1 May, 1985, please contact the Per sonnel Office, Bristol Polytechnic Coldharbour Lane, Frenchay, Bristo or ring Bristol 656261 ext 216 or 217 (6247)A

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF MICROBIOLOGY

JUNIOR RESEARCH ASSOCIATE (FERMENTATION TECHNOLOGY), POSTDOCTORAL RESEARCH ASSOCIATE, JUNIOR RESEARCH ASSOCIATE

The following posts, financed by a grant from Tyne and Wear County Council, within the Microbial Technology Group, are available for two years for the promotion of the industrial exploitation of the Group's research activities.

JUNIOR RESEARCH ASSOCIATE (FERMENTATION TECHNOLOGY)

To take charge of the day to day operations of the Fermentation Unit and to provide support for collaborative projects with local industry. Applicants should have a good honours degree in an appropriate biological subject and experience in fermentation and/or appropriate industrial or research experience in running fermenters. Commencing salary up to £7,520 per annum on the National Range IB salary scale (£6,600 - £8,920 per annum).

POSTDOCTORAL RESEARCH ASSOCIATE

To work on the development of new techniques for the isolation and screening of novel microorganisms for new bioactive compounds. Applicants should have experience in Microbiology or a related biological discipline and preference will be given to those familiar with analytical techniques used in chemosystematics and with computer assisted data handling methods. Commencing salary up to £7,980 per annum on the National Range IA salary scale (£7,520 - £12,150 per annum).

JUNIOR RESEARCH ASSOCIATE

To work with the postdoctoral Research Associate on the isolation of novel microorganisms. Applicants should hold a good honours degree in a biological subject. Commencing salary £6,600 per annum on the National Range IB salary scale (£6,600 - £8,920 per annum).

JUNIOR RESEARCH ASSOCIATE

To work with the postdoctoral Research Associate on the isolation of novel microorganisms. Applicants should hold a good honours degree in a biological subject. Commencing salary £6,600 per annum on the National Range IB salary scale (£6,600 - £8,920 per annum).

Written applications, providing full curriculum vitae and names and addresses of three referees should be submitted to Professor A R Archibald, Microbial Technology Group, Department of Microbiology, Medical School, Framlington Place, Newcastle upon Tyne, NE2 4HH. Tel 0632 328511 Ext 3710 not later than 23rd May 1985.

(6302)A

UNIVERSITY OF LONDON INSTITUTE OF PSYCHIATRY

DEPARTMENT OF NEUROPATHOLOGY

"NEW BLOOD" LECTURESHIP IN NEUROIMMUNOLOGY

Applications are invited for a "New Blood" lectureship in Neuroimmunology in the Department Of Neuropathology from 1 October 1985. Applicants should have research interests in the development of antibodies as cell-specific markers to be used for the identification of various types of cells in the brain. The successful candidate will be expected to follow progress in immunology relevant to Neurological and mental illness to assist in the development of the clinical application of recent discoveries and to teach neuroimmunology to postgraduate psychiatrists and neuroscientists.

Salary according to age, qualifications and experience either on the Lecturer scale (£7,520 — £14,925 plus £1,233 London Allowance) or the Clinical Lecturer scale (£10,130 — £17,560 plus £807 London Allowance).

Further information can be obtained from Professor P L Lantos and application forms are available from Miss M E Harries, Department of Neuropathology. Tel 01-703 5411 Ext 338.

Applications with a full curriculum vitae should be returned to the Secretary, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF by 12 May 1985.

(6268)A

UNIVERSITY OF LEICESTER

DEPARTMENT OF ASTRONOMY

ACCRETION PROCESSES ON COMPACT OBJECTS

An SERC-supported postdoctoral position in the above research area will be available from October 1985. Present work in this area in the Astronomy Department includes theoretical studies of accretion processes in cataclysmic variables and X-ray binaries, and interpretation of EXOSAT and other results on these systems obtained on collaboration with members of the X-ray Astronomy Group. Applications are invited from both theoretical astrophysicists with backgrounds in relevant subjects (e.g. astrophysical fluid mechanics, solar/stellar physics, or accretion processes in other contexts) and from astrophysicists experienced in the interpretation of data from related systems.

The post is tenable for up to three years, at a starting salary (under review) up to £9,390 plus USS benefits, depending on qualifications and age. Further information can be obtained from Dr A R King, Astronomy Department, University of Leicester, Leicester, LE1 7RH. Applications, including a curriculum vitae and list of publications, must be received by 15 June, 1985, and applicants should themselves request two referees to write to Dr King by the same date.

(6291)A

CSIRO AUSTRALIA

RESEARCH FELLOW

$A25,342 — $A37,274

DIVISION OF MOLECULAR BIOLOGY SYDNEY NSW

FIELD: Molecular Biology/Genetic Engineering.

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes. Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Molecular Biology is a member of the Institute of Animal and Food Sciences

GENERAL: The Division of Molecular Biology conducts scientific research in molecular genetics and cell biology It has a staff of approximately 100 Programs are divided into Animal Cell Growth and Development, DNA Maintenance and Modification, and Gene Technology. It is situated in Sydney, at North Ryde, close to Macquarie University and major biotechnology companies.

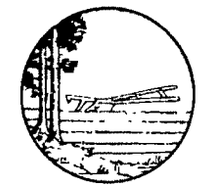
DUTIES: The appointee will be located in the Gene Technology program, and will undertake collaborative research in isolation, analysis and expression of genes coding for vaccine antigens, and the development of novel systems for their delivery in vivo. The broader activities of this program include research into the regulation of gene expression in animal, fungal and procaryotic systems.

QUALIFICATIONS: A PhD degree or equivalent qualifications in molecular genetics, biochemistry or related discipline, preferably with relevant post-doctoral training. Experience in recombinant DNA research is essential. Experience in molecular techniques of protein and immunological analysis would be an advantage.

TENURE: A term of 3 years with Australian Government superannuation benefits available.

APPLICATIONS: Stating relevant personal particulars, including details of qualifications and experience, the names of at least two professional referees and quoting reference No. A3475, should be directed to:

Dr G.W. Grigg
Chief
CSIRO Division of Molecular Biology
PO Box 184
NORTH RYDE NSW
AUSTRALIA 2113



by four weeks from date of application.

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER

(W1828)A

MACAULAY INSTITUTE FOR SOIL RESEARCH

DEPARTMENT OF MINERAL SOILS

HIGHER SCIENTIFIC OFFICER

Applications are invited for appointment on a 3-year contract, on the Surface Water Acidification Programme (SWAP) under the auspices of The Royal Society, The Norwegian Academy of Science and Letters and the Royal Swedish Academy of Sciences.

A physical chemist/geochemist/soil chemist is required to conduct research into the chemisry of soil/water interactions at three river catchments in Scotland as part of an integrated study of the effects of acid deposition on the acidification of surface waters and on the survival of fish and freshwater biota

Candidates should possess a First or Upper Second Class honours degree in chemistry, geochemistry, or soil science with at least two years' relevant post-graduate experience. Salary £7,435 — £10,039 per annum according to experience Non-contributory superannuation scheme operative. The Macaulay Institute for Soil Research is an Equal Opportunities Employer.

Forms of application and further particulars may be obtained from The Secretary, The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen AB9 2QJ, to whom they should be returned by 20 May 1985.
Quote Ref. SWAP/3/85.

Birchwood Science Park
Warrington, Cheshire Tel. 0925-825650

(6249)A

POSTDOCTORAL TRAINING PROGRAM IN SLOW INFECTIONS

NIH/UCSF Postdoctoral training program in the molecular biology and chemical structure of slow infectious agents, or prions. Program emphasizes studies on experimental scrapie in rodents as a model degenerative neurologic desease Areas of study include: molecular cloning, expression of cloned genes, gene mapping and time structure, immunogenetics, production of monoclonal antibodies to synthetic peptides, ultrastructure and x-ray diffraction of filamentous and membrane proteins, molecular neuropathology and experimental neurology Program is directed by five UCSF faculty members. Candidates should be U.S. citizens or permanent residents committed to a research career and hold a Ph.D., M D. or D.V M. degreé. Experience in molecular biology, biochemistry, biophysics, macromolecular structure, immunology, virology, neurology or neuropathology is encouraged. Appointments, beginning June 1, 1985, are for 3 years with a salary ranging from $15,996 to $30,000.

Send curriculum vitae and 3 letters of reference to Dr. Stanley Prusiner, Department of Neurology, HSE 781, University of California, San Francisco, CA 94143.

The University of California is an affirmative action equal opportunity employer. (NW1710)A

POSITION AVAILABLE AT THE UNIVERSITY OF CALIFORNIA, DAVIS IN HUMAN DEVELOPMENT

12-month (including one month vacation), 70% teaching/30% research, tenure-track position at the Assistant Professor level, beginning January 1, 1986 (negotiable). Salary range. $29,600-$33,600 (range adjustment expected 7/1/85). Applicants must hold a Ph D in relevant discipline with a specialization in human behavioral development. Emphasis in biological bases of behavior or behavioral genetics is highly desirable. Must have demonstrated research expertise in adolescent/adult development. Responsibilities will include teaching and advising in Child/Human Development at the undergraduate and graduate levels.

A vita, a statement of qualifications, list of publications, transcripts of undergraduate and graduate work if within 5 years of receiving doctorate, and names and addresses of at least three references should be sent to: R. H. Kraft, Chair, Human Development Search Committee, Department of Applied Behavioral Sciences, U.C. Davis 95616. Final filing date: To be assured of consideration applicants should submit materials by July 31, 1985.

The University of California is an Affirmative Action/Equal Opportunity Employer. (NW1638)A

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF PHARMACOLOGY

UNIVERSITY LECTURER OR UNIVERSITY DEMONSTRATOR IN IMMUNOPHARMACOLOGY
New Blood

Applications are invited for a post of either a University Lecturer or a University Demonstrator (the equivalent of University Assistant Lecturer) in the Department of Pharmacology, appointment to commence on 1 October 1985 or as soon thereafter as possible.

The person appointed will be expected to develop a research programme in immunopharmacology and be involved in undergraduate teaching.

Applicants should have a PhD degree or equivalent and research experience in cellular or molecular immunology.

Further information about the duties and conditions of appointment may be obtained from the Secretary of the Appointments Committee for the Faculty of Biology 'B', 19 Trumpington Street, Cambridge CB2 1QA, to whom applications (10 copies) including a curriculum vitae, list of publications and the names of not more than three referees, should be sent so as to reach him not later than 1 June 1985. (6262)A

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF GENETICS

Applications are invited for two posts:

UNIVERSITY LECTURESHIP OR DEMONSTRATORSHIP

(equivalent to UAL) in the field of Molecular Plant Genetics under the new Blood Scheme. The person appointed will be expected to establish a research programme and to undertake teaching.

UNIVERSITY DEMONSTRATORSHIP

preferably in the field of microbial genetics (either bacteria or yeast) though well qualified candidates from other areas of genetics will also be considered.

Relevant pensionable scales of stipends are as follows: UL £10,330 a year rising by eleven annual increments to £15,930. UD £7,980 a year rising by four annual increments to £9,860. Informal enquiries concerning either of these posts can be made to Professor J R S Fincham, Department of Genetics, Downing Street, Cambridge CB2 3EH.

Further particulars may be obtained from Secretary to the Appointments Committee, Faculty of Biology A, Zoology Department, Downing Street, Cambridge CB2 3EJ to whom application (3 copies) including curriculum vitae and names of three referees should be sent to reach him by 31st May 1985.

Applications for new blood post should be marked 'NBGEN'. (6276)A

UNIVERSITY OF DURHAM

POSTS IN ELECTRONICS/ ELECTRONIC ENGINEERING

Applications are invited for the following posts in a new School of Engineering and Applied Science being formed in Durham to consolidate expansion of existing electronics research and teaching in the University.

CHAIR OF ELECTRONICS

Applicants should have a wide range of interests in digital and analogue electronic circuits and systems. It is expected that the person appointed will have an established reputation for research combined with recent experience in industry or close collaboration with industry.

THREE LECTURESHIPS

The University has created three new Lectureships in Electronics/ Electronic Engineering. Candidates should preferably have experience in digital or analogue circuit or system design and their applications in communications, signal processing, or information engineering. Preference will be given to candidates who have recent experience in industry or have collaborated with industry in a research programme.

Salaries on the scales (under review) - Professors, basic, £18,172 -£21,156; Lecturers £7,520 - £14,925 with the usual pension arrangements.

Applications (chair - 12 copies; Lectureships - 3 copies) naming three referees by 31 May 1985 to the Registrar, Science Laboratories, South Road, Durham, DH1 3LE, from whom further particulars may be obtained. (6301)A

UNIVERSITY OF BRISTOL

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH BIOCHEMIST
(Scale 1A)

Applications are invited for the above position to pursue research into the mechanism of action of insulin. The post is funded under an MRC Programme Grant (to Dr R M Denton) and will be available from 1 July 1985 until 30 September 1988 in the first instance, with a starting salary in the range £7,520 — £9,860 (under review).

Studies will be largely concerned with exploring the mechanisms involved in the effects of insulin on the activity of pyruvate dehydrogenase and other enzymes in mammalian cells (especially fat cells).

Applicants with appropriate experience, for example in the study of reversible phosphorylation of proteins or mitochondrial metabolism should send a complete Curriculum Vitae, plus the names of two or three referees to Dr R M Denton, Department of Biochemistry, University of Bristol Medical School, University Walk, Bristol BS8 1TD (0272-24161 ext 798), from whom further information can be obtained.

Closing Date: 30 May 1985. (6289)A

THE ROWETT RESEARCH INSTITUTE
Bucksburn, Aberdeen, AB2 9SB

DEPARTMENT OF MICROBIAL BIOCHEMISTRY

MOLECULAR BIOLOGIST

Applications are invited for a new 3-year post in the Department of Microbial Biochemistry to investigate gene manipultion in the exploitation and study of fungal cellulases.

The appointee would be expected to collaborate with other biochemists, molecular biologists and physical chemists at the Rowett Institute and elsewhere to obtain basic information on the structure/function relationships of cellulase components. The long term objective would be to obtain, by site specific mutagenesis, cellulases with new properties which would attract commercial interest.

Applicants should possess a first or second class honours degree in biochemistry or microbiology with a PhD and relevant experience in molecular biology.

Salary will be in the grades of SSO/HSO — £9,329 to £12,050 and £7,435 to £10,039 pa respectively (pay award pending). The Institute operates a non-contributory Superannuation Scheme although 1½% is contributed for dependent relatives. The Institute is an Equal Opportunities Employer.

Letters of application accompanied by a CV and the names and addresses of two referees should be sent to the Secretary at the above address by 23 May 1985 (6267)A

CRYSTALLOGRAPHY GROUP
UNIVERSITY CHEMICAL LABORATORY
Cambridge, UK

POST-DOCTORAL CRYSTALLOGRAPHER

Post-doctoral crystallographer wanted to join a group of chemists and crystallographers working on the structure of DNA fragments and DNA-drug complexes

The group have well developed techniques for synthesis and crystallisation, are currently working on four different structures with base pair mismatches and have data for many more. Experience in macromolecular crystallography would be an advantage but enthusiasm for tackling challenging problems and experimental/stucture-solving skills are more important. The project is a long term one supported by the MRC with salaries age-related on the University scale. One of the posts might be of interest to someone wishing to join in the work for a sabbatical year.

Please apply in writing to Dr Olga Kennard, Chemical Laboratory, Lensfield Road, Cambridge CB2 1EW, UK, or telephone 0223 66499 ext 331. (6258)A

UNIVERSITY OF EDINBURGH
Reproductive Endocrinology Laboratory
DEPARTMENT OF OBSTETRICS AND GYNAECOLOGY
CENTRE FOR REPRODUCTIVE BIOLOGY

SENIOR LECTURER (non-clinical)

Applications are invited for the post of Senior Lecturer (non-clinical) in the above Department.

As Director of the Reproductive Endocrinology Laboratory, the successful applicant will be responsible for providing a limited range of hormone assays for clinicians in reproductive medicine. The salaries of 9 technicians, 2 secretaries and running costs are reimbursed by the Lothian Health Board In addition to service activities, the successful applicant will be expected to take advantage of the excellent opportunities for research available within the Centre for Reproductive Biology which contains the Department of Obstetrics and Gynaecology (Professor David T Baird) and the MRC Unit of Reproductive Biology (Director: Dr D W Lincoln)

The salary will be within the range £14,135 - £17,705 per annum together with superannuation under USS.

Further enquiries to: Professor David T Baird, Department of Obstetrics and Gynaecology, Centre for Reproductive Biology, 37 Chalmers Street, Edinburgh EH3 9EW. Tel No: 031-229 2575.

Further particulars may be obtained from the Secretary to the University, University of Edinburgh, Old College South Bridge, Edinburgh EH8 9YL, with whom applications (12 copies) including curriculum vitae and the names and addresses of three referees, should be lodged not later than 18/5/85.

Please quote Reference No 538. (6142)A

UNIVERSITY OF ABERDEEN

DEPARTMENT OF FORESTRY

'NEW BLOOD' LECTURER IN TREE BIOTECHNOLOGY

A 'New Blood' post is available in the above department specifically to develop the roles of tissue culture, micropropagation and protoplast fusion in the breeding of forest trees. This will be part of an existing tree breeding programme concentrating particularly on broadleaved species.

Candidates should possess, or be about to obtain, a PhD and have a degree or expertise in Genetics, Biochemistry or Developmental Biology. Experience in manipulation of protoplasts would be an advantage.

Salary will be on the Lecturer scale £7,520 — £14,925 per annum (scale under review) with appropriate placing

Further particulars and application forms from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 5 July 1985. (6272)A

Natural Environment Research Council

Environmental Research

Directors of Science

Swindon based **£29,500**

The Natural Environment Research Council wishes to appoint three new Directors to make a contribution at the highest level in the formulation and implementation of scientific policy in the following areas

Earth Sciences:
Geology, solid earth geophysics, geochemistry, glaciology and aspects of physical geography applied to the understanding of the origin and structure of the earth and the processes instrumental in its formation and evolution

Marine Sciences:
Physical, chemical and biological oceanography, ocean/atmosphere interaction, including meteorology, climatology and marine biology

Terrestrial & Freshwater Sciences:
Hydrology, hydrochemistry and freshwater biology, terrestrial ecology and related sciences, including forestry and land/atmosphere interactions

Responsible to Council through the Secretary and Chairman, the Directors will advise on the allocation of funds for research programmes at NERC establishments and in universities, and have overall responsibility for the management of resources and implementation of research programmes within their own field

Candidates for these posts should have the highest international scientific reputations and an overview of their Science across Research Councils, Universities and Industries They should also have experience in the management of research in particular and of resource management in general The appointments will be made at Grade 3 level on a salary of £29,500. Period appointment or secondment preferred though permanent appointment will be considered The individuals appointed will have offices at Swindon but will need to travel extensively A contribution towards relocation expenses may be made

Further details and an application form, indicating which Director post you are applying for, are available from Jem Purkis on Swindon (0793) 40101, ext 423 Completed applications should be returned by 31 May 1985 to Dr E Buttle at the Natural Environment Research Council, Polaris House, North Star Avenue, Swindon, Wiltshire, SN2 1EU

(6329)A

UNIVERSITY OF ARIZONA

STRATIGRAPHY

The Department of Geosciences at the University of Arizona invites applications for a tenure-track academic position in stratigraphy. We are particularly interested in candidates whose research efforts are directed toward the application of stratigraphy to problems in paleobiology, biostratigraphy, sedimentology, or paleotectonics We seek an individual capable of creative and interdisciplinary approaches to conceptual issues as well as practical problems in the paleobiological and sedimentological aspects of stratigraphy Duties include teaching undergraduate stratigraphy, developing graduate course material to complement and extend existing programs, advising students, directing graduate research and developing a vigorous research program.

Rank and salary will be commensurate with experience and qualifications The position will be available August, 1986, or sooner The Application deadline is August 15, 1985 All qualified persons are urged to apply

Applicants should send curriculum vitae, bibliography, statement and research interests, and names and addresses of four references to Dr. George H Davis, Department Head, Department of Geosciences, The University of Arizona, Tucson, Arizona 85721. The University of Arizona is an Equal Opportunity/Affirmative Action Employer

(NW1721)A

POSTDOCTORAL POSITIONS

Lipids-Atherosclerosis-Nutrition Training Program funded by NHLBI Postdoctoral traineeships are available for research and training in areas of a) lipoprotein stucture, b) apoplipoprotein metabolism, c) interaction of apoproteins with lipoprotein lipase, d) effect of diet on plasma lipoprotein and apolipoprotein content and metabolism, f) development of cholesterol and bile acid homeostatic mechanism, g) pathogenesis of atherosclerosis including the role of prostaglandins, h) role of branched chain amino acids in lipid metabolism and nutrition, i) vascular pathology in juvenile diabetes, j) modulation of lymphocyte physiology by membrane bound lipoproteins and k) eipdemiological and behavioural aspects of hyperlipoproteinemia. Faculty includes W F Balistreri, M.D., J.A K. Harmony, Ph.D , J.E Heubi, M.D , J.E. Fischer, M.D., C.J. Glueck, M D., R L. Jackson, Ph.D., M.L. Kashyap, M.D. J.M Vander Bel-Kahn, M.D., E.A Stein, M.D , M.T.R. Subbiah, Ph D. and R.C. Tsang, M.D

Candidates with a Ph.D. degree in biomedical or behavioural fields and those with M D. degree, with appropriate research exprience, are eligible to apply. Applicants must be U.S. citizens or hold an immigrant visa.

Send curriculum vitae with 3 letters of recommendation indicating the special area of research interest to: Dr. M.T.R. Subbiah, Program Director, Lipids-Atherosclerosis Nutrition Training Grant, University of Cincinnati Medical Center, 234 Goodman Street, K-Pavilion, M.L. 540, Cincinnati, Ohio 45267. (NW1719)A

COLAISTE NA HOLLSCOILE CORCAIGH
UNIVERSITY COLLEGE CORK

LECTURESHIP IN ZOOLOGY

Applications are invited from qualified zoologists with practical experience in aquaculture for a contract lectureship in Zoology, contributing to an interdisciplinary M.SC. programme in Aquaculture. Salary will be within the range IR £12,718 — IR £15,042 p.a.

Application forms and further information may be obtained from Professor M.F. Mulcahy, Department of Zoology, University College, Cork. Closing date for receipt of completed application forms is Friday, 24 May, 1985. (6330)A

UNIVERSITY CHEMICAL LABORATORY
Cambridge, UK

POST-DOCTORAL CHEMIST

Post-doctoral chemist with interest in molecular biology wanted to join a group of chemists and crystallographers working on the synthetic DNA fragments and complexes. The group has just completed the determination of several structures with base pair mismatches

Future plans include the study of DNA and RNA fragments of biological interest, some with novel modified bases. Work is also in progress on DNA-drug complexes.

The projects are exciting and exacting with good opportunities for gaining new expertise and building up a strong publication list. Experience of oligonucleotide of peptide synthesis would be an advantage, but it is not essential. The project is supported by the long-term MRC grant with adequate funds at the Research Assistant or Associate level, depending on age and experience.

Please apply in writing to Dr Olga Kennard, Chemical Laboratory, Lensfield Road, Cambridge, CB2 1EW, UK, or telephone 0223 66499 ext 331 (6257)A

UNIVERSITY COLLEGE CARDIFF

GEOLOGY DEPARTMENT

RESEARCH DEMONSTRATOR

Applications are invited for the post of Research Demonstrator in the Department of Geology, tenable for three years. Candidates should be pursuing a higher degree and preferably have had some relevant postgraduate experience. Interests may lie in any branch of the earth sciences though preference will be given to candidates with expertise in a major area of undergraduate teaching within the department.

Departmental commitments will amount to about 10 hours per week, plus occasional fieldwork in vacations. Salary will be within the range £6,600 — £7,980 per annum. Duties to commence 1st October or as soon as possible thereafter.

Applications, 2 copies, together with the names and addresses of two academic referees should be sent to the Establishment Officer, University College, PO Box 78, Cardiff CF1 1XL from whom further particulars are available. Closing date 24th May, 1985. Ref: 2942. (6251)A

ASSISTANT PROFESSOR

Yale University School of Medicine

Section of Neuroanatomy

NEUROBIOLOGIST

With experience in ultrastructural, pathway tracing, and immunohistochemical approaches to the analysis of organization and development of mammalian cerebral cortex. The position requires a small amount of teaching and organizing laboratory exercises for medical students.

Submit résumé to Chairman, Section of Neuroanatomy, Yale University, School of Medicine, New Haven, Ct. 06501. Yale is an Equal Opportunity/Affirmative Action Employer. (NW1708)A

NORTHWESTERN UNIVERSITY

Medical and Dental Schools

Department of Microbiology/Immunology and Cancer Center

POSTDOCTORAL POSITION

Applications are invited for a funded postdoctoral research position to study oncogene suppressors in human cells. Strong background in molecular biology preferred.

Applicants should send curriculum vitae and names, addresses and phone numbers of three references to: Dr Noel Bouck, Northwestern University, Department of Microbiolgy/Immunology, 303, E. Chicago Ave., Chicago, IL 60611. (NW1714)A

UNIVERSITY OF DURHAM

DEPARTMENT OF PHYSICS

Applications are invited for a

LECTURESHIP IN ASTRONOMY

tenable in the Department of Physics from 1 October 1985. Applicants with experience in any branch of observational or theoretical astronomy will be considered.

Starting salary on the scale (under review) £7,520 - £14,925 plus USS.

Applications (3 copies) naming three referees should be sent by 15 June 1985 to the Registrar, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. (6281)A

UNIVERSITY OF EDINBURGH

TEMPORARY LECTURER IN ZOOLOGY

Applications are invited for a temporary Lectureship in Zoology for one year only from 1 October 1985. This post is financed by the Nuffield Foundation and the maximum salary is point 4 of the Lecturer scale. The main teaching duties are in evolution and population biology. Further particulars can be obtained from the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh EH8 9YL with whom applications by letter (2 copies) including a curriculum vitae and the names of two referees should be lodged not later than 31 May 1985. Please quote reference number 1188. (6296)A

Southampton THE UNIVERSITY

INSTITUTE OF CRYOGENICS

Applications are invited for the post of Lecturer in the Institute of Cryogenics. Candidates should have a Ph.D. and research experience in applied low temperature physics or cryogenic engineering and a strong interest in teaching. The post will require development of links with industry via collaborative research and continuing education activities.

Salary within scale:— £7,520 — £14,925 per annum (under review). The appointment will be for an initial five year period.

Further particulars may be obtained from Mr. D.A.S. Copland, The University, Southampton SO9 5NH, to whom applications (7 copies from U.K. applicants) should be sent not later than 27 May 1985 quoting reference number 2155. (6282)A

UNIVERSITY OF GLASGOW

CHAIR OF COMPUTING SCIENCE

Applications are invited for a chair i computing science, in the area o computing systems design and imple mentation or in the practica application or computing languages databases, knowledge represen tation, special purpose compute architecture and graphics based man machine interfaces. The applican should have interests in one of thre topics or in a related area such a distributed processing, softwar engineering, or theoretical aspects o computing science.

The appointment will be tenabl from 1st October, 1985 or othe mutually convenient date.

Further particulars may b obtained from:— The Academi Personnel Office, University o Glasgow, Glasgow G12 8QQ, wher applications (3 copies, 1 copy in th case of overseas applicants), givin the names and addresses of thre referees, should be lodged on c before 10th June 1985.

In reply please quote Ref N 5472M. (6328)A

RESEARCH ASSOCIATE: PHYSIOLGY

Applications invited for the above post funded by the Muscular Dystrophy Group of Great Britain and Northern Ireland. Applicants should have a good honours degree in Physiology, Biochemistry or a related discipline. The appointment is temporary and begins on 1 October 1985.

Salary scale £6,600 — £8,920 with superannuation.

Further details can be obtained from Dr M E Smith (Tel 021 472 1301 ext 2446). Applications with curriculum vitae and the names and addresses of two referees should be sent to the Assistant Registrar, Medical School, Birmingham B15 2TJ by 21 May 1985. (6314)A

UNIVERSITY COLLEGE CARDIFF

BIOCHEMISTRY DEPARTMENT

RESEARCH ASSISTANT (3 YEARS)

Applications are invited for the above 3 year post on 'Comparative aspects of the effects of heavy metals on lipid metabolism and photosynthesis in marine algae'. Salary Grade 1B £6,600 — £7,520 per annum. Duties to commence 1st October, 1985.

Applications, 2 copies, together with the names and addresses of two referees should be forwarded to the Establishment Officer, University College, PO Box 78, Cardiff CF1 1XL. Further particulars are available from Professor J L Harwood, Tel: Cardiff 44211 ext 2268. . Closing date 23rd May, 1985. Ref: 2939 (6252)A

THE UNIVERSITY OF SYDNEY

School of Biological Sciences (Biophysics Laboratory)

POSTDOCTORAL FELLOW — Reference no 16/10

For research in plant electrophysiology. Experience in patch-clamp and/or perfusion techniques an advantage. A PhD in relevant area is required. Appointment is for two years.

Salary range: $A21,411 — $23,903 per annum (under review).

The University reserves the right not to proceed with any appointment for financial or other reasons.

Applications, quoting reference no, including curriculum vitae and the names and addresses of three referees, to the Registrar, University of Sydney, NSW 2006, Australia, by 31 May 1985. (W1834)A

UNIVERSITY OF EDINBURGH

DEPARTMENT OF ZOOLOGY

RESEARCH ASSOCIATE

Required to work on the molecular genetics of the cell cycle in fission yeast. The position, supported by the Cancer Research Campaign for a period of three years, is available immediately.

The project is concerned with the cloning and analysis of cell cycle genes and their products in fission yeast. The techniques employed will mainly be those of recombinant DNA and nucleic acid manipulations, yeast transformation, and genetic analysis.

Candidates should have experience in these areas and an honours degree in a relevant subject. Salary is according to age and experience on the RA 1B scale (£6,600 — £8,920).

Applications (2 copies) including a curriculum vitae and names and addresses of two referees, should be submitted by 24th May to Dr P A Fantes, Department of Zoology, University of Edinburgh, West Mains Road, Edinburgh, EH9 3JT, from whom further particulars may be obtained. Please quote reference number 5248. (6269)A

YOUNG RESEARCH worker required to participate in project on renal disease (hyperfiltration syndromes). The ability and dedication to carry out high precision radioimmunoassays (RIA) will be essential and familiarity with RIA and computer handling of data, an advantage. The project is suitable for work towards a higher degree. Salary up to £8,753, according to age and experience. The position is available for 3 years (first six months are a probationary period). Applications with full c.v. and names and addresses of 2 referees should be sent not later than (2 weeks after publication) to The Administration Officer, The Middlesex Hospital Medical School, Cleveland Street, London W1P 7PN. (6260)A

UNIVERSITY OF LEICESTER

DEPARTMENT OF GEOLOGY

EXPERIMENTAL OFFICER (COMPUTING) IN GEOPHYSICS

This new post is to provide laboratory, field and computing support in geophysics teaching and research programmes to members of staff.

Applications are invited from Science graduates with physics or geophysics or computer science training. Familiarity with BASIC and FORTRAN 77 will be an advantage.

Salary on the IB scale for Other Related Staff: £6,600 to £10,330 a year (under review).

Further particulars from the Registrar, University of Leicester, University Road, Leicester LE1 7RH, to whom applications should be sent on the form provided by 17 May 1985. (6279)A

LECTURER IN MINERALOGY AND GEOLOGY

Applications are invited for the above post, vacant as from 1st January 1986 Appointment will be made, according to qualification and experience, within the salary range R17 267 — 28 889 p.a. with an annual bonus and attractive staff benefits.

The successful applicant will be required to teach undergraduate courses in mineralogy and igneous petrology and to supervise postgraudate research in these fields Applicants should have a sound knowledge of these sub-disciplines and should be actively engaged in research.

Applicants should submit a full curriculum vitae stating present salary and the names and addresses of three referees not later than 31 July 1985 to the Registrar, (Attention: Appointments Office) AC/5413, University of Cape Town, Private Bag, Rondebosch, 7700, South Africa. Further information may be obtained from the Registrar or The Secretary, SA Universities Office, Chichester House, 278 High Holborn, London WC1V 7HE.

The University's policy is not to discriminate on the grounds of sex, race or religion. Further information on the implementation of this policy is obtainable on request. (W1835)A

MOLECULAR BIOLOGIST

Applications for an assistant professorship are invited from individuals with major commitment toward research and whose interests are in the structure, regulation or expression of viral, or mammalian, genes. Expertise in genetic engineering of enzymology-protein chemistry, an asset. Knowledge of or readiness to learn French essential. Send applications to: Dr Pierre Bourgaux, Directeur, Département de Microbiologie, Faculté de Médecine, Centre Hospitalier Universitaire, Université de Sherbrooke, Sherbrooke, Québec, Canada J1H 5N4. (NW1728)A

UNIVERSITY OF NEWCASTLE UPON TYNE

JUNIOR RESEARCH ASSOCIATE IN CELLULAR IMMUNOLOGY

Applications are invited from graduates in biological sciences for the post of Junior Research Associate to join a project studying the mechanism of antigen presentation to T lymphocytes, which is funded by the MRC.

The post is available for two years from 1st August 1985. Commencing salary up to £7,980 per annum on the National Range 1B salary scale £6,600 - £8,920.

Written applications including full curriculum vitae and the names and addresses of three referees to Dr John H Robinson, Department of Anatomy, University of Newcastle upon Tyne, Newcastle upon Tyne NE2 4HH. Tel 0632 328511 Ext 2946 not later than 23rd May 1985. (6303)A

THE BEATSON INSTITUTE FOR CANCER RESEARCH GLASGOW

POSTDOCTORAL RESEARCH SCIENTIST

A vacancy is immediately available for a postdoctoral research scientist to study the involvement of cellular genes in benign and malignant human tumours associated with papillomaviruses. The appointee will join a group studying gene organization and expression of papillomaviruses, their involvement in oncogenesis, and the cellular response to viral infection and transformation.

He/She will collaborate with other members of the group and will have ample opportunities for interaction with other scientists both within the Institute and in the University scientific departments, the Medical School and the Veterinary School. Excellent facilities and supporting background in molecular biology, virology and cell biology are available.

Applicants should have a PhD in molecular or cell biology, and experience with current techniques in manipulation of nucleic acids is essential.

The post is funded by the Cancer Research Campaign, and the appointment will be for three years, with possibility of extension to five, at an appropriate point on the University Research Grade IA Scale (£7,520—£12,150 per annum) according to qualifications and experience.

Applications, together with full CV and the names of two referees, should be sent to Dr M Saveria Campo, The Beatson Institute for Cancer Research, Garscube Estate, Switchback Road, Bearsden, Glasgow G61 1BD (6259)A

THE UNIVERSITY OF MANITOBA
Department of Microbiology

PROFESSOR AND HEAD OF DEPARTMENT

The department of microbiology is a constituent department of the Faculty of Science and has broad responsibility for the teaching of microbiology in honours and majors programs in biochemistry and genetics. The department has twelve full-time faculty members and offers M Sc. and Ph.D programs in a spectrum of prokaryotic and eukaryotic microbiology, molecular biology, and biochemistry

The university encourages both women and men to apply for positions. In accordance with Canadian immigration requirements, this advertisement is directed to Canadian citizens and permanent residents. **Deadline for applications is July 1, 1985.**

Applications should be directed to: **P.K. Isaac, Chair, Microbiology Headship Selection Committee, University of Manitoba, Faculty of Science, 250 Machray Hall, Winnipeg, Manitoba, Canada, R3T 2N2.** (NW1723)A

UNIVERSITY OF ULSTER
Faculty of Science

RESEARCH OFFICER, BIOMEDICAL SCIENCES

Ref: C85/82

(One year appointment at Coleraine)

To undertake an investigation, sponsored by the Department of Health and Social Services and the Ulster Cancer Foundation, into the influence of macrophage-derived products on the suppression of T-lymphocyte proliferation in cancer patients

Applicants should hold, or expect to obtain in the near future, a PhD in the area of Cell Biology/Cellular Immunology.

Salary for this appointment, tenable initially for one year from 1 August 1985, will be determined by age, qualifications and experience within the range £7,520 — £8,920 per annum of the Research and Analogous 1A Scale (under review)

Further details are available from the Staffing Office, University of Ulster at Coleraine, Cromore Road, Coleraine, Co Londonderry BT52 1SA (Telephone Coleraine 4141, Ext 225) to whom applications, including a full curriculum vitae and the names and addresses of three referees, should be sent not later than 17 May 1985. (6309)A

ST MARY'S HOSPITAL MEDICAL SCHOOL
(University of London)
Norfolk Place,
London W2 1PG

DEPARTMENT OF BIOCHEMISTRY

POST-DOCTORAL RESEARCH ASSISTANT

Applications are invited for the above post to work on a MRC funded project on the microdissection and microcloning of the mouse X-chromosome. The project involves the construction of detailed molecular maps of individual regions of the mouse X-chromosome for the isolation and characterisation of interesting genetic loci, in particular mdx (X-linked muscular dystrophy). The applicant should have experience of recombinant DNA technology.

The post is available immediately. Salary is on the 1A scale (starting point, £7,520 plus £1,233 pa London Allowance) for research staff.

Enquiries to Dr S D M Brown tel (01) 723-1252 ext 333. Applications including full cv and names and addresses of 2 referees to Assistant Secretary (Personnel) at above address by 13 May 1985. (6322)A

TRENT POLYTECHNIC
Department of Life Sciences

RESEARCH ASSISTANT/ DEMONSTRATOR

(£5,910 — £6,657)

Honours graduates with a first or second class Honours degree or equivalent in an appropriate Biological discipline are invited to apply for a research project which will lead to an M Phil or PHD Degree. The successful candidate will be appointed to one of the following projects:

i. The Effects of Mine Effluents on Fresh Water Invertebrate Animals (E/204)
ii. Protein Profiles in Physiological Fluids in Health and Disease (E/206)
iii Proteolytic Enzymes of Plants (E/203)

Please state the ref no of the Project for which you wish to apply.

Further details and application forms are available from the Staff Officer, Trent Polytechnic, Burton Street, Nottingham NG1 4BU. Tel (0602) 418248. Closing date 17 May 1985. (6294)A

SOUTH MANCHESTER HEALTH AUTHORITY
CHRISTIE HOSPITAL & HOLT RADIUM INSTITUTE
Paterson Laboratories

SENIOR RESEARCH TECHNICIAN

Required in the Department of Molecular Biology at The Paterson Laboratories, a large multidisciplinary cancer research institute.

Applications are invited from enthusiastic, independent research-orientated technical personnel to join a team working on the molecular biology of Epstein-Barr Virus and its relationship to human cancer.

In addition to performing research activities, the successful candidate is expected to organize and supervise four other technical staff in the day-to-day running of the laboratory and to take charge of orders and accounts.

Applicants should have several years' relevant experience, preferably in molecular biology or related disciplines. Experience in handling tissue culture cells would be an advantage. Salary within the scale £7,521 - £9,935 pa, (under review), according to age, qualifications and experience.

Further information can be obtained from Dr J A Arrand, Tel 061-445 8123 ext 557.

Send sae for application form to the Laboratory Administrator, Paterson Laboratories, Christie Hospital, Wilmslow Road, Manchester M20 9BX, quoting reference PL/85/4. Closing date: 13 May 1985. (6316)A

PHARMACIST INDUSTRIAL

to supervise and coordinate research to develop parenteral emulsions for pharmaceutical use Applicant must have a Ph.D. in Pharmaceutical Sciences with two years of industrial experience in research and development of lipid emulsion products for parenteral, oral and topical use. Salary $40,800. per year Job in Menlo Park, CA.
Please send résumé to Job No. 2895, P.O. Box 865, Sacramento, CA 95804 not later than May 17, 1985. (NW1718)A

OXFORDSHIRE HEALTH AUTHORITY
Chest Unit Churchill Hospital

SENIOR PULMONARY FUNCTION TECHNICIAN

required to run small laboratory and to be responsible for the current research programme. Ideal for recently qualified staff or graduate with some experience as medical physics technician. The position is for 2 years duration.

Salary dependent on qualifications and experience commencing at £5,404/6,408.

For application form and job description apply to the Personnel Officer, Churchill Hospital, Headington, Oxford. Tel. Oxford 64841 Ext. 228. (6324)A

IMPERIAL CANCER RESEARCH FUND
RESEARCH FELLOW

required for post-doctoral appointment to work on murine immunogenetics, immunoregulation, and/or lymphocyte development and activation at the Fund's Tumour Immunology Unit, at University College Medical School, London WC1.

Appointment for three years. Salary range £10,220 to £12,505 entry depending on qualifications and experience.

Applications with CV and names and addresses of three referees should be sent to: Professor N A Mitchison, FRS, Tumour Immunology Unit, University College London, Gower Street, London, WC1E. (6226)A

POSTDOCTORAL POSITION

The Division of Oncology, Department of Medicine, University Hospital of Zurich, Switzerland. Ph.D. in biochemistry, biology or related field, to study surface antigens and transformation processes of human respiratory tumors. Duration two, possibly three years Experience in purification of membrane antigens, immunochemistry or recombinant DNA techniques desirable.

Please send CV and names of three referees to: Dr Rolf A. Stahel, Box Number NW1713, c/o Nature, 65 Bleecker Street, New York, NY 10012. (NW1713)A

MEDICAL RESEARCH COUNCIL

National Institute for Medical Research

Scientific Appointment in the Laboratory of Gene Structure and Expression

Applications are invited for a scientific position in the Laboratory of Gene Structure and Expression, (Head: Dr F.G. Grosveld) in the field of studies on the regulation of globin gene expression. The candidate will be expected to carry out independent research and should preferably have postdoctoral experience in the globin-DNA field. Extensive experience with recombinant DNA technology and tissue culture techniques is definitely required

The position might be filled either by a career or a short-term appointment, according to the age and experience of the candidate.

The salary will be at an appropriate point on the Council's range equivalent to University non-clinical academic staff scales, plus £1,233 London allowance and superannuation provision.

Applications, giving the names of three persons to whom reference may be made, should be made not later than 31st May 1985 to the Director, National Institute for Medical Research, Mill Hill NW7 1AA. Please quote ref: GSE/10/C. (6323)A

MEDICAL RESEARCH COUNCIL
National Institute for Medical Research
Computing Laboratory

COMPUTING TECHNIQUES IN SEQUENCING

Applications are invited for a short term non-clinical scientific appointment, tenable for 3 years, from candidates with experience of the use of computing techniques in DNA and protein sequencing. The successful applicant will be expected to set up facilities in the Institute for the handling of international sequence data banks and for the manipulation of experimental data.

Renumeration will be at an appropriate point on the scales for university non-clinical academic staff plus £1,233 London allowance and Superannuation provision.

Applications, together with a full curriculum vitae and the names of two professional referees should be sent to the Assistant Director, National Institute for Medical Research, Mill Hill, London NW7 1AA by 31 May 1985 quoting reference C/1/G.

The successful candidate will be expected to start not later than 1st August 1985. (6313)A

POSTDOCTORAL RESEARCH ASSOCIATE; (In a research setting). Chemist to conduct research work in Organic Chemistry on the synthesis of derivative of Adamantane and Diamantane and their possible polymerization. PhD in Organic Chemistry. Must have manipulative and maintenance knowledge of NMR, IR, MS, and GC. Job Site: Los Angeles. Salary $1605 per month. Send this ad and your résumé to: Job 7573, PO Box 865, Sacramento, California 95804, no later than May 3, 1985. (NW1673)A

THE DANA FARBER CANCER INSTITUTE

Is seeking to fill one research position at the Assistant Professor level. Joint appointment will be held in an appropriate department at Harvard Medical School. Candidates should be qualified to develop an interactive research program emphasizing the molecular biology of lymphocyte cell surface antigens, should hold a doctoral degree (M.D. and/or Ph.D) and, preferably, should have postdoctoral research experience in a related area

Applications should submit a résumé, list of publications, statement of research interests and the names and addresses of 3 references to Dr. David Kiszkiss, Director for Research, DANA-FARBER CANCER INSTITUTE, 44 Binney St., Boston, MA 02115. An Affirmative Action/Equal Opportunity Employer.
(NW1709)A

ROYAL HOLLOWAY AND BEDFORD COLLEGES

RESEARCH ASSISTANT

Applications are invited from Physicists, Engineers or Applied Mathematicians, to join a team engaged in a range of projects on fundamental aspects of Electromagnetic Antennas for Millimetric Wavelenghts. This project involves both theoretical work (using analytical and computational techniques) and supporting experimental studies in one or more of the following areas:—

(1) Electromagnetic Theory

(2) Numerical Control Engineering

(3) Applied Optics

Candidates should have an aptitude for research and a good degree or a postgraduate qualification in a relevant subject. Salary scale £9,863 – £11,093 (under review).

Applications (2 copies) with curriculum vitae and names and addresses of 2 referees should be sent immediately to the Personnel Officer, Royal Holloway and Bedford Colleges, Egham Hill, Egham, Surrey TW20 0EX.
(6318)A

Central Haematology Laboratory Inselspital, Berne, Switzerland

Applications are invited for the post of

RESEARCH BIOCHEMIST
(POSTDOCTORAL RESEARCH FELLOW)

for a period of two years which may be renewed upon mutual agreement. The post is available immediately. The project is concerned with the relationship between structure and function of factor VIII/von Willebrand factor Candidates should have experience in biochemistry of biological macromolecules and interest in clinically oriented research. Salary will be approximately SFr. 4500.-- per month before taxes

Applications including a curriculum vitae and the names of two referees, should be sent to:- Prof. M. Furlan, Central Haematology Laboratory, Inselspital, CH-3010 Bern.
(W1833)A

RESEARCH SCIENTIST

Research in protein chemistry, enzyme chemistry, yeast cell biology and yeast molecular biology including cloning and expression of genes in yeast. PhD in Biochemistry and 2 years experience in research of yeast cell and molecular biology required. Job site. La Jolla Salary. $42,800 per year. **Send this ad and your résumé to Job 2796, P.O. Box 865, Sacramento, CA 95804 not later than 5/20/85.**
(NW1722)A

ROYAL HOLLOWAY AND BEDFORD COLLEGES

NEW BLOOD LECTURESHIP IN GEOPHYSICS

For research in the fields of seismic reflection processing, modelling and interpretation and to assist in teaching a new MSc course in Basin Evolution and Dynamics. The new Geology Department will be based at Egham and is being created by the amalgamation of the Departments from Bedford, Chelsea and King's Colleges.

Salary scale £8,753 — £16,158 including London Allowance. Candidates must be under 35 years of age.

Please send a self addressed envelope for further details to: Mrs D J Odds, Personnel Officer, Royal Holloway and Bedford College, Egham Hill, Egham, Surrey TW20 0EX, to whom applications (two copies) with cv and the names and addresses of two referees should be sent. Closing date 15th June 1985.
(6319)A

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF ANCIENT HISTORY & ARCHAEOLOGY

SOIL SCIENTIST

Applications are invited for a Research Associateship to work on soils and sediments associated with archaeological horizons in deposits in a Wiltshire river valley. Applicants should have a degree which includes a substantial soil science component. The appointment is funded by the SERC and is for up to three years from 1 July 1985 or as soon as possible thereafter.

Salary on the scale: £6,600 — £8,920.

Applications (six copies), naming three referees, should be sent by 28 May 1985 to the Assistant Registrar (Arts), University of Birmingham, PO Box 363, Birmingham B15 2TT, from whom further particulars may be obtained. (6315)A

POSTDOCTORAL POSITION

available to determine DNA sequences essential for the transcriptional expression of T-DNA and higher plant genes. The research involves cloning, *Agrobacterium* vector construction, *in vitro* mutagenesis, transcript mapping and characterization of chimeric plant promoters. Experience in recombinant DNA technology, DNA sequencing and plant molecular biology desirable.

Send curriculum vitae and the names of three referees to: William B. Gurley, Department of Microbiology and Cell Science, 1059 McCarty Hall, University of Florida, Gainesville, Florida 32611. *An equal opportunity/affirmative action employer.* (NW1725)A

Research Award in Immunoregulation

Centocor, Inc., will award a $10,000 unrestricted research grant for the most outstanding human Interferon-Gamma scientific paper published (or accepted for publication) between 1/1/85 and 6/30/86.

For details, write to Centocor customer service.

STUDENTSHIPS

UNIVERSITY OF OXFORD
Dyson Perrins Laboratory
(Organic Chemistry)

CASE STUDENTSHIPS

Applications are invited from suitably qualified graduates, or from those expected to graduate shortly, for two SERC financed CASE studentships in synthetic organic chemistry. One is concerned with thiotetronic acid synthesis, the other is involved with the development of a total synthesis of some macrocyclic diterpenes.

The studentships are tenable from 1st October 1985. Applicants should write, giving the names of two referees, as soon as possible to Dr E J Thomas, The Dyson Perrins Laboratory, South Parks Road, Oxford, OX1 3QY. (6253)F

UNIVERSITY OF OXFORD
Dyson Perrins Laboratory

RESEARCH STUDENTSHIPS

Applications are invited for research studentships in the following areas (i) Organic Synthesis:- asymmetric carbon-carbon bond formation using chiral organoiron auxiliaries (ii) Organotransition Metal Chemistry:- mechanistic studies related to the reactions of metal carbonyl ligands.

The studentships leading to the degree of D Phil are for three years from October 1st 1985. Applications with curriculum vitae and names of two referees, as soon as possible to Dr Stephen G Davies, Dyson Perrins Laboratory, South Parks Road, Oxford, OX1 3QY (6254)F

UNIVERSITY OF OXFORD
Department of Human Anatomy

The Department of Human Anatomy invites applications from students interested in post-graduate study. Developmental biology, neurobiology, endocrinology, or membrane physiology are currently active areas. Radioimmunoassay, autoradiography, tissue culture, electron and scanning electron microscopy and quantitative image analysis are among the facilities offered by the Department. Details of research in the Department can be obtained by applicants.

Applicants, who should have or expect to obtain a good honours degree, should send a copy of their curriculum vitae, a statement of their research interests and the names of three referees to Professor R W Guillery FRS, Department of Human Anatomy, South Parks Road, Oxford, OX13QX, by 14 May 1985. (6271)A

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF BIOCHEMISTRY

The department has

5 STUDENTSHIPS

available for research leading to the degree of PhD. These include 1 MRC, 2 SERC and 2 SERC-CASE studentships for work in the fields of cell biology, enzymology, microbial biochemistry and bioenergetics.

Applications with curriculum vitae and the names, addresses and telephone numbers of 2 referees should be sent to Dr A G Lee, Department of Biochemistry, University of Southampton, School of Biochemical and Physiological Sciences, Bassett Crescent East, Southampton, SO9 3TU. (6300)F

UNIVERSITY OF SOUTHAMPTON
Clinical Pharmacology/Medicine 1

SERC (CASE) Studentships

Applications are invited from good honours graduates in pharmacology, biochemistry or physiology for the following SERC (CASE) studentships to study:

1. The biochemical pharmacology of dispersed human skin mast cells (in collaboration with Roussel Laboratories Limited).

2. The development of bronchial hyper-reactivity in the guineapig (in collaboration with Roussel Laboratories Limited).

3. The oxidative metabolism of arachidonic acid in human and primate mast cells (in collaboration with Frisons Pharmaceuticals PLC).

The studentships are available for 3 years from October 1st 1985 and the successful applicants expected to register for a higher degree. Further information and applications, including curriculum vitae and the names of two referees to: Dr M K Church, Clinical Pharmacology, Southampton General Hospital, Southampton S09 4XY. Telephone 0703-777222 Ext 4312. Applications close June 3rd 1985. Please quote ref no AJS/85/26. (6273)F

UNIVERSITY OF LEICESTER
SCHOOL OF BIOLOGICAL SCIENCES
(BOTANY DEPARTMENT)

SERC — CASE STUDENTSHIP
(ICI Corporate Biosciences Group)

An SERC-CASE Studentship in collaboration with Dr W Schuch of the ICI Corporate Biosciences Group is available to work on 'Photocontrol of phenylalanine ammonia-lyase mRNA levels in oil-seed rape seedlings under radiation conditions simulating crop stands'. This project is concerned with the molecular biology of phytochrome action in light-grown plants, with particular respect to the control of growth and lignification in crop plants experiencing mutual shading. The work will involve the use of cDNA probes to estimate PAL mRNA levels and to measure specific transcription rates. An academic background in molecular biochemistry would be an advantage; prior experience with plants is useful but not essential and training will be given in plant photomorphogenesis.

Applicants having, or expecting to achieve, at least an Upper Second Class Honours Degree in an appropriate subject should submit a curriculum vitae, with the names of two referees, as soon as possible to Professor H Smith, Department of Botany, University of Leicester, University Road, Leicester. (6290)F

Medical Research Council Research Studentship (Partnership Award)

University Laboratory of Physiology, Oxford and the National Institute for Medical Research, Mill Hill, London

A 3-year M.R.C. Studentship leading to a D.Phil. is available from 1st October 1985, for a project investigating contractile mechanisms in 'skinned' muscle fibres employing 'caged' ATP and the fluorescently labelled derivative of the calcium sensitive regulatory protein, troponin (TnC-DANZ). The training will involve the combination of physiology and biochemical methods, particularly the use of novel optical and laser techniques in muscle research, introduced by Dr C.C. Ashley and Dr. D.R. Trentham, F.R.S., the co-supervisors of the project.

The overall aim is to correlate mechanical and biochemical experiments on skinned muscle fibres with those on intact fibres in order to provide a clearer insight into the basic contractile mechanism and its regulation.

Applicants should have or expect to obtain a 1st or upper 2nd class honours degree, and have a background in physiology, biochemistry or physical sciences.

Applications including a CV and the names and addresses of 2 referees should be sent to Dr C.C. Ashley, University Laboratory of Physiology, Parks Road, Oxford OX1 3PT, as soon as possible. (6312)F

UNIVERSITY OF ST ANDREWS
DEPARTMENT OF PHYSIOLOGY AND PHARMACOLOGY

RESEARCH STUDENTSHIPS

The department occupies two sites — at the Bute Medical Buildings and the Gatty Marine Laboratory. Excellent facilities are available for research in the following areas: cell physiology, neurobiology and neuropharmacology, muscle physiology, human exercise and respiratory physiology and environmental biology. The following Research Council studentships are available:

1 "Effects of temperature on muscle contraction in fish" or "Hypoxia and activity metabolism in fish" supported by NERC under the supervision of Dr Ian A Johnston.

2 SERC-CASE studentship on "Physiological, neuroanatomical and biochemical studies on the function of dopamine in the insect nervous system" under the joint supervision of Dr Robert M Pitman and staff at The Wellcome Research Laboratories, Berkhamstead.

3 MRC studentship in muscle and cell physiology.

Further particulars of the department and research projects may be obtained from Mrs M Noble, Secretary, Department of Physiology and Pharmacology, Bute Medical Buildings, University of St Andrews, St Andrews, Fife KY16 9TS, Scotland, to whom applications (which should include a full curriculum vitae and the names of two referees) should be sent to arrive not later than 20 May 1985. (6297)F

SERC STUDENTSHIP IN SEA-USE

The London School of Economics is offering two Advanced Course studentships, funded by the Science and Engineering Research Council, on its MSc Sea-Use Programme for the academic year 1 October 1985 — 30 September 1986. Preference will be given to applicants possessing a good first degree in economics who wish to specialise in the economics option; but applications from other specialities such as law, engineering, political science, history, geography or environmental studies will be considered. The programme consists of a basic course in Marine Science, Biology and Technology, with a choice of two options chosen from: International Law of the Sea, Financial Reporting and Management, Economics and Problems of Sea-Use Policy-Making, together with a research essay of 10,000 words on an agreed topic.

Candidates should write at once to the Secretary of the Graduate School, The London School of Economics and Political Science, Houghton Street, London WC2A 2AE, for application material. (6270)F

KINGSTON POLYTECHNIC
School of Industrial, Organic and Polymer Chemistry

SERC "CASE" STUDENTSHIPS

Applications are invited from good honours graduates in chemistry, materials technology or related subjects for three SERC "CASE" Studentships concerned with organic polymer composites. All projects involve industrial collaboration (ICI, Westland Helicopters, National Physical Laboratory) in the study of the properties of fibre reinforced polymers using instrumental methods.

Application forms and further details from Staffing Officer, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. Tel 01-549 1366 ext 205. (6278)F

UNIVERSITY OF SOUTHAMPTON
FACULTY OF MEDICINE
DEPARTMENT OF CLINICAL PHARMACOLOGY

RESEARCH STUDENTSHIP

Applications are invited for a research studentship within the Clinical Pharmacology Group to study the pharmacokinetics of therapeutically used amino acids such as L-dopa and tryptophan. Applicants should have a first or upper second-class honours degree in Pharmacology, Biotechnology or a related subject. The studentship will be for three years but the successful applicant will be expected to register for a PhD. The grant will be at the appropriate MRC rate.

Applications (2 copies) giving a full curriculum vitae and the names, addresses and telephone numbers of two referees should be sent to Dr A G Renwick, Department of Clinical Pharmacology, University of Southampton, Basset Crescent East, Boldrewood, Southampton, Hampshire from whom further details may be obtained. Please quote Ref: AJS/85/25. (6265)F

UNIVERSITY OF READING
DEPARTMENT OF PURE & APPLIED ZOOLOGY

STUDENTSHIPS

for postgraduate study are available in the following areas:

1. Animal behaviour in wild and domesticated mammals.
2. Genetics aspects of development or competition between insects.
3. Effects of parasite infections.
4. Evolution of life cycle strategies.
5. Mechanical properties of biological materials.
6. Metal or pesticide accumulation and detoxification.

Applicants should send a curriculum vitae with the names of two referees to Professor K Simkiss, Department of Pure & Applied Zoology, University of Reading, PO Box 228, Reading, RG6 2JN. (5727)F

ROYAL POSTGRADUATE MEDICAL SCHOOL

MRC RESEARCH STUDENTSHIP

Applications are invited for a three year MRC Studentship from graduates holding, or expecting to obtain, an upper second second or first class honours degree. The successful candidate will work on the measurement and pathophysiology of novel peptide neurotransmitters.

Applications in the form of cv with the names of two referees together with a letter of application should be sent to Professor S R Bloom, Department of Medicine, Royal Postgraduate Medical School, 150 Ducane Rd, W12 OHS from whom further particulars may be obtained.

Closing Date: 23 May 1985.
(6320)F

UNIVERSITY OF OXFORD

NUFFIELD DEPARTMENT OF OBSTETRICS AND GYNAECOLOGY

Applications are invited for an MRC research studentship leading to a D Phil, tenable for 3 years from October 1985, under the direction of Dr Phyllis Starkey. Applicants should have (or be about to obtain) a good Honours degree in a biological science.

The successful applicant would investigate the cellular and enzymic basis of ripening of the cervix in labour, as part of a Department studying various aspects of human pregnancy and labour including the immunological interaction between mother and fetus, the causes of pre-eclampsia and recurrent abortions, the factors controlling the initiation of labour, and the cell biology of the human decidua, placenta and fetal membranes.

Further details from, and applications to: Dr Phyllis Starkey, Nuffield Department of Obstetrics and Gynaecology, John Radcliffe Hospital, Headington, Oxford. Closing date 31st May 1985.
(6311)F

KING'S COLLEGE LONDON (KQC)

DEPARTMENT OF PHYSIOLOGY

SERC - CASE STUDENTSHIP

Applications are invited for a collaborative studentship under the SERC - CASE scheme between the above department and the National Institute of Biological Standards, Hampstead. The project will involve studies of the biosynthesis, secretion and characterisation of the 'major proglucagon fragment' which is produced together with glucagon by the pancreatic A cell.

Applicants should have, or expect to obtain, a first or upper second class honours degree in Biochemistry, Physiology or a related subject. Applications, including a curriculum vitae and the names of two referees, should be sent to Dr S L Howell, Physiology Department, Queen Elizabeth College, University of London, Campden Hill Road, Kensington, London W8 7AH by 17th May 1985.
(6284)F

MEDICAL RESEARCH COUNCIL

Mechanisms in Tumour Immunity Unit

RESEARCH STUDENTSHIP

Applications are invited for a Research Studentship, tenable for a three year period, from Autumn 1985 to work on one of two projects:

1 Investigation of the inhibitory profile of C1-inhibitor — a plasma protease inhibitor active against both complement and coagulation proteases.

2 Growth factors involved in the establishment of a human B lymphoblastoid (EBV) lines.

The successful candidate should possess by Autumn 1985 a good honours degree in either biochemistry or a biological science and will be expected to register for a PhD with the University of Cambridge.

Applications, including a full curriculum vitae and the names and addresses of two referees, should be sent to: Professor P J Lachmann, MITI Unit, MRC Centre, Cambridge CB2 2QH by 16th May 1985.
(6299)

UNIVERSITY OF LEICESTER

DEPARTMENT OF MICROBIOLOGY

SERC CASE STUDENTSHIP

Applications are invited for a CASE studentship to study the expression of eukaryotic genes in Pseudomonas putida and Methylophilus methylotrophus, in collaboration with Dr G S Sharpe, Corporate Biosciences Laboratory, ICI.

Applicants should possess, or expect, a first or an upper second class degree in biochemistry, genetics or a related field.

Applications, in the form of a curriculum vitae with the names of two academic referees should be sent to Dr G J Boulnois, Dept of Microbiology, Medical Sciences Building, University Road, Leicester LE1 7RH (Tel. 0533-551234, ext 262).
(6292)F

UNIVERSITY OF ABERDEEN

DEPARTMENT OF GENETICS

NERC CASE RESEARCH STUDENTSHIP

Applications are invited for the above studentship to work on an investigation of marine polychaetes as indicator organisms for genotoxic effects of pollutants. The project will be jointly supervised by Dr D P Fox of Aberdeen University, Genetics Department and Dr J Davies, DAFS Marine Laboratory, Aberdeen.

Candidates should hold, or expect to obtain, first or upper second class honours in Genetics or another appropriate biological subject.

Applicants should send a curriculum vitae together with the names of two referees to Dr D P Fox, Department of Genetics, University of Aberdeen, 2 Tillydrone Avenue, Aberdeen, AB2 2TN not later than Friday 17th May. Informal enquiries may be made to Dr Fox, tel: 0224-40241 ext 6455. (6255)F

QUEEN MARY COLLEGE (University of London)

DEPARTMENT OF CHEMISTRY

SERC-CASE RESEARCH STUDENTSHIPS

Applications are invited for the following Research Studentships awarded under the SERC Cooperative Awards in Science and Engineering schemes for October 1985 The Chemistry Department has recently expanded considerably with the restructuring of experimental science in the University of London.

Dr P A Hamilton — 'Mechanism of Atmospheric Sulphur Reactions' (with Central Electricity Research Laboratory)

Dr. P. O'Brien — 'Novel Precursors for the Deposition of Cadmium Sulphide for MOCVD' (with Polaron Equipment Ltd.)

Professor J. Pritchard — 'Hydrogen Chemisorption on Copper Catalysts' (with ICI Agricultural Division)

Dr N S Simpkins — 'Asymmetric Synthesis of Potential Inhibitors of 5-Lipoxygenase' (with May and Baker Ltd.)

Professor J.H.P. Utley — 'Electrosynthesis of Liquid Crystals and Related Intermediates' (with BDH Chemicals Ltd.)

Dr. D.S. Urch — 'High Resolution XRF-XPS: Electronic Structure and Analysis' (with Health and Safety Executive)

Further information on any of these projects can be obtained from the appropriate supervisor. Applicants must have, or expect to obtain this year, a degree in chemistry with at least upper second class honours. Application forms from Dr. J.R.C. Light, Chemistry Department, Queen Mary College, Mile End Road, London E1 4NS to be returned as soon as possible.
(6321)F

LONDON SCHOOL OF HYGIENE & TROPICAL MEDICINE

(University of London)
Keppel Street,
London, WC1E 7HT

SERC CASE STUDENTSHIP IN IMMUNOLOGY

Applications for a Research Studentship leading to a PhD degree are invited from candidates who hold or expect to obtain this summer a first or upper second class honours degree in a biological science. Experience in Immunology is desirable but not essential. The studentship is tenable at the School, in conjunction with Imperial Chemical Industries, from October 1st 1985. The project will be supervised by Professor M W Steward of the Immunology Unit, Department of Medical Microbiology and Dr A F Wright of ICI and will be concerned with the production and control of high affinity antibody responses.

Applications, including a full cv and the names of two referees, should be sent to Professor Steward at the School. (6283)F

UNIVERSITY OF YORK

DEPARTMENT OF BIOLOGY

SERC CASE STUDENTSHIP

Applications are invited for a SERC CASE Studentship to work with Dr A W Robards in collaboration with ICI Agricultural Division on "Separation of subcellular granules from bacterial cells". It is expected that the appointed student would have a background in micro-biology and/or cell biology and should have a strong interest in applications of cell biology to biotechnology.

Applications should be made to Dr Robards, Department of Biology, University of York, Heslington, York, YO1 5DD from whom further details can be obtained. Candidates must be ordinarily resident in Great Britain and should have (or expect to obtain) a First or Upper Second Class Honours Degree from a British University or Polytechnic.
(6275)F

UNIVERSITY OF GLASGOW

DEPARTMENT OF BIOCHEMISTRY

CASE STUDENTSHIP

Applications are invited for a CASE studentship, in collaboration with the Agricultural Scientific Service of the Department of Agriculture and Fisheries for Scotland at East Craigs (Edinburgh) and the Scottish Crop Research Institute (Invergowrie), to study the role of components of the outer membrane in the antigenic properties of soft rot Erwinia species that are pathogenic to potatoes.

Candidates should have, or expect to attain this summer, a good honours degree in biochemistry or a related discipline.

Further information can be obtained from Dr I D Hamilton, Department of Biochemistry, University of Glasgow, Glasgow G12 8QQ, to whom application, including a curriculum vitae and nominating 2 academic referees, should be made by 31st May, 1985. (6310)F

UNIVERSITY OF DURHAM

DEPARTMENT OF BOTANY

Applications are invited for a

RESEARCH STUDENTSHIP

funded by the SERC CASE award scheme to work on the Structure and Evolution of cereal grain proteins. The research will be with Dr M Richardson at the University of Durham and Dr P Shewry (Biochemistry Department, Rothamsted Experimental Station) and involves protein chemistry (amino acid sequencing), molecular biology and recombinant DNA techniques. It is envisaged that the student's time will be split equally between the two Institutes.

Applicants should have, or expect to obtain, a first or upper second class honours degree, preferably in biochemistry, botany or a biological science.

Applications (cv and the name of two referees) should be sent to Dr M Richardson, Department of Botany, University of Durham, Science Laboratories, South Road, Durham DH1 3LE no later than 6 June 1985.
(6282)F

STUDENTSHIPS Continued

ASTON UNIVERSITY
Department of Pharmaceutical Sciences
RESEARCH STUDENTSHIPS
in the Pharmaceutical Sciences Institute

The Pharmaceutical Sciences Institute has been established to coordinate the research work of the Department of Pharmaceutical Sciences. The Institute is concentrating its resources within well-funded research groups and the following research areas will be supported in work commencing 1 October 1985.

Targeting of Drugs by Phagocytic Cells: SERC CASE Studentship (Ciba-Geiby)	(Dr D A Lewis)
Hypoxia, Ischaemia and Peripheral Vasodilator Mechanisms: SERC CASE Studentship (ICI Pharmaceuticals)	(Dr O A Downing)
Drug-delivery Systems Design	(Dr W J Irwin)
Computer-graphics Aided Design and Synthesis of Chemotherapeutic Agents	(Prof M F G Stevens)
Cardiovascular Pharmacology	(Prof C B Ferry)
Microbiology	(Prof M R W Brown)
Cancer Chemotherapy	(Dr J A Hickman)
Toxicology	(Dr E S Harpur

A number of research studentships will be available for highly qualified graduates, or those expecting to graduate in 1985, to work on a variety of topics leading to the award of PhD degrees. The named individuals should be contacted for further information on projects in identified areas and a copy of the Departmental research and postdoctoral prospectus.

Department of Pharmaceutical Sciences
Aston University
Aston Triangle
Birmingham B4 7ET (6287)F

UNIVERSITY OF SURREY
DEPARTMENT OF CHEMISTRY
STUDENTSHIPS

Applications are invited from Chemistry graduates, or those about to graduate, for the following research studentships which will become available as from 1st October, 1985

1. Two University of Surrey sponsored research studentships to work with Professor J M Pratt in the general area of Bio-inorganic Chemistry.

2. An internal departmental studentship to work on the Structure Determination of High Valent Porphyrin Complexes Related to the Peroxidases and Cytochrome P-450. (Drs K B Nolan and D C Povey).

3. A Ministry of Agriculture, Fisheries and Food sponsored studentship to study the Effects of Phytate on Mineral Bioavailability and Heavy Metal Contaminants. (Dr K B Nolan).

4. A CASE studentship in conjunction with ICI Pharmaceuticals to study A Thermodynamically-Based Scale of Hydrogen Bond Basicities. (Dr M H Abraham).

5. A CASE studentship in conjunction with the Imperial Cancer Research Fund to study Aromatic Hydroxylations. (Dr J R Jones).

6. A Ministry of Defence sponsored studentship to study Aromatic Amine Cure of Epoxy Resins. (Drs G J Buist and J R Jones).

Interested persons should send their curriculum vitae and names and addresses of two referees to Dr J R Jones, Chemistry Department, University of Surrey, Guildford, GU2 5HX as soon as possible. (6261)F

UNIVERSITY OF LIVERPOOL
DEPARMENT OF BOTANY
RESEARCH STUDENTSHIPS

The following research studentships are available within the Department of Botany tenable from October 1st, 1985.

NERC Nitrogen economy of wood-decay Basidiomycetes (Professor D H Jennings).

The role of mutation in the origin of metal tolerance (Professor A D Bradshaw, Dr T McNeilly and Dr H A Collin).

Dynamics of annual plant communities (Dr A M Mortimer and Dr P D Putwain).

SERC The theoretical and practical significance of plasmid transfer between streptomycetes. (Dr S T Williams, Professor D A Ritchie and Dr A M Mortimer).

SERC/CASE Ion transport in the fungus Dendryohiella salina (Professor D H Jennings).

Further details of these studentships are available from Professor A D Bradshaw, Department of Botany.

Applicants should have or be expecting at least a 2:1 Honours Degree in an appropriate biological subject. The Department of Botany has a very active research school with excellent facilities, concerned with pure and applied aspects of botany.

Applications should be made as soon as possible and at least by June 3rd to The Registrar, The University, PO Box 147, Liverpool L69 3BX. They should include details of academic experience and the names of two referees. Quote Ref: RV/255/N. (6288)F

UNIVERSITY OF ST ANDREWS
DEPARTMENT OF BIOCHEMISTRY AND MICROBIOLOGY
SERC CASE RESEARCH STUDENTSHIPS

Applications are invited for the above from undergraduate students who expect to obtain at least an upper second class honours degree in biophysics, biochemistry, microbiology, genetics, botany or related subjects. Biotechnology research projects, involving collaboration between an academic staff member and an individual partner, in:

(1) Cloning of the nitrate reductase structural gene of barley in collaboration with Long Ashton Research Station (Dr J L Wray)

(2) Biochemical and genetic studies of the mushroom Pleurotus in collaboration with Mitchell Mushrooms (Dr W M Ledingham)

(3) An investigation into the interrelationships of the cell wall properties of Thiobacillus ferrooxidans and bioleaching processes of ferrous iron and sulphide oxidation in pyritic ores in collaboration with Shell (UK) PLC (Dr W J Ingledew).

For further information, contact the staff member concerned.

Applications, naming at least two referees and stating the project(s) of interest to The Secretary, Department of Biochemistry, University of St Andrews, St Andrews, Fife KY16 9AL. Telephone enquiries to 0334-76161 ext 295. (6298)F

QUEEN MARY COLLEGE
(University of London)
School of Biological Sciences
SERC-CASE STUDENTSHIP

An SERC-CASE Studentship in collaboration with the Biological Evaluation Division, Shell Research Ltd., is available to investigate host plant selection and feeding behaviour in the rice brown plant hopper, Nilaparvata lugens. The project will include the development of new techniques for monitoring food uptake and for assessing the role of different classes of sensory receptor in the regulation of settling and feeding in this and in other small leaf and plant hopper pests of rice. An important part of the investigation will be to examine the way in which motility and feeding behaviour may be affected by a novel class of insecticide both in individual hoppers and in populations of N lugens exposed to sublethal doses.

Applicants should have or expect to obtain a first or upper second class honours degree and will be expected to register for a PhD degree. Applications, together with a cv and the names of two academic referees, should be sent to Dr L J Goodman, School of Biological Sciences, Queen Mary College, Mile End Road, London E1 4NS as soon as possible. Further details can be obtained from the above address. (6295)F

INSTITUTE OF AQUACULTURE
UNIVERSITY OF STIRLIN
Applications are invited for a
NERC-FUNDED STUDENTSHIP

in the following areas: The toxicity aluminium to Atlantic Salmon Acidic Waters or Quantitative a Qualitative Aspects of Filter-Feedi on cyanobacteria by Fish.

Further details on these proje and application forms may obtained from the Academ Administrator, the Institute Aquaculture, University of Stirlir Stirling FK9 4LA, Scotland. (6305)F

ST. MARY'S HOSPITAL MEDICAL SCHOOL
(University of London)
Norfolk Place, London W21 1PG
SERC CASE STUDENTSHIP

Applications are invited for a SER Case Studentship in collaborati with Shell Research Ltd (Dr D H Hi son) for research (leading to a Ph degree) into the effect of environme tal conditions on the metabolism chemicals by fish.

Applicants should have, or expe to obtain, a first or second cla honours degree in biochemistry chemistry, and have an interest chemical and environment toxicology.

Applications, including the nam of two referees should be sent as so as possible to Dr P Millburn, Depa ment of Biochemistry, at above a dress, from whom further particula may be obtained (tel 01-723-12 ext 118). (6277)F

FELLOWSHIPS

UNIVERSITY COLLEGE CARDIFF
DEPARTMENT OF BIOCHEMISTR
POST-DOCTORAL FELLOWSHIP

A Post-doctoral Fellowship fund by the Cystic Fibrosis Research Tru is available to work on alginate bi synthesis in mucoid strains Pseudomonas aeruginosa, under t direction of Drs P Gacesa and N Russell. Candidates having a PhD the field of biochemistry/micr biology, particularly those wi experience in enzymology or NM are invited to apply.

The appointment is for 3 yea subject to annual renewal, and t salary will be £7,520 in the first ye (RA 1A scale, under review). Duti to commence September, 1985.

Applications (2 copies) including curriculum vitae, together with t names and addresses of two referee should be forwarded to t Establishment Officer, Universi College, PO Box 78, Cardiff C 1XL. Closing date 23rd May, 198 Ref: 2952. (6307)E

FELLOWSHIPS continued

MAX-PLANCK-INSTITUTE FOR BIOPHYSICS
Postdoctoral Research Fellowship in

BIOPHYSICS

Characterization of polydisperse lipid systems by photon correlation spectroscopy.

Applications are invited from candidates interested in joining a multi-disciplinary research group studying transport processes in membranes. The fellowship is offered for a one to two year period starting May 1985 or later. Salary will be from DM 26.000 to DM 32.000 p.a., net, depending on experience.

Send application (c.v., list of publications, names of two referees) to Dr. E. Grell, Max-Planck-Institute for Biophysics, Heinrich-Hoffmann-Str. 7,6000 Frankfurt 71, (West Germany). (W1826)E

UNIVERSITY OF LEICESTER
DEPARTMENT OF PHARMACOLOGY AND THERAPEUTICS
MERCK SHARP & DOHME NEUROSCIENCE RESEARCH FELLOWSHIP

Applications are invited for a MSD Neuroscience Research Fellowship to study cholinergic receptor-effector mechanisms in brain. The project involves receptor labelling and an assessment of receptor-effector coupling by examination of cyclic nucleotide and inositol phospholipid metabolism in brain. Applicants should have, or shortly expect to have, a PhD and possess suitable experience in pharmacology/biochemistry/neurobiology. Some experience of discrete cerebral lesioning or tissue culture would be an advantage. Although this position is with Professor S R Nahorski's research group in Leicester, it is possible that a short period may be spent at the MSD Neuroscience Research Centre, Harlow, with Dr L L Iversen. The Fellowship is from 1st October 1985, or nearest conveient date, and is for a period of one year in the first instance and for which funding may be extended for a further two years.

Salary is on the scale £7,520 -£12,150 (Research 1A).

Additional information can be obtained from Professor S R Naborski, Department of Pharmacology and Therapeutics, Medical Sciences Building, University of Leicester, University Road, Leicester, LE1 7RH, UK, (0533-551234, Ext 361) to whom applications, including CV and names of two referees, should be sent. (6306)E

UNIVERSITY OF BRISTOL
DEPARTMENT OF ZOOLOGY
POSTDOCTORAL POSITION IN MOLECULAR BIOLOGY)
(Neurobiology)

Applications are invited for a three-year fellowship to investigate the regulation of expression of multi-functional genes in the mammalian nervous system implicated in the regulation of cellular differentiation and neuromuscular synapse formation. The project will be funded by the Wellcome Trust.

The successful applicant will hold a PhD in Biochemistry/Molecular Genetics or a related field, and have experience in DNA manipulation and hybridisation techniques with a record of research into any aspect of the control of transcription in eukaryotic cells.

Laboratory facilities will be provided in the newly-established Molecular Genetics Unit at Bristol.

An appointment will be made on the University Academic Staff Range IA at a starting salary of £7520-£9390 per annum.

Initial enquiries may be made to Dr L W Haynes, Department of Zoology, The University of Bristol, Woodlands Road, Bristol BS8 1UG (0272 24161 ext 57), to whom applications, accompanied by cv and the names of three referees should be addressed before 24 May. (6116)E

POSTDOCTORAL FELLOWSHIP
in the area of
Immunological control of Membrane Transport
Primary responsibility:

production and study of monoclonal antibodies to membrane transport proteins. Position available July 1, 1985, one year renewable, salary competitive.
Send curriculum vitae and names of three referees to Dr. Philip Dunham, Department of Biology, Syracuse University, Syracuse, New York 13210. Equal opportunity employer. (NW1724)E

1985 — 1986
L.S.B. Leakey Foundation
RESEARCH FELLOWSHIP
FIELD STUDIES OF THE GREAT APES

The fellowship will be awarded to an individual to facilitate the establishment of a long-term research project on a wild population of great apes. Preference will be given to studies with significance for understanding human origins and to those which explore the causes of variation in ape behaviour, particularly in previously unstudied habitats. The fellowship, worth up to $20,000, is for field expenses only

Applicants should submit curriculum vitae and a one-page statement of research goals by 1 May 1985 to: The L.S.B. Leakey Foundation, Attention: Kathleen F. Galvin, Grants Officer, Foundation Center, Pasadena, Calif. 91125. Eligible candidates will be asked to provide further details by 15 June 1985. The recipient will be announced in October 1985. (NW1717)E

CONTINENTAL EUROPEAN FELLOWSHIP AWARDS 1986–87 FOR ACADEMIC STAFF

Applications are invited for awards by the CIBA-GEIGY Fellowship Trust for the academic year 1986/87

Senior CIBA-GEIGY Fellowships

Senior CIBA-GEIGY Fellowships will be awarded to start from an agreed date during the academic year 1986/87 These will be available to lecturers, senior lecturers or readers who hold, and will return to, permanent teaching positions at United Kingdom or Republic of Ireland universities, polytechnics or comparable teaching institutions, who wish to undertake research at an agreed continental European university or technological university These posts should have been held for a period of at least five years in the field of chemistry, biochemistry, chemical technology, chemical engineering and biology, particularly in its relation to chemistry.

Awards are made for a period of six to twelve months

Value of the awards £10,000 per annum plus travelling expenses

CIBA-GEIGY Fellowship awards are intended to supplement Fellows' salaries for the period of tenure

Further details and application forms, are obtainable from: The Secretary, The CIBA-GEIGY Fellowship Trust, 30 Buckingham Gate, London SW1E 6LH (Telephone 01-828 5676).

The closing date for applications is 1 November 1985

CIBA–GEIGY

(6248)E

UNIVERSITY OF WESTERN ONTARIO
Department of Obstetrics and Gynaecology

POSTDOCTORAL FELLOWSHIP

Funds are immediately available for two postdoctoral scientists to work within the newly established Gynaecology Cancer Research Laboratory at Victoria Hospital. The principal interests with this laboratory focus on reproductive endocrinology and the identification of tumour markers. One of the projects for which funds have been obtained will initially involve sequencing of cloned cDNAs for two human plasma steroid binding proteins and studies of the hormonal regulation of their synthesis by cells in culture. A second project will largely involve the isolation of mRNA from human ovarian tissue and the construction and analysis of cDNA libraries with the ultimate objective of identifying one or more specific ovarian tumour marker proteins.

Candidates should hold a Ph.D. in Biochemistry or Molecular Biology and be familiar with the principles and practical aspects of recombinant DNA technology. Applications, including a curriculum vitae, should be addressed to:

Dr. Geoffrey L. Hammond
The University of Western Ontario
Gynaecology & Cancer Research Laboratory
375 South Street London, Ontario. N6A 4G5.

In accordance with Canadian Immigration requirements, this advertisement is directed to Canadian citizens and permanent residents.

(NW1711)E

INDIANA UNIVERSITY

NEW PERSPECTIVES ON NUCLEIC ACIDS

A SYMPOSIUM

September 29 — October 2, 1985
Presented by the
Institute of Molecular and Cellular Biology
at Indiana University
Bloomington, Indiana

This Symposium will address recent developments in the structure and function of polynucleotides. Session speakers, leaders in their fields, will provide broad coverage of topics of interest to workers in both academic and biotechnology settings.

Program topics will include: physical techniques in determination of polynucleotide structure, role of higher order structures in RNA function, RNA-protein interactions, RNA processing, RNA roles in regulation of translation, transport and replication.

Session speakers include:

John Abelson	Judith McClarin	Brian Reid
Struther Arnott	Donald Mills	Phil Sharp
Andrea Branch	Peter Moore	Joan Steitz
Tom Cech	Harry Noller	Olke Uhlenbeck
Larry Gold	Norman Pace	Peter Walter
Christine Guthrie	Dinshaw Patel	Carl Woese
Michael Mathews	Barry Polisky	Michael Yarus

Sponsored in part by the Indiana Corporation for Science & Technology, Abbott Laboratories, Boehringer Mannheim Biochemicals, Boehringer Mannheim Diagnostics, Inc., Eli Lilly & Company, International Minerals and Chemical Corporation, and Monsanto Company.

For information and application write to: Director, Institute for Molecular and Cellular Biology, Jordan Hall 322A, Indiana University, Bloomington, Indiana 47405. (NW1707)M

LEUKAEMIA RESEARCH FUND

International Research Symposium on
"GROWTH FACTORS, HAEMOPOIESIS AND MALIGNANCY"
at Royal College of Physicians, London NW1
on WEDNESDAY 29TH MAY 1985
Registration Fee (including lunch) £15.
For programme details and registration form apply to:
LEUKAEMIA RESEARCH FUND,43 Great Ormond Street, London WC1N 3JJ, (tel: 01-405 0101) (6100)M

CIBA FOUNDATION SYMPOSIUM BURSARY SCHEME

AIM: To enable young scientists to attend Ciba Foundation symposia and subsequently spend 4 weeks in the laboratory of one of the symposium participants.

The bursary will cover —
a) travel expenses
b) board and lodging for the duration of the bursary

Qualifications: Applicants must be aged between 25-35 years on the closing date for application, and actively engaged in research on the topic covered by the symposium of their choice.

Topics:
1 FUNCTIONS OF THE PROTEOGLYCANS
2 THE JUNCTIONAL COMPLEXES OF EPITHELIAL CELLS
3 MECHANISM OF DEATH OF NERVE CELLS
4 AUTOIMMUNITY AND AUTOIMMUNE DISEASE

Applications: In writing, addressed to:
Mrs S Venables, The Ciba Foundation, 41 Portland Place, London W1N 4BN including the following information.
a) Full name, address and date of birth
b) Symposium of choice (one from the above list)
c) Qualifications and short résumé of further education
d) Career history, including full list of publications
e) Details of current research and aims of future career
f) Names and addresses of two referees

Closing Date for Applications: 30 September 1985. (6293)M

CONFERENCES and COURSES

UNIVERSITY OF DURHAM

DEPARTMENT OF BOTANY

MSc BIOTECHNOLOGY

This new one-year course (starting 27 September 1985) results from collaboration between the Department of Botany and Imperial Chemical Industries PLC. The course, which combines lectures and practicals with a research project, will provide an overview of modern concepts and techniques in biotechnology Topics include: techniques in molecular biology and cell biology; genetic engineering and eukaryotes; tissue culture and monoclonal antibodies; industrial microbiology; fermentation and chemical engineering; microbial leaching and metal stripping; enhanced oil recovery and degradation air and microorganisms; biomass conversion; novel plant products; legal and regulatory aspects.

Instruction will include a significant contribution from ICI staff, especially from Biological Products Business at Billingham. The course is especially suitable for biological chemists, microbiologists, botanists and applicants from related disciplines, and will also offer a rapid and efficient retraining programme for applicants seconded from industry.

Application forms and further particulars may be obtained from Dr B A Whitton, MSc Biotechnology, University of Durham, Durham DH1 3LE, England. (6266)C

UNIVERSITY OF LEICESTE

SCHOOL OF BIOLOGICAL SCIENCES

DEPARTMENT OF BOTANY

BIOTECHNOLOGY SHORT COURSE CO-ORDINATOR

Applications are invited for the po of Biotechnology Short Course C ordinator from those with curre research interests in the field of pla biotechnology. This post has lectur status. The person appointed w assess the demand for pos experience courses in biotechnolo and subsequently in other areas biotechnology. He or she will expected to pursue a researc programme within the Departme of Botany.

This appointment will be for fi years, supported by a grant from t DES under its PICKUP programm

Initial salary will depend qualifications and experience on t scale £7,520 to £14,925 (und review).

Further particulars ar application forms can be obtain from the Registrar, University Leicester University Road, Leiceste LE1 7RH, to whom applicatio should be returned by May 1985. (6280)C

IMPERIAL COLLEGE

DEPARTMENT OF CHEMICAL ENGINEERING AND CHEMICAL TECHNOLOGY

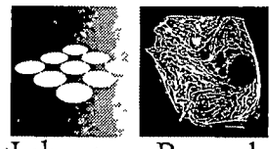
POST-EXPERIENCE COURSE

A post-experience course on "Par cle Sizing and Characterisation Light Scattering" will be given 4th-5th July 1985.

For further information contact A R Jones, Department of Chemic Engineering and Chemical Tec nology, Imperial College, Lond SW7 2BY. (6246)

KING'S COLLEGE LONDO (KQC)

University of London



MSc DEGREE IN GENERAL BIOCHEMISTRY

Both part-time and full-time cours will commence in October 1985 a will be held at the Campden Hill Sit Kensington. The part-time cour extends over two academic years a involves attendance for one aft noon and one evening per week. T full-time course extends over o academic year and involves research project.

Qualifications. Candidates shou normally hold a first or second cl honours degree (or an approv equivalent qualification) in a scien subject. Graduates in Medicin Dentistry or Veterinary Medicine also admitted. The course is appropriate to recent graduates fro honours Biochemistry courses.

For further information and app cation forms write, in the fi instance to the Secretary, Bi chemistry Department, Chels College, Manresa Road, Lond SW3 6LX. (6304)C

Labsystems Research Symposium

Synthetic Peptides in Biology and Medicine June 6–8, 1985 Hotel Aulanko, Hämeenlinna, Finland

Labsystems has initiated a series of biannual research symposia to molecular biology. The theme of the first meeting will be "Synthetic Peptides in Biology and Medicine".

Topics include:

Protein structure and the basis for peptide synthesis
Immunology of synthetic peptides
Synthetic peptides in microbiology
Synthetic peptides in cell biology
Peptide hormones

The proceedings will be published.

Invited speakers will include F. Audibert (France), E. Beachey (USA), J. De Larco (USA), R. Eisenman (USA), G. Evan (UK), T. Hopp (USA), H. Jornvall (Sweden), S. Kent (USA), V. Marchesi (USA), R. Neurath (USA), S. Oroszlan (USA), M. van Regenmortel (France), E. Ruoslahti (USA), J. Schlessinger (Israel), G. Schild (UK), G. Terenghi (UK), L. Terenius (Sweden), G. Walter (USA) and E. Wimmer (USA).

The registration fee is 750 FIM, which will cover accommodation and meals. Participants are expected to pay their own travel expenses.

Applications should be sent to: Organizing Committee, Labsystems Research Symposium, P.O. Box 8, 00881 Helsinki, Finland, Telex 121949 Labsy sf, not later than April 30, 1985. They should contain a curriculum vitae, including the applicants scientific background and research interests.

The Organizing Committee

Kari Alitalo, Jorma Keski-Oja, Veli-Pekka Lehto, Ale Närvänen, Paul Partanen, Ralf Pettersson, Jukka Suni, Antti Vaheri.

(W1831)M

CONFERENCES and COURSES continued

1985 COLD SPRING HARBOR CONFERENCE ON CANCER CELLS

DNA Tumor Viruses: Control of Gene Expression & Replication
Wednesday, September 4 — Sunday, September 8, 1985

Organized By

TERRI GRODZICKER, Cold Spring Harbor Laboratory
PHILLIP SHARP, Massachusetts Institute of Technology
MICHAEL BOTCHAN, University of California, Berkeley

The 1985 Cold Spring Harbor Conference on Cancer Cells entitled, "DNA Tumor Viruses: Control of Gene Expression and Replication" will be held from Wednesday, September 4, through Sunday, September 8, 1985. We anticipate a schedule with approximately fifty major speakers who will present talks of 20-25 minutes with ample time for discussion.

The meeting will be devoted to a broad discussion of aspects of genetic regulation using SV40, polyoma virus, adenoviruses, papilloma viruses and herpes viruses as model systems. Planned session include:

Control of transcription: enhancers and promoters
Control of transcription: regulatory proteins
In vitro approaches to transcription
Regulation of RNA processing and translation
DNA replication and recombination
Transforming proteins
Stages of Transformation

Requests for registration material should be directed to the Meetings Coordinator, **Cold Spring Harbor Laboratory,** P.O. Box 100, Cold Spring Harbor, NY 11724.

(NW1712)C

ETTORE MAJORANA CENTRE FOR SCIENTIFIC CULTURE

International School of Biophysics

14th Course: GENERATION OF DIVERSITY AND SPECIFICITY IN THE NERVOUS SYSTEM

Erice-Trapani-Sicily: 14-24 July 1985

Invited speakers include: C. Barnstable (USA), G. Berlucchi (Italy), P. Calissano (Italy), A. Cattaneo (Italy), J.P. Changeux (France), U. Di Porzio (Italy), A. Gorio (Italy), N.M. Le Douarin (France), G. Levi (Italy), R. Levi-Montalcini (Italy), J. Mallet (France), R. Miledi (USA), R.J. Milner (USA), J.G. Nicholls (Switzerland), P. Rakic (USA), U. Rutishauser (USA), J. Szentagothai (Hungary), D. Trisler (USA), B. Zipser (USA).

Topics include: Monoclonal antibodies and neuronal specificity; recombinant DNA approaches to nerve cell function; epigenetic factors in neuronal development; molecular system for cell recognition; neurotransmitter receptors; nerve cell lines and primary cultures; neurite generation and regeneration; synaptic plasticity; neuronal organization and brain function.

Application: Closing date for application is **15th June, 1985.** No special application form is required. Applicants should specify: i) date and place of birth, together with their present nationality; ii) degree and other academic qualifications; iii) list of publications; iv) present position and place of work. Young persons with limited experience should enclose a letter of recommendation from the head of their research group or from a senior person active in the field. The total fee including full board and lodging (arranged by the School), is US $600. Thanks to the generosity of the sponsoring Institutions, partial support may be given to deserving students who need financial help. This must be specified and justified in the application letter.

Application to: Dr. G. Boera, Institute of Cell Biology CNR, Via Romagnosi 18A, 00196 Rome, Italy. Tel. 6/3611407. Telex 622195 INGENR I, Telefax 3609402.

'M.G.F. Fuortes' Scholarships: Two 'M.G.F. Fuortes' Scholarships will be awarded to deserving neurobiologists one by the 'M.G.F. Fuortes Memorial Fund' (reserved for a USA applicant), and the other by the 'Ettore Majorana Centre'. The scholarships will cover both travel expenses and school fees. The letter of application for these scholarships should be sent, together with a duplcate of the application for these scholarships should be sent, together with a duplicate of the application for the attendance to the Course to: **MGF Fuortes Memorial Fund, Laboratory of Neurophysiology, NIH Bldg, 36 Room 2C-02, Bethesda, Md.20205, USA.**

R. Levi-Montalcini, P. Calissano Direcots of the Course. A. Borsellino Director of the School. A. Zichichi Director of the Centre. (W1830)C

AWARDS

DEPARTMENT OF HUMAN ANATOMY, OXFORD
MRC BRAIN METABOLISM UNIT, EDINBURGH

MEDICAL RESEARCH COUNCIL PARTNERSHIP TRAINING AWARD

Applications are invited from final year students expecting to graduate with a first or upper second class honours degree in appropriate branches of science, medicine or veterinary medicine for a 'partnership Training Award'. The successful applicant will study the metabolism of and the development of neural connections and neurotransmitter receptors in hypothalamic grafts in hypogonadal mice, a mutant strain totally deficient in hypothalamic luteinizing hormone releasing hormone It is expected that this research will lead towards the degree of either D.Phil. (University of Oxford) or PhD (University of Edinburgh)

Applications including a full curriculum vitae together with the names of 2 professional referees should be addressed to either Dr. H. M. Charlton, Department of Human Anatomy, South Parks Road, Oxford OX1 3QX. or Professor G. Fink, MRC Brain Metabolism Unit, University Department of Pharmacology, 1 George Square, Edinburgh EH8 9JZ not later than May 20th, 1985. (6204)N

THIRD MEADOW BROOK CONFERENCE ON MOLECULAR MECHANISM OF STEROID HORMONE ACTION SEPTEMBER 15-18, 1985

The Conference will address recent developments in steroid hormone action and will be held at the Meadow Brook Mansion of Oakland University. Invited speakers include:

W. Bardin, J. Baxter, M. Beato, J. Clark, J. Gorski, G. Greene, J. Gustafsson, M. Haussler, K. Horwitz, O. Janne, S. Liao, E. Milgrom, G. Mueller, B. O'Malley, J. Oppenheimer, G. Ringold, A. Roy, W. Schrader, T. Spelsberg and J. Tata.

For additional information concerning registration and poster presentation contact:

Dr. F.H. Sarkar, Conference Coordinator
Department of Biological Sciences
Oakland University
Rochester, MI 48063

CONVENIENT·INFORMATIVE·TIMELY·PROVOCATIVE

FOUR DYNAMITE REASONS WHY YOU SHOULD SUBSCRIBE TO BIO/TECHNOLOGY NOW . . .

1. You'll save time. Because you don't have time to read every journal in the field, BIO/TECHNOLOGY is written and edited to give you all the information you need in ONE convenient source. BIO/TECHNOLOGY is the only journal to give you news. Features. Original research. Product evaluations. Industrial applications. Job openings. Book and product reviews. And more. If it's important to your work, you'll find it between the covers of BIO/TECHNOLOGY.

2. You'll learn new ways to improve your on-the-job skills and run a more successful operation. Each month BIO/TECHNOLOGY gives you the scoop on invaluable start-up information . . . the latest instrumentation . . . marketing breakthroughs . . . funding sources . . . new technologies . . . patents and licences . . . profiles on how others are avoiding the pitfalls and reaping the rewards. In fact, just one practical tip from BIO/TECHNOLOGY can be worth many times the cost of your subscription.

3. You'll be up-to-date on all major industry developments. With correspondents all over the world, BIO/TECHNOLOGY delivers the inside story on who's doing what, where. You'll get the latest word on changing government regulations and tax law, and how they affect your work.

Plus you'll read original research papers by bench scientists, engineers, and biologists that will help keep you in the forefront of every new discovery worth knowing about.

4. You'll get new ideas you can put to use immediately. BIO/TECHNOLOGY lets you rub elbows with eminent scientists, tour new facilities and learn how new processes work in every field from genetic engineering to molecular biology. Each month, BIO/TECHNOLOGY helps spark ideas for your own research, for new industrial applications and for getting along in the increasingly competitive financial arena.

If you're not already subscribing to BIO/TECHNOLOGY, don't delay the moment any longer - return the coupon below and we will send you twelve issues. You risk nothing. If for any reason BIO/TECHNOLOGY doesn't live up to your highest expectations, just let us know and you'll receive a full refund on all unmailed copies. Remember too, that your subscription may be tax deductible.

TO START RECEIVING YOUR SUBSCRIPTION, FILL OUT THE COUPON BELOW AND RETURN WITH PAYMENT TO:

U.S.A.: BIO/TECHNOLOGY
Subscription Order Dept., P.O. Box 316
Martinsville, New Jersey 08836 U.S.A.

To speed up your subscription in the U.S.A., call toll free 1-800-524-0328.

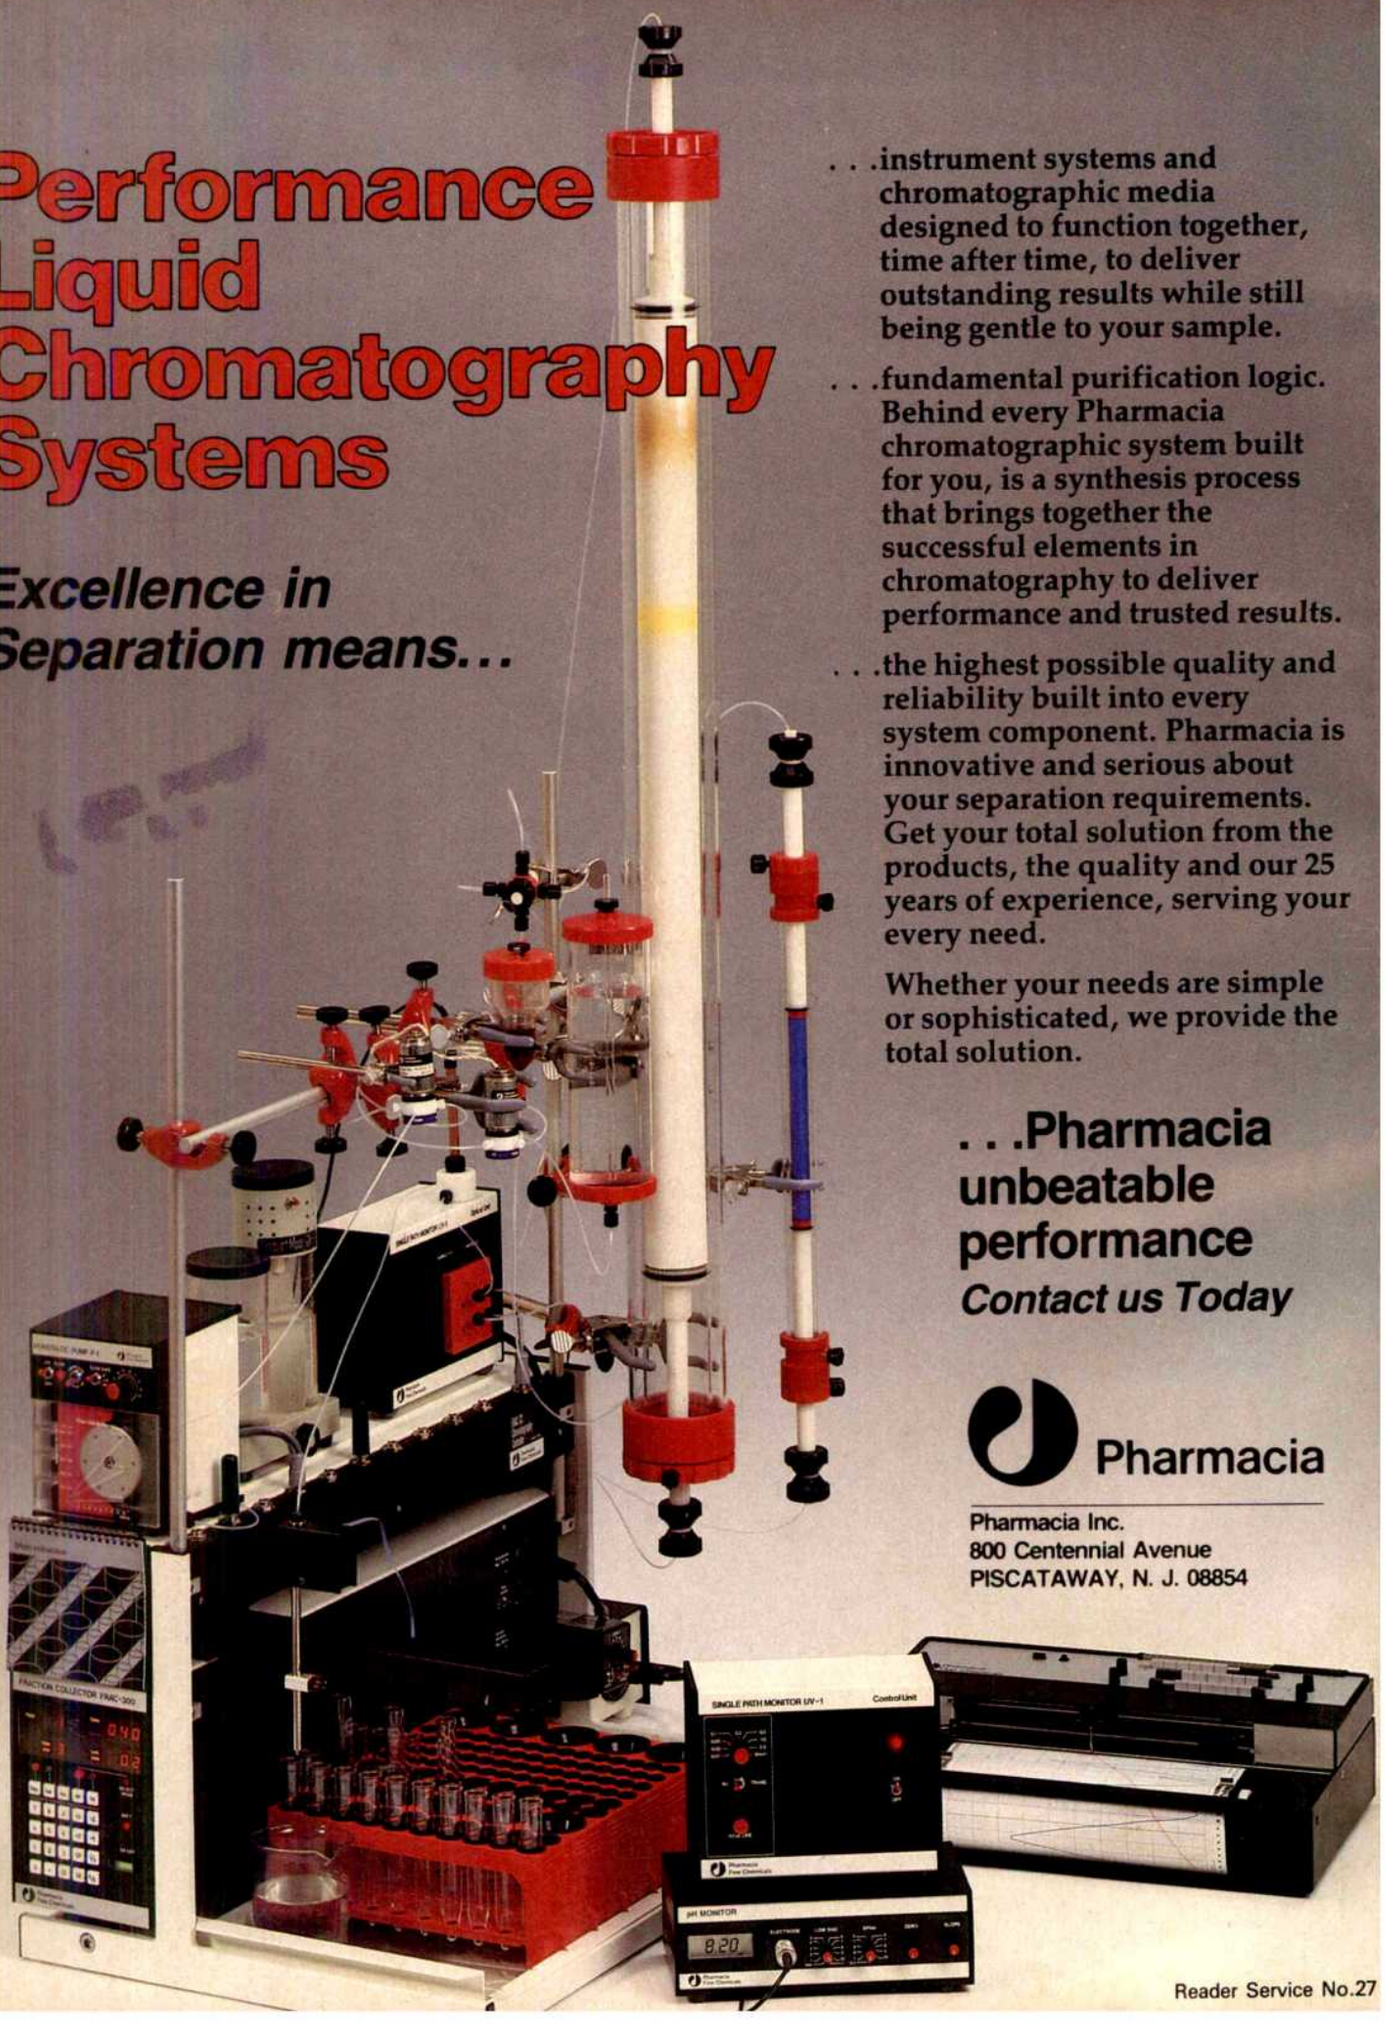
Performance Liquid Chromatography Systems

Excellence in Separation means...

. . .instrument systems and chromatographic media designed to function together, time after time, to deliver outstanding results while still being gentle to your sample.

. . .fundamental purification logic. Behind every Pharmacia chromatographic system built for you, is a synthesis process that brings together the successful elements in chromatography to deliver performance and trusted results.

. . .the highest possible quality and reliability built into every system component. Pharmacia is innovative and serious about your separation requirements. Get your total solution from the products, the quality and our 25 years of experience, serving your every need.



Whether your needs are simple or sophisticated, we provide the total solution.

. . .Pharmacia unbeatable performance

The new LKB Quality Chemicals Catalogue

Hot off the presses is a new 76-page, full-color catalogue—the LKB Quality Chemicals Catalogue. This latest edition packs comprehensive, up-to-date information on all the reagents, buffers, separation media and other supplies available from LKB. It also provides more information about each product, more applications and complete information on several new products such as preparative-scale chromatography columns, new HPLC columns, and amino acid analysis buffers and reagents.

If your lab does electrophoresis, electrofocusing, chromatography, HPLC, luminescence, liquid scintillation counting, amino acid analysis or cellular biology, you can't afford to be without it. Offering complete descriptions of the nearly 400 fine chemicals and consumables in our range, it's your mail-order reference to the single-source supplier. Ask for your free copy today.

PEPTIDE ANTISERA

CRB has considerable experience in the preparation, purification and conjugation of synthetic peptides for use in the preparation of antipeptide antibodies.

To complement our range of biologically active peptides CRB offers:

POLYCLONAL PEPTIDE ANTISERA

Fully characterised for radioimmunoassay

Antisera raised to

ANP
Calcitonin
CGRP
CCK
Gastrin
Glucagon
Neurotensin
Oxytocin
Secretin
Substance P
Arg-Vasopressin
Bombesin
Katacalcin
CRF
Leu-Enkephalin*
GIP
Motilin
NPY
PHI
Somatostatin
VIP

Designed for and tested by immunocytochemical techniques

Antisera raised to

Bombesin
CCK-39
Met-Enkephalin
GIP
Motilin
Neurotensin
Somatostatin 14
Substance P
CCK-8
Leu-Enkephalin
FMRF-amide
Glucagon
NPY
PHI
Somatostatin 28
VIP

*A new antiserum for the specific measurement of Total Enkephalins and/or Leu-Enkephalin and/or Met-Enkephalin. The antigen has been prepared by a new methodology resulting in a conjugate of Leu-Enkephalin with BSA via 4'-position of enkephalin residue 1 (see Morley **et al.** Neuropeptides **4**, 377 (1984))

Each product is supplied with a data sheet giving information on specificity and recommended assay protocol and staining procedures for radioimmunoassay and immunocytochemistry respectively.

For further information please ask for our Peptide Antisera 1985/86 Catalogue which gives details of the complete range.

RQ1™ DNase

Promega's RQ1 DNase performs in the most stringent RNA applications ... and we prove it

■

Our RQ1™ DNase arrives pre-tested, qualified and ready to use for all applications of RNase-free DNase, including Northern blots and digestion of DNA in Riboprobe™ System transcription reactions.

■

Our RQ1 DNase does not degrade RNA, and its performance is verifiable. We provide you with a positive control DNA/RNA mixture which allows you to ensure yourself that RQ1 DNase is suitable for your application.

An experiment with our positive control reaction mixture is shown above. This mixture consists of a fragment of pBR 322 plasmid DNA cloned into the polylinker of the Riboprobe™ System pSP 64 transcription plasmid. This DNA construction is then linearized and transcribed with Riboprobe polymerase to generate a discrete, single-stranded RNA species complementary to a portion of the pBR 322 fragment. Lane 1, DNA template; Lane 2, transcription reaction; Lane 3, transcription reaction followed by RNase A treatment to distinguish RNA from DNA on the gel; Lane 4, transcription reaction followed by normal digestion with RQ1 DNase; Lane 5, transcription reaction followed by 100 fold overdigestion with RQ1 DNase.

■

Promega's RQ1 DNase is provided in an easy-to-use configuration.

As a convenience to you our RQ1 DNase comes in a buffered glycerol solution. It requires no reconstitution or dilution prior to use. Simply pipette the appropriate amount of RQ1 DNase into your reaction and incubate.

Also, we define RQ1 DNase in a functional assay which directly relates to your use. Thus, we tell you the amount of RQ1 DNase required to digest a given amount of DNA to completion. You no longer have to guess at the number of units to add.

■

Performance is guaranteed.

We guarantee that when you use our RQ1 DNase with our positive control reaction mixture you will obtain equivalent or better results than those shown on the left. If there is any question regarding your results we will automatically replace the product, credit your account or make arrangements for a refund, at your discretion.

■

Complete applications protocols are available.

A full product description with technical protocols for use is available from Promega Biotec, along with complete details on the experiment shown. Contact us or one of our full service distributors or subsidiaries shown below.

RQ1™ DNase

Functionally proven, RNA compatible Deoxyribonuclease I

Promega Biotec

Hybond™ the choice in blotting membranes

Hybond™ membranes are the ideal transfer membranes for nucleic acid and protein blotting, offering:

- **Flexibility** – choose nylon or nitrocellulose
- **Convenience** – a wide variety of shapes and sizes
- **Optimum performance** – supported by comprehensive protocols
- **Compatibility** – rigorous applications testing ensures compatibility with our extensive range of blotting products

As you would expect from Amersham,
Hybond membranes are subjected to our usual quality assurance programmes.

Hybond-N Nylon
Hybond-C Nitrocellulose

NATURE VOL. 315 9 MAY 1985

COVER

An area of lichen/black spruce woodland near Bush Lake in Quebec, Canada. A tree-ring chronology has been constructed for this woodland for the years 1398 to 1982, giving some pointers to conditions during the Little Ice Age and providing the longest tree-ring chronology yet available for eastern North America. (See page 135)

Hot on delivery...

...cold on arrival

When you order molecular biologicals from Pharmacia you'll find we're pretty hot on delivery.

We'll dispatch your order as soon as we get it, packing it carefully in wet or dry ice.

Now our enzymes are supplied in screw cap mini vials with new waterproof labels, and will easily fit into your centrifuge tubes and freezer trays.

At Pharmacia Molecular Biology Division that's all part of the service. We realize that the success of an experiment depends on the quality of the products used and the speed at which you get them. With us you'll find that the only thing kept on ice is your product - not your experiment.

Contact us today and we'll send you our free catalogue with details of over 800 molecular biologicals.

Pharmacia... your partner in molecular biology.

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

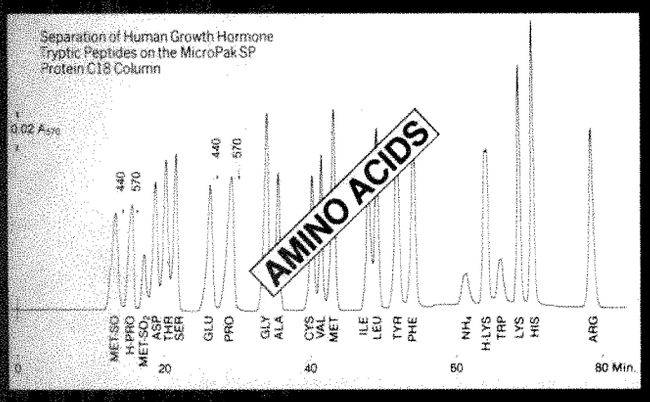
Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

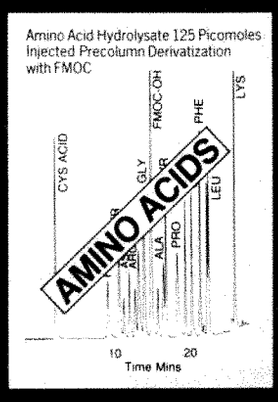
Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

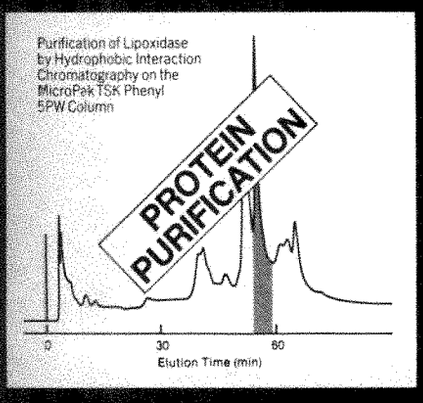
Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.



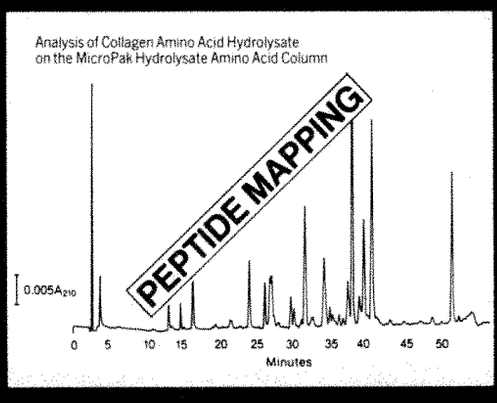
References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.



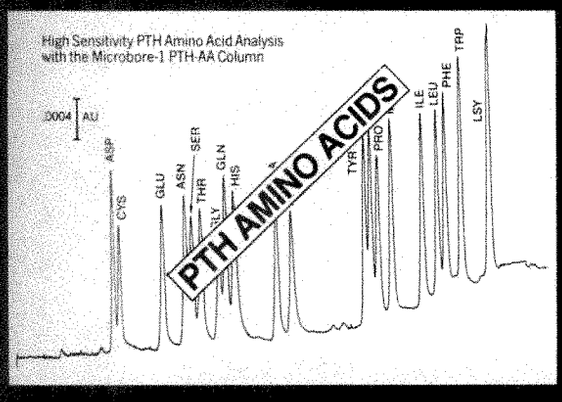
Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.



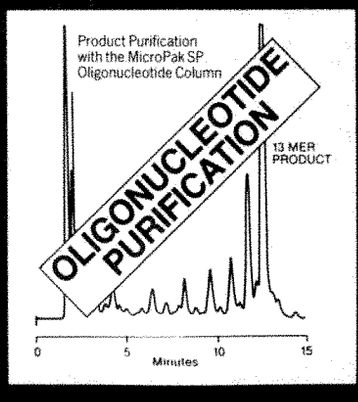
Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*



Biopolymer problems?



No problem with Varian HPLC.



Post-Column Derivatization
Hydrolysate and physiological fluid analysis. Ninhydrin and OPA chemistries. Fully automated systems for dedicated amino ac analysis.

Pre-Column Derivatization
Rapid analysis. Subpicomole sensitivity. Sta derivatives. Simultaneous analysis of prima and secondary amino acids.

Protein Purification
Full spectrum of MicroPak™ TSK size excl ion exchange, reversed phase, and hydrop interaction columns for every application.

Peptide Mapping
Best sensitivity with high efficiency column state-of-the-art detectors. Microbore HPLC sample-limited applications and peptide concentration.

PTH Amino Acid Analysis
Rapid resolution on MicroPak PTH-AA Col Subpicomole sensitivity with microbore HF

Oligonucleotide Purification
Rapid, high-resolution separation of deprot oligonucleotides on the MicroPak SP-oligonucleotide column.

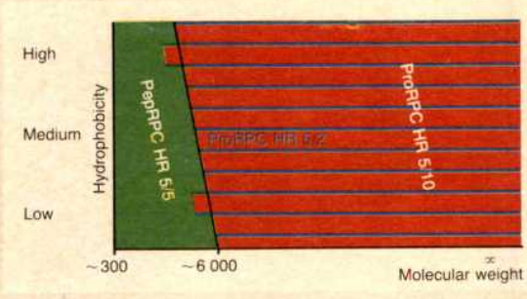
If you have to say FPLC you are half way there ...



... because PepRPC™ and ProRPC™ from Pharmacia are the state of the art in reversed phase chromatography media for separating and recovering biological molecules.

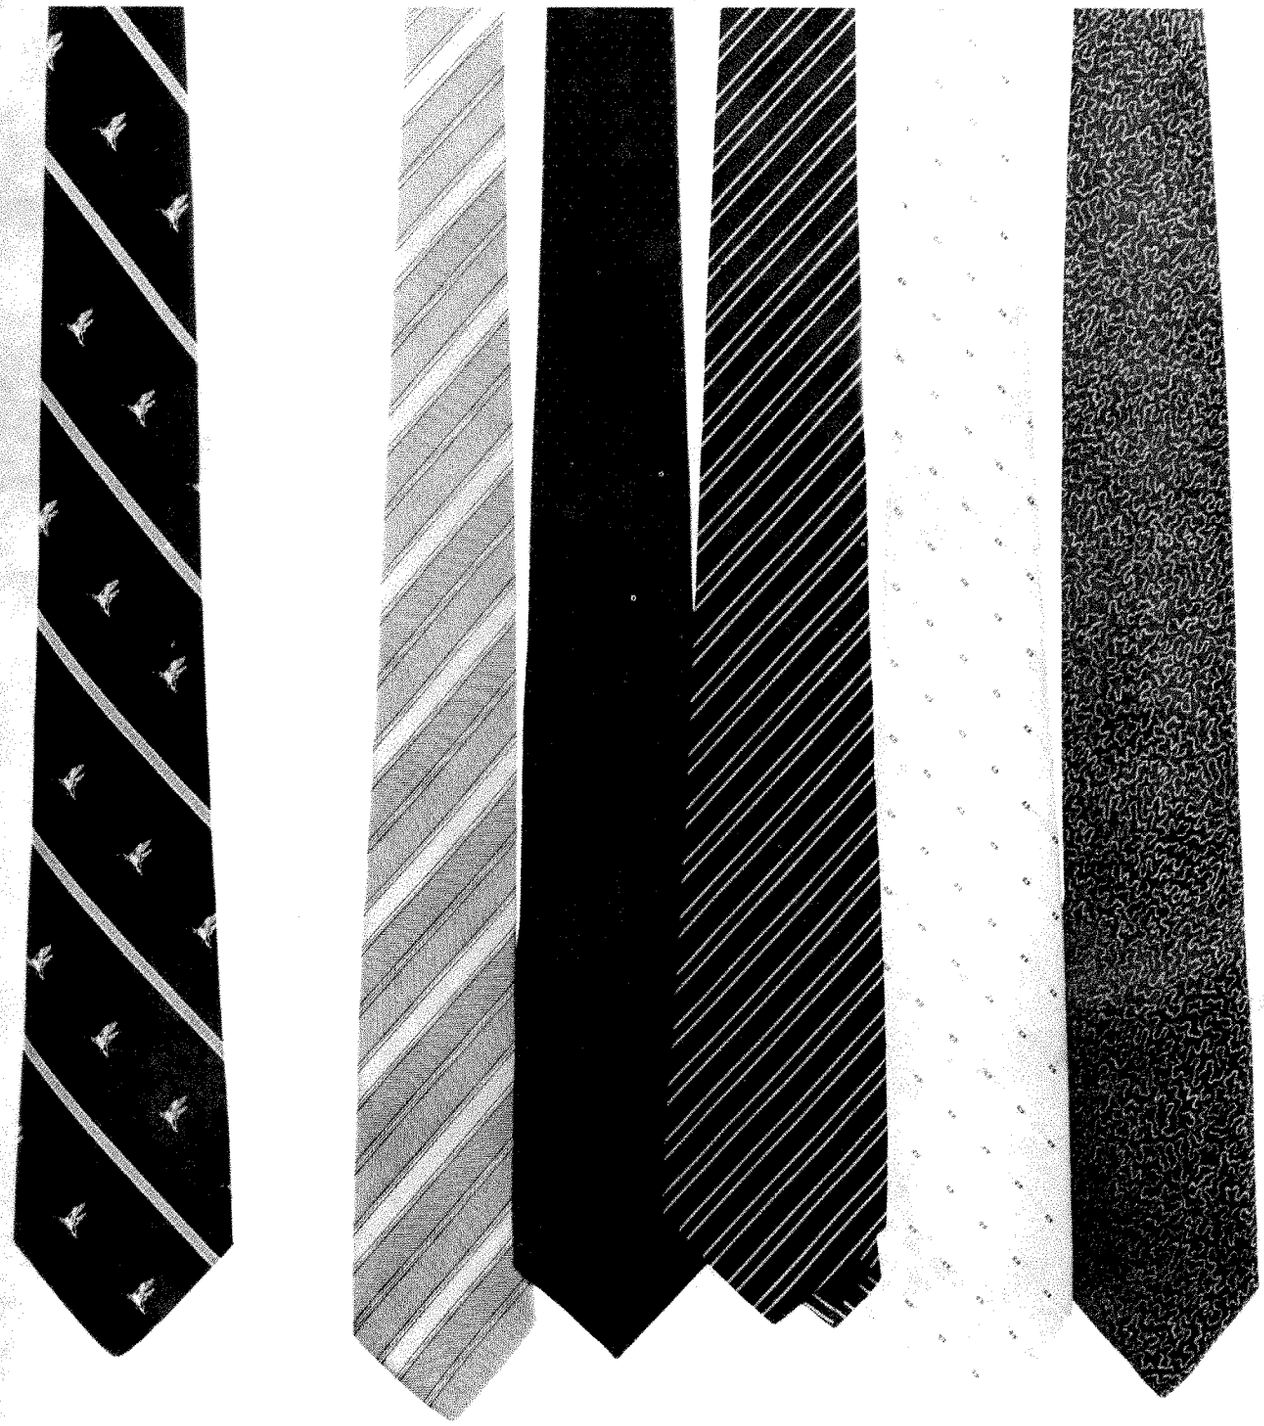
Pharmacia reversed phase chromatography columns have been specially designed for high resolution chromatography of peptides, polypeptides and proteins, forming a natural complement to ion exchange chromatography and chromatofocusing when separating biomolecules using the Pharmacia FPLC System.

Pharmacia media PepRPC and ProRPC provide you with new and unique reversed phase selectivities (C_2/C_{18} and C_1/C_8) optimised for peptides and proteins. Excellent control over the new synthesis ensures reproducibility from batch to batch.

... so go all the way.

The Pharmacia RPC media are prepacked in boro-silicate glass columns with optimised lengths to utilize a range of reversed phase separation techniques for high resolution and high recoveries of both large and small polypeptides.

- Controlled synthesis for batch to batch reproducibility
- High recoveries of peptides and polypeptides
- High resolution of hydrophobic fragments
- Optimised bonded phase composition



FPLC from Pharmacia goes beyond HPLC with biocompatibility,

The best silk will be tied up in Switzerland, but just for the day.

A business trip to Switzerland needn't involve you in an overnight hotel room, extra meals and a lot of to-ing and fro-ing in taxis which cost you time and money.

With Swissair a day-trip to Zurich or Geneva is an easy option.

Out on our first flight in the morning. Back in the evening. Whether you fly from London to Zurich, Basel or Geneva, or Manchester to Zurich, there's plenty of time for a business meeting.

You can choose between the renowned luxury of Swissair First Class, Swissair Business Class with its comfortable seating or Swissair Economy Class, if you want to fly inexpensively but still enjoy true Swiss hospitality.

A trip to Switzerland by Swissair need only tie you up for one day.

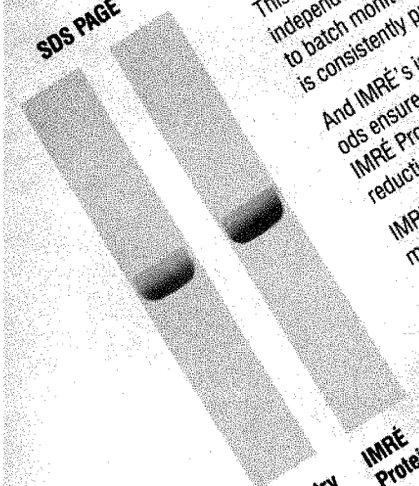
Protein A from IMRÉ: Pure Economy

Protein A from IMRÉ Corporation meets the rigorous standards of Prof. John Sjöquist, discoverer of Protein A and IMRÉ's Director of Scientific Affairs. Yet IMRÉ Protein A is available at a remarkably low cost.

IMRÉ Protein A is at least 95% pure when assayed by SDS PAGE. Thus it meets or exceeds the industry standard.



This level of purity is ensured by strict independent testing and rigorous batch to batch monitoring. So IMRÉ Protein A is consistently pure.

And IMRÉ's innovative production methods ensure consistently low prices. So IMRÉ Protein A could provide a substantial reduction in your research costs.

IMRÉ Protein A: pure economy for the most demanding research programs.

IMRÉ Protein A is supplied as an essentially salt free lyophilized fine chemical.

Please write or call for detailed specifications and a price list.

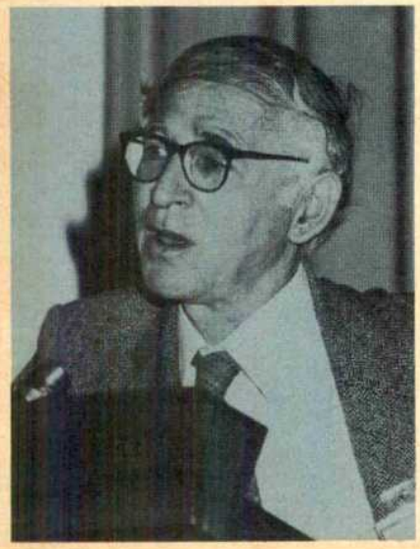
Protein A

NEW TECHNOLOGY in BIOTECHNOLOGY

In the past five years, even the enthusiasts of the new biotechnology industry have often been surprised at the speed with which new opportunities have emerged. The initial focus was on the use of *Escherichia coli* for manufacturing polypeptides and proteins.



NOW...

- other bacteria as well as yeasts are also being used and attention is turning to mammalian and plant cell systems.
- improvements to the polypeptides and proteins produced are being achieved by deliberate mutagenesis of the genes introduced into the cells.
- new strains of plants and animals are being established from engineered embryonic cells.
- the manipulation and production of monoclonal antibodies and enzymes are becoming ever more refined and the goal of representing a large protein by a much simpler peptide is within reach.
- progress is being made in coupling biotechnology to electronics, so producing sophisticated measuring devices.

As in the past, these developments spring from basic research at academic and, increasingly, at industrial laboratories.

JOIN US

at Nature's fourth international conference, to be held at the Novotel London, June 25th-27th, 1985

THE OBJECTIVE of this *Nature* conference (the second to be held in Britain) is to provide a survey of the recent research that will influence the evolution of biotechnology in the next few years.

THE SPEAKERS have been chosen for the originality of their own contributions to these topics, but they will also provide a survey of recent work related to their own immediate interests.

THE FORMAT of the conference will provide ample opportunity for discussion – each formal presentation will be followed by a question period, and there will also be appropriate round-table discussions.

PARTICIPANTS in the conference will be provided in advance with a selection of reading matter intended to provide background to particular talks.

DON'T MISS THIS OPPORTUNITY

to catch up with New Technology in Biotechnology

CONFERENCE PROGRAMME

Day 1 Tuesday, June 25th

MORNING

Enzymes, immunogens
Dr. D. Thomas, Université de Technologie de Compiègne.
Dr. G. Winter, MRC Laboratory of Molecular Biology, Cambridge.
Dr. A. Klug, MRC Laboratory of Molecular Biology, Cambridge.

AFTERNOON

Antibodies
Dr. J. Birch, Celltech Ltd., Slough.
Dr. M. Neuberger, MRC Laboratory of Molecular Biology, Cambridge.
ROUND TABLE DISCUSSION

Day 2 Wednesday, June 26th

Biosensors
Dr. M. Flanagan, University College, London
Professor I.J. Higgins/Dr. A. Turner, Cranfield/Leicester.

Micro-organisms
Dr. S. Emtage, Celltech Ltd., Slough.

Micro-organisms continued
Professor D. Hopwood, John Innes Institute, Norwich.
Dr. B. Carter, Searle R&D, High Wycombe.
ROUND TABLE DISCUSSION

Day 3 Thursday, June 27th

Mammalian systems
Professor P. Tiollais, Institut Pasteur, Paris.
Dr. A. Levinson, Genentech, San Francisco.
Dr. R. L. Brinster, University of Pennsylvania

Plants
Professor M. Fowler, Wolfson Institute, Sheffield.
Professor J. Schell, Max Planck Institut, Köln.
ROUND TABLE DISCUSSION or FINAL TALK

POSTER SESSIONS will be held each day. Those wishing to present a brief account of their own work should contact Dr. Peter Newmark, Deputy Editor, Nature, 4 Little Essex Street, London WC2R 3LF, U.K.

SPACE IS LIMITED REGISTER NOW!

TO REGISTER, return the form below with your cheque or authorised purchase order from your organisation TODAY! Applications are accepted only on completion of a booking form We ask you to complete *one form per person* We cannot guarantee to accept applications received after June 3rd, 1985

THE FEE is just £170 plus VAT for the duration of the conference or £74 plus VAT per day This includes entrance to all sessions, mid-morning coffee, afternoon tea and advance reading material Applications without payment will be acknowledged but will not be *confirmed* until payment is received In cases where a participant is being sponsored by an organisation, the organisation will be invoiced and once payment has reached us the participant will be sent confirmation of his or her place.

THE SETTING is London's NOVOTEL, situated conveniently within easy reach of the City's most famous sights and also the West End which boasts some of the world's best shopping and entertainment It is also close to the main road into London from Heathrow Airport

ACCOMMODATION has been reserved in the NOVOTEL and elsewhere for conference participants A booking form will be sent to you as soon as we receive your registration

THE CONFERENCE DINNER will be held on Wednesday, June 26th This is always a popular event and SPACE IS LIMITED so make your reservation on the form below today The cost will be £15 65 plus VAT

AN INTERNATIONAL EXHIBITION will be held in conjunction with the conference

NOTE: Cancellations received before May 27th, 1985 will be refunded less a processing charge No refunds can be made after this date

TO REGISTER FOR THE CONFERENCE, please return this form with your payment to: DEBORAH JONES, Conference Administrator, Macmillan Conferences & Exhibitions, 4 Little Essex Street, London WC2R 3LF, U.K.

NATURE VOL 315 9 MAY 1985

Too much fall-out from summit

Last week's summit meeting in Bonn was no more of a failure than its predecessors. These meetings do not settle issues, but have the virtue of putting them on the international agenda.

TAKE seven heads of government, each preoccupied with urgent domestic business, and throw them together for a couple of days with instructions to consider the world's urgent problems from the other fellow's point of view. It is a daunting assignment. Usually, after the event, the public relations people are hard pressed to conceal the disturbing truth that even world statesmen, as they are called, do not rise to the grand occasions. Their simplest trick is to make public the quarrels there will certainly have been on relatively minor issues, but at the same time to suggest that none of this can presage permanent disunity (which is usually correct). So what can the statesmen claim they have accomplished when they return to face their own electors? Prudently, they arrange that each among them has some cheerful souvenir to take home. On this occasion, there was lukewarm support for President François Mitterrand's plan that high technology should be used to help Africa feed itself, general approval almost indistinguishable from indifference for the British government's economic policies and muted acquiescence in US plans for star wars research. But the statesmen at Bonn failed to agree on the US demand that there should be a further round of talks next year on the liberalization of international trade and on the French demand that international monetary reform should be a precondition of such talks.

The temptation to blame the French for the failure at Bonn should be suppressed, if only because the French, and especially President Mitterrand, have consistently done their best to tackle other than immediate problems. Four years ago, at Fontainebleau, the cry was that technology should be made the instrument of renewed economic growth. This year, at Bonn, the plan was to rid Africa of famine by an engineered green revolution coupled, wherever appropriate, with the use of Earth resources satellites and the like. President Mitterrand is entirely right to believe that technology can work wonders, and would now be within his rights to be irritated that his fellow-statesmen do not share his vision. Where he goes wrong is to suggest that technology, admittedly a necessary part of the solution of these problems, is for that reason also sufficient. That is the illusion. While the climate and the soil of much of developing Africa are inimical to agriculture, the reasons why food production is inadequate have more to do with the willingness of African governments to sacrifice the prosperity of their peasant and farming populations to the interests of their urban voters than with the physical conditions under which crops must be grown. A summit of the seven will not put that to rights.

The French demand for monetary reform is similarly stronger on good intentions than on realism. Rapid currency fluctuations are unsettling, and bad for world trade (which may be true), so let us legislate against them. That seems to be the argument. It is a classic case of therapy by the removal of symptoms. But President Mitterrand is well placed to know that before fixed currency rates were finally abandoned in 1972, international financial crises happened just as often, but took a different form. The immediate cause of the troubles of the past few months is the large budget deficit of the federal government of the United States, and the way in which this is being financed (by borrowing from abroad rather than by printing domestically inflationary dollar bills). Since there is no way in which sovereign governments can be prevented by their trading partners from running budget deficits or even, if they choose, from letting domestic inflation run riot, the only present basis for monetary reform is an agreement between the summit states to limit the effects of bad budgeting on the international money markets. If Mr. Mitterrand had been pressing for true reform along such lines, rather than for a return of the bad old days, the United States would probably still have disagreed with him, but then he would have had reason on his side.

The US demand for a further round of talks on international trade beneath the umbrella of the General Agreement on Tariffs and Trade (GATT) is a more complicated issue. That GATT should exist is a sign of grace. That the United States should have taken the initiative in pressing for an extension of the free-trade regime is decidedly another. Politically, it might have been easier for the US administration to give in to the recent demands in Congress for a greater measure of protection from imports from overseas. But the United States was asking last weekend for an extension of the rules governing international trade that would strike at the roots of many shaky institutions elsewhere. The proposal that the rules on free trade should be extended to agricultural produce might yet make a market for Texas beef in Japan, but would certainly spell trouble for the practice of the European Community of subsidizing farmers by means of artificially high prices for food in domestic markets, while retaining the right to dump the surplus on the international markets. (One of last weekend's little ironies is that, while Chancellor Helmut Kohl was seeking emollient ways of making the Bonn communique seem good, his agriculture minister had dug in his heels, on behalf of West German farmers, against a proposal that the price of European cereals should be reduced.) The truth is that, on free trade, the United States has reason on its side and should be helped to have its way.

Star wars, the other agenda item, is more of an embarrassment for all. Two years ago, when the Strategic Defense Initiative, as it was later called, took much of the US administration by surprise, most other governments were either sceptical (as in Western Europe) or hostile (the Soviet Union). With the passage of time, the administration seems to have calculated that doubters might be turned into supporters if they were offered participation, but the terms on which this will be possible are not clear. But most of the summit governments, and certainly their electors, would be happier if the whole scheme had never been thought of. Some of them will talk about participation in the hope that helping will give them influence, but are alarmed that star wars may jeopardize the missile talks under way at Geneva.

Agreement on that issue, like most of the others raised in Bonn, lies in the future. To next year's summit, perhaps? Many of the issues raised in Bonn cannot wait that long. The US deficit will either have been made to go away, or there will be a different set of economic problems with which to grapple. But President Mitterrand may find, by next year, that he has been luckier than he now thinks likely on monetary reform, given the way in which bankers have taken fright over recent developments. If star wars have confounded the Geneva negotiations, or if these have broken down for other reasons, there will be more urgent things to talk about, which only goes to show that these summits, whatever they fail to accomplish, have become a valuable agenda of our anxieties. □

Running telescopes

Managing British astronomy is up for talks. Here is a recipe for the committee responsible.

THE first tangible product of the review of the pattern of British academically related research to which the Science and Engineering Research Council committed itself six months ago is hardly the revolution some had feared (or, sometimes, hoped for), but is none the less interesting on that account. The nub of the decision about research in astronomy announced last week is for the time being unremarkable, even hackneyed: there is to be another committee, the composition of which will be decided only next week. But in the course of inviting comments, the council says its objective is to decide what arrangements there should be for managing the two modern observatories in which the British have a majority share, at La Palma and in Hawaii. (The Netherlands, Spain, Denmark and Sweden are differently involved in one or other or even both of the projects.) By putting the question in those terms, the council has side-stepped what in the past has seemed the central question in British astronomy, that of whether the two observatories (at Herstmonceux and Edinburgh) should be merged and, if so, on which site. To ask instead the question how the new observatories should ideally be managed should provide a more constructive agenda for discussion than the many earlier enquiries on related subjects.

As things are, the Royal Greenwich Observatory (at Herstmonceux) is responsible for the La Palma observatory, to which it has donated its largest telescope, the 92-inch Isaac Newton reflector. Edinburgh, on the other hand, has had operational responsibility for the Anglo-Australian telescope, roughly 18,000 kilometres distant. (Nothing is said in last week's announcement of the importance of that instrument in the future scheme of things, confirming earlier guesses that the research council plans to trade its share of the capital equipment for a measure of observing time.) But yet another laboratory, the Rutherford Appleton Laboratory in the middle of southern England, has an important place in the management of British astronomy, both in the operations of the computer network by which data are exchanged between university laboratories and in supervision of the millimetre-wave telescope being built on Mauna Kea. On the face of things, British astronomers are overwell catered for in these respects. What the new committee should be asking is whether they should now be given a chance to look after themselves.

There is now plenty of recent experience to suggest how this should be arranged. Like other kinds of laboratories, observatories need directors, preferably persons of distinction in the field concerned, astronomy in this case. Even when the chief users are from universities, observatories also need to have a resident scientific and technical staff. Given the geography of the new British ventures, these will presumably be chosen to be as small as possible. For the rest, there need to be oversight committees, essentially trustees, and committees for the allocation of observing time, which again need not always meet in the shadow of the instruments they service. To give this pattern of management conviction with the users, some way should be found of incorporating users or their representatives in these managerial functions. These are the essential ingredients of the management structure, which happen not to involve the existing observatories at Herstmonceux and Edinburgh.

But this, of course, is not the whole of the fabric of support for a lively astronomy enterprise. The development of instruments has been shown in recent years to have been crucial to the improvement of techniques, at both telescopes, while the management and storage of data is likely to become just as important in the years ahead. But the people best placed to know what instruments will yield worthwhile results are potential users and their frequent attendants, the people with a zeal (and flair) for making things a little more sensitive or accurate, from which it follows that the research council should make grants to university astronomers for the development of instruments (which already happens), keeping up its sleeve some means for building what the enthusiasts design (best done, alongside the development of instruments for satellites, at the Rutherford Appleton Laboratory). Data management needs to be done by astronomers, not toilers in some huge laboratory, which argues for transferring this responsibility to one of the two observatories in the United Kingdom. With its recent success in designing data handling techniques, Edinburgh seems a better bet than Herstmonceux.

This is the kind of pattern to which logic leads — a single smaller observatory based in Britain, more responsibility (as for instrument design) given to the university users of the new equipment and central support in engineering from a large laboratory. So why bother with a committee? Because committees are about politics as well as reason. The choice of which observatory to close is bound to be invidious, and so is most easily made by people with an appearance of detachment. That is how the argument goes. So the research council ultimately in charge should simplify the committee's work by making clear in advance how it would deal with the people, possibly counted in hundreds, whose jobs would vanish under a brisk plan for reorganization. And the council should do its level best to practise what it has been preaching in the past few years, that astronomy is not only an end in itself but also a way of acquiring skills of general applicability, by shouldering the task of finding acceptable and useful jobs for those who may be displaced. At a time when Britain, against the recent trends, is about to be better blessed with facilities for observation in astronomy, it would be absurd that the dole queues should be lengthened by an influx of professionals in the field.

Beware junk bonds

Business in the United States, always inventive, seems bent on turning fiction into truth.

THE board-game "Monopoly" was designed in Atlantic City to mimic the real world of property speculation. Now, the financial wizards of Wall Street and similar places seem bent on adapting "Monopoly" to real life. Shadowy figures with colourful names such as T. Boone Pickens have hit on a novel way of buying up desirable companies in the stock market. The stratagem is ingenious and simple. A publicly-quoted company is singled out as a target, often on the strength of its diversity and the likelihood that its business assets are undervalued. Then a second corporation is created which offers to buy a proportion of the stock in the target in return for securities of its own, usually in the form of interest-bearing certificates. To make the deal attractive to the shareholders, the rate of interest is fixed at a level great enough to promise a return greater than the dividends earned from the target company. To lend reality to the offer, the company usually has to spend cash buying a proportion of the outstanding stock in the markets. Under United States law, it will suffice for the raider's purpose to acquire just that proportion of stock to gain control of the target company.

That is phase one. The problem now is that the shell company that has won control of its target is saddled with a load of debt, which can only be discharged by selling off the assets of what was originally the target company, exchanging the cash proceeds for the outstanding debt. In principle, these schemes will work so long as the assets can be sold for more than the nominal cost of buying half the target company. In practice it is often more profitable to offer some cash with the original purchase, for then the purchase price may be much lower. One way and another, the junk bonds outstanding from the recent frenzy of takeovers in the United States continue to be serviced. So far as anybody can tell, none of the schemes financed by junk bonds has yet come unstuck. But the amounts of money involved are so large ($9,000 million for Gulf Oil) and the basis of these deals so shadowy, that some of them are bound at some stage to run into trouble, perhaps because the assets are no longer as saleable as they seemed. Then a lot of people who thought themselves rich will find themselves poor, the common experience after the Great Crash of the 1930s from which "Monopoly" sprang. □

US agricultural research

Mission-agency seeks relief from Congress

Washington

THE Agricultural Research Service (ARS), the US Department of Agriculture's sprawling intramural research agency, is emerging from three years of austerity (some self-imposed) and reorganization with a mixed success in its efforts to polish its tarnished image with the scientific community.

ARS's administrator, Dr Terry Kinney, has scored one major success by reducing administrative overheads by $12 million out of the agency's $487 million annual budget. Less successful have been Kinney's attempts to challenge Congress's insatiable appetite for building new laboratories that for the most part serve only parochial interests.

And the most long-standing criticism of ARS — that it is not keeping pace with new developments in basic research, especially molecular genetics — persists, in spite of one notable ARS initiative, the creation last year of a plant gene-expression centre in conjunction with the University of California.

That criticism was reiterated most recently by a National Academy of Sciences panel which scrutinized ARS's research programmes at the request of ARS itself. The panel's report again emphasized the need to concentrate on developing basic understanding of plant physiology and development, insect neurobiology, immune responses in animals and other fundamental molecular processes in domestic plants and animals as well as pests.

Standing in contrast to the panel's recommendations is ARS's own 1984 annual report of its research achievements, which highlights applications almost exclusively — a new rotary disk for harvesting soya beans, a pelletized guayule seed that improves germination, a pilot plant for automatic tanning of cattle hides, a new kind of spaghetti made with 10 per cent bran.

The academy panel, chaired by Ralph Hardy, recently head of life sciences at DuPont and now president of BioTechnica, also recommended some drastic steps for ARS if it is to create the proper "climate" for good research. For example, the panel said ARS needs to be a lot tougher about offering permanent positions to scientists.

At present, the panel said, virtually all ARS scientists who are reviewed at the end of a one-year probationary period are promoted to permanent staff positions; the probationary period should be extended to five years and candidates should be evaluated by an outside group of experts.

The panel also suggested a substantial increase in ARS's postdoctoral programme; instead of 25 postdocs (actually, ARS officials say, the true figure is closer to 275), there should be at least 750. And instead of devoting 90 per cent of research budgets to salaries — as at some of the ARS's 147 laboratories and research centres — salaries should be at most 75 per cent, and in some cases as low as 60 per cent, the remainder going towards properly equipping the laboratories.

The 147 laboratories are a problem in themselves. The panel noted, as have many others before, that that is simply too many. Research groups are fragmented, preventing the formation of a "critical mass" of scientists needed to make progress.

ARS officials say that they have already dealt with many of these complaints, but that their hands are tied on the others. Federal personnel rules, for example, prohibit use of outside consultants in hiring and promotion decisions. But ARS is now negotiating with the federal Office of Personnel Management to lengthen the current one-year probationary period to three years.

Congress has been the greatest obstacle to ARS's attempts to shut down centres and laboratories that have outlived their usefulness, or which fragment the research effort. ARS did succeed in transferring the staff of the fire-ant research laboratory in Gulf Port, Mississippi, to its Gainesville, Florida, insect research centre. It hopes to consolidate several other laboratories this year.

But Congress has effectively turned down a request to rescind funds appropriated in fiscal years 1984 and 1985 for construction at eight facilities (including a Forage Seed Production and Research Center and the National Soil Tilth Center). Congress has also continued to create new facilities, such as a national centre for leptospirosis in Ames, Iowa, and a Children's Nutrition Research Center in Houston, Texas.

One way that ARS hopes to avoid being saddled with still more laboratories in the future is by writing new language into the farm bill, which is up for renewal this year. As things stand, the only way for a state to obtain federal money for a research facility is by having ARS build and operate it. The new language would open an escape valve, allowing Congress to appropriate matching funds for states to build their own facilities when they consider this necessary.

Dr Mary Carter, ARS's associate director, says that the agency has already taken steps to meet the panel's criticism of high personnel costs, and that many laboratories are already down to 65 or 70 per cent. Some laboratories where the figure is deemed too high have been ordered not to fill vacancies to correct the problem.

Carter also said that ARS is committed to expanding its programmes of postdoctoral research. Besides the 50 positions that are being created directly by the administrator's office, the research laboratories themselves hire some 250 or so postdocs.

But ARS, always under pressure from Congress — particularly Representative Jamie Whitten (Democrat, Mississippi), chairman of the Appropriations Committee — to "do something for the farmer", is drawing the line at any major tilt in favour of basic research. "We're a mission-oriented agency," Carter said, emphasizing the new ARS party line that biotechnology is merely a group of "methodologies" that can be put to use at all of its laboratories. ARS has explicitly rejected the notion of establishing biotechnology or basic research centres.

Land bows out from Polaroid

EDWIN Land, the 76-year-old founder of the Polaroid Corporation, has broken his last tie with the company. Last week, Land announced he would sell his remaining shares, which account for 8.3 per cent of Polaroid stock, and turn over a sizeable portion of the proceeds to the non-profit Rowland Institute for Science, a vaguely utopian haven for basic research that Land set up in 1981 by selling off $38 million worth of stock.

Land's remaining stock has an estimated market value of $71 million, $28 million of which is to go to the Rowland Institute.

Land resigned as chairman of Polaroid in 1982 (see *Nature* 298, 701; 1982) during a rough period for the company. The company's Polavision instant movie film, which hit the market in 1977, just as home video equipment was becoming available, proved a colossal flop, costing the company a reported $68 million. Although Polaroid's earnings began to recover from that setback in 1983, the company hit rough times again in the third quarter of last year.

The Rowland Institute, along with the Rowland Foundation that Land established in 1960 to support research and education, has increasingly been his consuming interest in recent years.

The institute, with a staff of about 80 and a new building on the Charles River in Cambridge, Massachusetts, was described by Land at the time of its founding as a place where scientists could return to "an older way of doing science", without large research teams or big machines.

Stephen Budiansky

France

New scourge for universities

IN a rather extraordinary and for the universities somewhat disturbing development in French higher education, a principal critic of the French university system has been appointed president of a new universities "evaluation committee".

The man in question, M. Laurent Schwartz, is a highly-respected mathematician at the Ecole Polytechnique, one of the "ivy-league" *grandes écoles* of France. But he is also the author of two influential diatribes attacking the French universities and prescribing certain medicines, such as a greater dose of selection and élitism, which do not appeal to the majority of university staff. These were appointed in the egalitarian boom years after the 1968 student rebellion when the universities both shifted well to the political left and quadrupled in size. To them, a Schwartzian new broom is a fearsome thing.

But how much power will M. Schwartz have? This will not be clear until his new committee, the *Comité National d'Evaluation des Universités* (CNEU), has been in place for a year and delivered its first report. But that this may come around the time of next year's general elections in France, when, according to present opinion polls, the right will return to government, will cause further alarm.

In principle CNEU is being presented as equivalent to Britain's University Grants Committee (UGC), which distributes British universities' annual "recurrent grant" from the Department of Education and Science to cover salaries and basic university expenditure such as heating and building costs. But there are important differences. On the whole, UGC is composed of university heads of department representing a cross-section of academic disciplines. In the face of university cuts, therefore, it has tended to act as a defensive body, the only notable exception being when UGC cut grants to certain smaller, mostly technological universities on the debatable basis that these universities attracted students with poorer A-level grades than others such as Oxford and Cambridge. This, in a sense, was passing the buck.

But the French CNEU promises to be different. Apart from M. Schwartz, the nine members of the "academic" side of the committee will include physicist M. Pierre Aigrain, former science minister under the previous (and conservative) French President, Giscard d'Estaing, alongside other representatives of the *grandes écoles*, and few from the university system itself. The committee is completed by five members of what might be described as an "industrial" side of the committee. Altogether, then, CNEU cannot be described as representative of the universities, as can UGC. Rather, CNEU represents a new structure on top of the universities: a new level of control.

The appointments to CNEU were announced only last week. But its terms of reference were defined in a higher education bill last year. According to these, CNEU will regularly review the work funding of the universities, considering both their research and teaching. CNEU will also measure each university against its multi-annual plan — under which a university agrees development plans with the ministry of education in exchange for a secure 3-5 year budget.

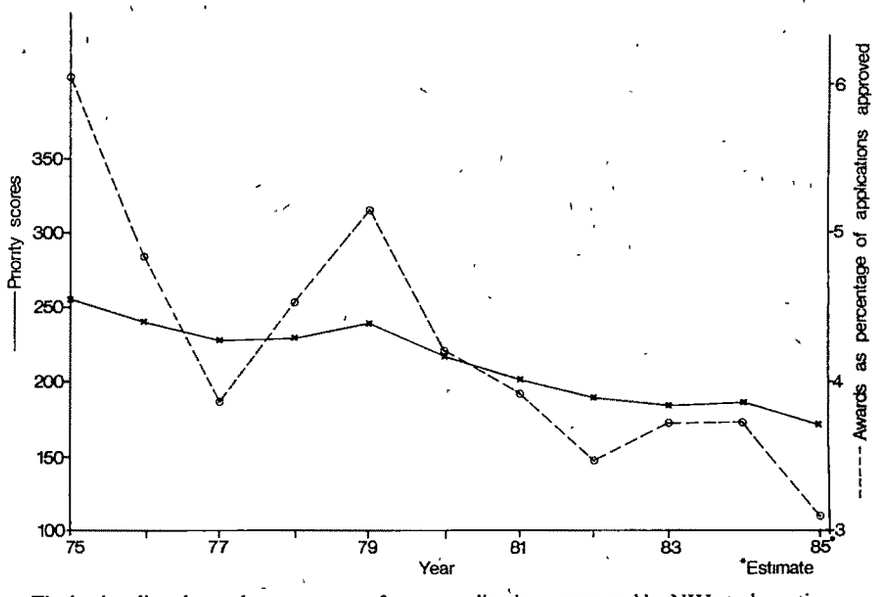
The committee will also review the new PhD system, which began only this year, and will not report to the minister of education but to the Elysée itself: to the President of the Republic, presently M. François Mitterrand.

It seems possible that M. Mitterrand, new scourge of the universities, while entering from the left, will end up by leaving from well to the right. **Robert Walgate**

NIH

More competition, more disquiet

Washington



THE Reagan administration's plan to restrict to 5,000 the number of extramural research project grants awarded by the National Institutes of Health (NIH) is having a marked effect on the priority score required of successful applicants. The estimated aggregate cut-off point for 1985 is 170, although because there have been more high-quality applications than expected, the figure may turn out to be as low as 160. The payline, as the cut-off is called, varies between institutes from less than 150 to over 200.

The Congress had requested 6,500 grants for 1985; if it prevails in the argument with the administration, the payline would be around 190. According to the latest rumours, a compromise of around 5,800 grants is likely.

Meanwhile, intramural research at NIH is also facing problems. The administration's proposed budget for NIH intramural research in 1986 is $561 million, down $16 million from 1985. NIH officials estimate that $619 million would be needed in 1986 to maintain research at its present level.

In addition, the institutes as a whole have to lose 450 man-years from their staff by 30 September, with a reduction of a further 150 man-years during the following year. The number of staff that will have to be lost by September will probably be over 600, because the instruction to reduce staff (from the Office of Management and Budget) was received only in January, one-third of the way into the fiscal year.

The problem is further exacerbated in those institutes already employing more staff than the Office of Management and Budget had assumed. Institutes in this category have initiated a "semi-freeze" policy, whereby two jobs must be lost before a single replacement can be hired. NIH officials are concerned that young untenured researchers are being frozen out and that administrative and domestic staff, who are usually tenured, will as a consequence be a growing proportion of the whole. **Tim Beardsley**

The broken line shows the percentage of grant applications approved by NIH study sections that were actually funded; the solid line shows the so-called "payline" — the priority score that 90 per cent of the funded applications had to better in order to receive funding. Priority scores range from 100 (excellent) to 500 (poor). The 1985 estimates assume 5000 grants this year; the actual number is still under negotiation.

Creation science

Rot sets in in Queensland

St Lucia, Queensland

IN Australia's sunshine state of Queensland, worried academics and teachers are preparing for a re-enactment of the "creation science" debate of the past few years in the United States. Their concern is that Queensland's Minister for Education, Mr Lin Powell, has ordered the teaching of creationism in state high schools. Whenever teachers raise the subject of evolution, they are also now obliged to present the conflicting arguments for creation and catastrophism.

Hitherto, many of Queensland's teachers have exploited a convenient loophole in Mr Powell's edict: they were not instructed how to teach creation science. But the minister now intends to close that loophole by spelling out to teachers exactly how they should present creationism in the classroom. His plans are being formulated with advice from the Creation Science Foundation (CSF), an organization that maintains a constant barrage of creationist propaganda from its headquarters in the Brisbane suburb of Sunnybank. At present, Queensland is the only Australian state where creationism is officially included in the school science curriculum, although some academics and teachers believe that it is being taught unofficially elsewhere.

CSF, which describes itself as a "faith-funded organization", publishes the glossy magazine *Ex Nihilo* at an annual cost of more than $40,000. The magazine is delivered to all state high schools in Queensland (with approval from the Minister for Education), and also finds its way into school libraries in other states.

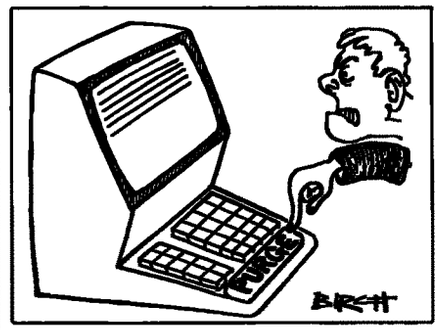
Late last year, the librarian at a high school in the Northern Territory judged *Ex Nihilo* to be unsuitable for children and requested CSF to send no further issues. CSF gave a prompt response in its newspaper *Prayer News* — it published the name and address of the offending school and urged its readers to write expressing disapproval. The editor of *Prayer News* commented that it was a "dangerous situation" when a library refused to accept a gift of *Ex Nihilo*. Eventually, the hapless school librarian capitulated under mounting pressure from CSF and its supporters.

While *Ex Nihilo* brings creationism to a general audience (including children), CSF has also launched a second periodical destined for only the most erudite creationists. The *Ex Nihilo Technical Journal* is laid out in the format of many reputable scientific journals and purports to give an in-depth treatment of the latest development in creation research.

CSF, not content merely to make inroads into the educational system, now also offers its own correspondence courses in creation science, which may be attractive to teachers seeking additional "qualifications". The gratifyingly large number of enrolments (more than 90) has prompted CSF to start selling its courses in the United States, where it already has representatives to promote sales of its literature. Most recently, CSF has revealed plans for a "world class museum as a teaching centre on creation".

So far, the creationist campaign has met no organized opposition from the scientific community. Not a single scientific society has spoken out against the bogus science of creationism. The Australian and New Zealand Association for the Advancement of Science has remained silent, as has the Australian Academy of Sciences. Representatives from all major scientific organizations, gathered in Canberra on 16 April for the inaugural meeting of the National Committee for the Promotion of Science and Technology, might well have been expected to voice some opinion on the issue, but did not.

Nevertheless, many individuals — scientists and teachers, students and parents — are beginning to express concern about the unchecked growth of creationism. On 22 March, an audience of nearly 400 gathered at the University of Queensland to hear a series of lectures exposing the fraudulent basis of creation science, as a result of which an action group has been formed in resistance to the creationist campaign.



The action group has adopted the name Australian APE (Australian Association for the Protection of Evolution), and aims publicly to refute the claims made by creationists and to press for the removal of creationism from the school science syllabus. It is assembling "survival kits" for schoolteachers who find themselves unwillingly obliged to teach creationism.

Tony Thulborn

Soviet computers

Keeping up with the students

THE Soviet Union has launched a major programme for computer literacy in schools, apparently in response to complaints by Dr Vyacheslav Elyutin, Minister of Higher and Specialized Secondary Education, that the poor performance of certain sectors of the Soviet economy is attributable to the lack of computer-mindedness among middle managers. During the coming academic year, a course in "Fundamentals of information science and computer technology" is to be introduced in all secondary schools, initially in the ninth and tenth forms (for 15 to 16 year olds), and later for younger students. Experiments are also planned in the use of computers in teaching other school subjects, as for example in processing the data obtained in physics or chemistry lessons.

Experiments in the use of computers in schools seem to have been going on for some time. According to Professor Vadim Monakhov, director of the Institute of Teaching Content and Methods of the Soviet Academy of Pedagogic Sciences, one such course was introduced in a Moscow school (specializing in mathematics) as early as 1960. Shortly before the recent Politburo decision, a Soviet television feature showed children from another Moscow secondary school using computers and visual display units under supervision and even making microcalculators and assembling printed circuit boards for local industry as part of their "work training experience".

The logistical problems of the new courses are considerable. Soviet school textbooks are usually published in editions of 4 million and software packages will have to be produced on the same scale. Dr Monakhov last month visited the United Kingdom for an international study group on the introduction of computers in schools but, on his return, told a Moscow radio reporter that although he had had considerable opportunity to get acquainted with teaching software of British companies, including Acorn and Sinclair, he found them for the most part unsuitable for Soviet use. The Soviet educationalists were therefore, he said, faced with the "tremendous" task of developing their own software.

Hardware is also liable to cause problems. It is not simply a matter of choosing the computer that is "most suitable" to the teaching profession, Monakhov explained, but also to ensure that Soviet industry is capable of producing such a computer by September. The plans for training of teachers for the new courses also seem unrealistic. Crash courses for teachers of mathematics and physics will be organized (presumably during the summer vacation). Since the Politburo decision also supposes a vast expansion of extra-curricular computer facilities for young people, organized through creativity clubs and the Pioneer youth movement, many teachers may well be faced with pupils more familiar with computers than they are themselves.

Vera Rich

Soldiers' sickness

Compensation for US veterans

Washington

ACTING under instructions from Congress, the US Veterans Administration (VA) has now spelled out its proposals for regulating compensation claims based on exposure to dioxin-contaminated herbicides and radiation from atomic tests. But VA's proposals, which were required to be based on "sound scientific and medical evidence", are unlikely to end the long-running debate over when cause and effect should be inferred in dealing with such claims.

Nineteen million gallons of dioxin-contaminated herbicides were used during the Vietnam war, but veterans have been largely unsuccessful in claiming compensation from the government for disabilities allegedly resulting from their exposure. Only 20 claims have so far been recognized.

VA's proposed regulations continue its policy of assuming some dioxin exposure for all Vietnam veterans, but are unlikely greatly to increase the number of successful claims. Chloracne is the only disease recognized by VA as likely to result from exposure to the most potent dioxin isomer, 2,3,7,8-TCDD, and then only if symptoms appear within 3 months of military service.

Generally, compensation is paid for all medical conditions which appeared during service, and for some chronic diseases appearing within a year of discharge. In borderline cases, compensation is awarded if there is reasonable doubt. Most claims fall outside these categories, however, as they are based on diseases appearing years later.

VA was requested by Congress to consider specifically how it would deal with claims linking dioxin exposure with soft tissue sarcoma and porphyria cutanea tarda, a liver disorder, but has concluded that neither disease has been convincingly shown to result from dioxin.

Most of the evidence on the human health effects of dioxin comes from studies of industrial exposure and from the Air Force's Ranch Hand study, which found some suggestive but equivocal evidence linking relatively high levels of dioxin exposure in spraying crews to increased incidence of skin cancer, birth defects and neonatal deaths.

Firmer answers should emerge from a $75 million epidemiological study by the Centers for Disease Control (CDC) of health effects of Vietnam service and dioxin exposure, recently mounted. Some 30,000 veterans will be interviewed by telephone, of whom 10,000 will be given thorough physical examinations at special clinical facilities constructed at Albuquerque, New Mexico. CDC are also carrying out a case control study of those particular cancers suspected of having being caused by dioxin. The results should be available before the end of the decade.

Veterans who participated in above-ground nuclear weapons tests in Nevada and in the Pacific have been just as unsuccessful in prosecuting compensation claims as the Vietnam veterans. Only 20 cancer cases have been recognized as due to service-related exposure to ionizing radiation. VA's proposed regulations allow possible claims based on leukaemias and bone cancer appearing more than two but less than 30 years after exposure (excluding chronic lymphatic leukaemia), and those based on thyroid, breast, lung, liver and skin cancers occurring more than 10 years after exposure. But, because many of these conditions are relatively common in the general population, few cases are likely to be recognized.

The central argument in radiation-linked claims has always been over the size of the estimated dose. Estimates based on film-badge records, for example, take no account of ingested and inhaled radioactivity, which were probably not negligible in tests where soldiers had to run towards a bomb crater throwing hand grenades. The Defense Nuclear Agency has attempted to fill the gap by making estimates of dose through these pathways, and these are used in a major study of mortality among atomic test veterans that is to be released later this month by the National Research Council's Medical Follow-up Agency. This study, directed by Seymour Jablon, traces mortality among 50,000 test veterans, roughly one-fifth of the total.

But even this will not be enough to satisfy veterans' organizations and the Congress. Acting again under instructions from Capitol Hill, VA is considering the feasibility of an epidemiological survey of test veterans to determine the incidence of morbidity. VA's deliberations are being overseen by Congress's Office of Technology Assessment (OTA), which will shortly publish a feasibility study on the survey. According to Michael Gough of OTA, the Defense Nuclear Agency's dose estimates are likely to be challenged by veterans' representatives, so the question boils down to by how much the dose estimates must be wrong for detectable excess cancers to occur. Whatever OTA recommends, however, the final decision on the epidemiological survey will rest with VA, which may well decide to proceed with the study in order to silence criticism.

Tim Beardsley

Environment

Japanese move to save forests

Tokyo

A GROUP consisting largely of academics has formed in Japan, the world's first society for the promotion of "Green Civilization", which it is hoped will grow into an international organization. Founder members include Kenichi Fukui, Nobel prize-winner in chemistry, and Mostafa Tolba, secretary-general of the United Nations Environment Program.

The organization has been set up largely because of concern over increasing deforestation and desertification of the Earth through poor agricultural practices and industrial pollution. The move is significant in that Japanese companies have been heavily involved in the destruction of tropical rain forest in South-East Asia. Indeed, the nation was dubbed an "ecological menace" in a report adopted last month by the environment commission of the European Communities for "pillaging natural resources in the most irresponsible way possible, and ravaging tropical rain forests for hard woods".

During Japan's "high-growth" phase, huge tracts of land were stripped of all vegetation in many parts of South-East Asia to provide building materials and pulp for Japan; although direct involvement by Japanese companies in the worst of these practices has now lessened, the amount of tropical forest lost each year has increased and Japan remains the major Asian market. The Green Civilization Society says it intends to try to put the ecological point of view over to industrial companies involved in logging but it is clearly not about to become a grass roots political pressure group.

Unlike Friends of the Earth, much of whose ideology it appears to share, the Green Civilization Society is to be a more academic body. It is believed that by building an interdisciplinary academic movement — for example of ecologists, biotechnologists and forestry researchers — more rational and less destructive means of forest management could be found that could be incorporated into recommendations to the government. Within Japan itself, forestry is regulated by laws devised in the nineteenth century which were meant to provide a balance between exploitation and regeneration of the forest. These laws are no longer effective but will only be changed, Green Civilization members say, by a joint effort between ecologists, forestry researchers and lawyers.

The society has now around a hundred members, most of them drawn from the universities. At the inaugural meeting last week, Seiji Kaya, former president of the Tokyo University, was elected chairman and Michio Tsutsui, professor of forestry at Tokyo University, vice-chairman. So far, funds are being raised mainly from individuals, with some contributions from industry. One hope is that enough money can be raised to provide a "Green Nobel Prize". The establishment of the new group coincides with the designation of this year as International Forestation Year by the United Nations.

Alun Anderson

Japanese tokamak

Plasma now in production

Tokyo

PLASMA was successfully produced in Japan's giant JT-60 tokamak fusion machine for the first time last week. Although this milestone has long since been passed by both of JT-60's competitors — the Tokamak Fusion Test Reactor (TFTR) at Princeton in the United States and the Joint European Torus (JET) at Culham in England — any of the three might be first sometime around 1987 to reach the immediate goal of break-even.

JT-60 scientists were clearly very pleased at how smoothly the tokamak had run. Operation began in April and produced plasma exactly as expected almost immediately. The machine was then run in a discharge cleaning mode to remove impurities from the inner sides of the vacuum chamber and shut down for the installation of diagnostic apparatus which will be used to monitor plasma parameters in the next phase of development.

In the first test run, ohmic heating alone was used and temperatures in the 100-200,000°C range achieved for around 80 milliseconds — a long way from the 100 million degrees and 1-second confinement needed to achieve the break-even condition when the reactor produces as much energy as it consumes. But to achieve that goal, JT-60 will not be following quite the same route as either TFTR or JET.

Unlike either of its competitors, JT-60 will use radio-frequency waves to drive current in the plasma. In the other designs, currents are induced to flow in the plasma by a set of coils around the tokamak that act as the primary winding of a d.c. transformer — the plasma itself acts as the secondary winding. But such a system allows only pulses of current to be produced, for in a d.c. transformer the current in the primary would have to increase indefinitely to continue to drive current in the secondary, a clearly impossible condition. Driving the current by radio-frequency waves, however, allows operation to continue as long as needed as electrons are pushed along the magnetic field by transfer of the waves' momentum.

The JT-60 team is also proud of the neutral beam injector equipment that will be used to heat the plasma in the future. All three tokamaks are using neutral beams but, according to Masaji Yoshikawa, director of Large Tokamak Research at JT-60, the Japanese designs are at least a year ahead of the others in their technical development.

JT-60 also incorporates a unique method of dealing with impurities — metal atoms or gas molecules that may be knocked out of the tokamak inner wall by the plasma — in its magnetic limiter or divertor, and if it works as predicted, will provide a crucial advance towards practical fusion. The idea is to give the plasma in the tokamak a figure of eight, rather than circular, cross-section, and to keep impurities away from the main body of the plasma in the upper "circle" of the figure of eight.

JT-60 is now expected to be run until the end of June with ohmic heating and then shut down for six months while both neutral beam and radio-frequency heating systems are installed. Next year, power will be put into the plasma from all the systems and, if all goes well, break-even will be reached in the winter of 1987.

All these experiments are to be run with a hydrogen-deuterium plasma; there is no intention to switch to the deuterium-tritium plasma that would be used in a commercial reactor and will be the subject of second-stage experiments for both TFTR and JET. Neutrons produced in the latter reaction are very energetic and make the whole tokamak radioactive; expensive and difficult remote handling techniques thus become essential.

The Japanese are leaving this stage to their next reactor, the fusion experimental reactor, which will follow JT-60. That is, rather, if some form of massive international effort does not follow on from the three projects now running. Increased costs are making the advantages of international cooperation more and more obvious and recent talks have produced hopes that it might eventually take place.

Hungarian education

New law spawns discontent

HUNGARY's new education law, passed last month, lays special stress on the unity of education and research, and the need to provide more flexible forms of post-university training, according to the Minister of Education and Culture, Mr Bela Koepeczi. Presenting the bill to the National Assembly (Parliament), Koepeczi said that although it is not the task of the law to lay down specific conditions for higher and postgraduate education, the new law makes it clear that the provision of proper material conditions in the education sector is the duty of the government. And the government, he assured the assembly, has undertaken to continue its investment in the reconstruction of the universities and to improve the supply of equipment and other necessities for university-based research.

The new law, which replaces the existing legislation of 1961, covers the whole educational process from kindergarten to postgraduate and is intended not as a radical reform but as a gradual process of development, Koepeczi explained. The prospect of new legislation, however, triggered a debate in the universities on academic autonomy, and, in particular, the allocation of senior appointments. A number of academics, Koepeczi said, have gone so far as to press for "decentralization". This term is at present used in Hungarian political circles to mean the reform of 1982, by which industrial enterprises elect their own managers (choosing from at least two candidates). In other words, these scholars advocate that the universities should be allowed to elect their own rectors and senior administrators.

This, Koepeczi says, is not a true "materialization of democracy" since the appointments in question are the concern not only of the institutions individually, but also of the wider scientific and professional community. Although, therefore, the new law gives the universities considerably more control over syllabuses, teaching methods and day-to-day administration, senior appointments will still be the concern of the government or of the relevant minister. "Democratization" will continue to be ensured by the government or minister consulting with the relevant committees of the Hungarian Academy of Sciences, which thus serve as a kind of watch-dog for scientific public opinion.

Since, in Hungary, members and researchers from the Academy of Sciences frequently simultaneously hold university posts, the system has so far worked reasonably well. The "decentralization" lobby, therefore, seems to have based its stand rather on a matter of principle than on the need to reform any current shortcomings.

This inevitably evokes the question whether the "decentralizers" have not, to some extent, been influenced by the present endeavours of the Polish universities to retain the autonomy won in 1980-1981, in which the right of the universities to elect their own rectors and deans is one of the most burning issues.

Naturally, Mr Koepeczi made no reference to the Polish situation in his address to the National Assembly. The new law was presented as a purely Hungarian concern. Nevertheless, on one point at least, those responsible for drafting the law seem to have had an eye on developments in Poland. In drawing up the bill, the government, Koepeczi said, considered it extremely important to provide a legal background to the operation of student "self-government bodies"; an issue that has so far aroused no great controversy in Hungary, but which in Poland is at present a major point of confrontation between the vast majority of the student body (over 90 per cent in some universities) and the governmental Committee for Social and Political Questions which seeks to reduce the self-government committees to a mere adjunct of the Party youth movement.

Vera Rich

The embryo's right to protection

SIR — The opponents of all human embryo research seem to have shifted ground, from the meaningless proposition "life begins at fertilization" to the argument that a human embryo is inherently entitled to full human rights by dint of genetic uniqueness and potential. R. Watson (*Nature* 7 March, p. 10) goes so far as to assert that there can be "no objections" to the idea that a unique potential individual is created "at fertilization".

Leaving aside the difficult questions of when fertilization can be said to have occurred (at sperm penetration, at pronuclear formation, or at activation of the paternal genome some hours or days later?), and of clear differences in potential between embryos, the assertion does not bear close scrutiny. If anything, the beginnings of genetic uniqueness occur in the forming gametes, during the second meiotic division. Here genetic information is exchanged between pairs of homologous chromosomes (the chromosomes of the embryo's *grandparents*, in fact): in the egg this will have occurred several hours, and in the spermatozoon, several weeks before fertilization. If the embryo is to be granted "rights" on the grounds of genetic uniqueness and potential, how can we logically withhold similar "rights" from the gametes? What of the "rights" of the polar bodies, so wantonly cast aside during oogenesis, and yet clearly of human origin and containing genetic information capable, if suitably nurtured and combined, of potential humanity? One could push the argument for "rights" back still further, to parental embryos, when the germ cell lineage separates from that of the somatic tissues: who can deny that to destroy a primordial germ cell prevents it from fulfilling its life-transmitting potential?

My purpose is not to argue that embryo research should not be constrained, nor that the embryo is worthless. Rather, it is to point out, yet again, that the transmission of life and of human identity forms a continuum, and that there is no point at which human potential suddenly jumps into existence. Setting such arbitrary points may give us the warm glow of moral certainty, but the exercise is not supported by the real complexity of biological systems.

University of Queensland,
St Lucia, Queensland,
Australia 4067

SIR — The legal and moral status of embryos and the way in which they are handled are the subjects of a complicated debate. R. Watson (*Nature* 7 March, p. 10) seeks to simplify the topic by referring to a clear topological event, fertilization, "at which a unique member of our species is created". One problem with such an oversimplification is that it may be applied to give silly conclusions.

I contend that each member of a pair of identical twins is a unique member of our species, even though both result from one fertilization. I believe that it is (and should be) illegal to murder one, or to use him or her destructively in medical research. I reach the decision that it is morally wrong to kill a member of a pair of identical twins by deciding that each is a separate, thinking, feeling person, and not by some simple topological argument about the moment when a genome is created.

Of course one might argue that any mitosis (like that which produces identical twins) is an event "at which a unique potential member of our species is created", since it is probably possible to freeze any human diploid cell, await the development of practical human cloning by nucleus transfer, and make an individual of that cell. The killing of single human cells is neither legally nor normally the equivalent of homicide nor, I contend, should it be. This line of argument, too, is an oversimplification.

Whether the benefits of research on embryos (or of abortions) outweigh the disadvantages of destroying embryos is a complex and difficult question. We should address that complex question without looking for quick and easy definitions of what is a person.

Genes and intelligence

SIR — Summarized briefly, John Hartung's hypothesis (*Nature* **311**, 515; 1984) is that ill health caused by genetic factors may indirectly affect the intelligence. The principle point of my letter (*Nature* **313**, 425; 1985) was to question that *a priori* assumptions that intelligence and school attendance are linked and that hay fever impairs intellectual performance. Both these assumptions may be true, but they are unproven. Since Dr Hartung's hypothesis depends directly on the validity of these assumptions and since they may be tested empirically, it is essential to his argument that they should be examined experimentally.

His reply (*Nature* **314**, 398; 1985) deals largely with the viscosity of gases. Of course he is right that the viscosity of gases increases with temperature; he was wrong in his original letter to suggest that humidity also increases viscosity. The problem is, however, far more complex. For instance, the air flow in the nose is turbulent and resistance will therefore depend on gas density, being in general terms less in humid air than in dry air. The shape of the nose is obviously not wholly dependent on climate. This is illustrated by the observation that the inhabitants of the dry desert regions of North Africa and the Middle East, where natural conditions provide the most viscous air to be found on Earth, are not noted for short noses with wide nostrils.

I agree with Dr Hartung that the search for genetic differences that may also affect intelligence is a proper subject for scientific enquiry. My familial credentials are even more extensive than his, since I can claim to be the son and nephew of both men and women who served in the fight against Hitler's Germany. I think, though, that Dr Hartung would agree with me that neither moral nor political rectitude are genetically determined characteristics. The assertion of familial virtue is no guarantee of the value of his opinions or of mine.

Goldfarb's letter

SIR — In your latest article on the Goldfarb case (*Nature* 28 March, p.307), my name is mentioned as follows: "During his recent conversation with KGB officer Gusev, Dr Goldfarb was confronted with a copy of a letter he had written to Professor Elie Wollman of the Institut Pasteur in Paris, supporting the idea of the moratorium." Gusev said that the letter might constitute a case of 'anti-Soviet propaganda' and made Dr Goldfarb sign a document to that effect".

I wish to make a few points clear.

- I have known David Goldfarb for many years, because he was a pioneer in introducing bacteriophage and bacterial genetics research in the Soviet Union. I consider myself a close friend of this exceptional man, both professionally and personally.
- Our correspondence is brief, containing only personal news of the usual kind, and neither him nor I ever approached in writing any subject that could be interpreted as being controversial in the broad sense of the word.
- I have received no letter from Goldfarb for about a year and was astonished at not even getting a Christmas card, although I wrote to him at the New Year.
- I never received the letter mentioned in your article. There are therefore three possibilities:

(a) such a letter does not exist and has never existed;
(b) the letter exists and has been diverted by the Soviet secret police;
(c) a fake letter has been manufactured.

Hypothesis (b) seems to me to be excluded for the reasons given above.

Black hole at the galactic centre

The latest accurate measurements of the size of the galactic core at centimetre radio-wavelengths leave no reasonable escape from the conclusion that there is a black hole at the centre.

WE HAD best learn to live with the idea that there is a black hole at the centre of our Galaxy. That is the implication of the article by K.Y. Lo *et al.* on p.124 of this issue. Perceptive readers will think the paper, which is the culmination of eight years of observation of the galactic centre with coordinated radiotelescopes separated by great distances, is over-modest. Others may think it over-cautious. The phrase "black hole" appears only once, and then as a quotation from an article by Lynden-Bell and Rees, who first floated the idea.

The new development is essentially nothing but a more accurate measurement of the diameter of the radio source known, for the past decade and more, to be located at the galactic centre. The result is startling. At the shorter of the two radio-wavelengths (1.35 cm) at which measurements have been made, the angular diameter of the source is merely 0.002 second of arc (2.1 milli-arc seconds), which at the distance of the galactic centre corresponds to a physical diameter of about 20 astronomical units, the size of the Solar System within the orbit of Saturn. At the longer wavelength (3.6 cm), the source at the centre of the Galaxy appears to be shaped like an ellipsoid with a long axis lying only 8 degrees away from the rotational axis of the Galaxy as a whole.

The case for supposing that there is a black hole at the centre rests almost entirely on the difficulty of accounting for such a prolific source of radio emission in any other way. Lo *et al.* argue that the supposition that the galactic centre might be the site of a rapid burst of star formation, tenable when the limits on the size of the central source were more than a hundred times greater than they have now become, plainly cannot be accommodated within a region no bigger than the orbit of Saturn. A stellar system which is a powerful source of radio emission might fill the bill, but only artificially; such systems are short-lived compared with the lifetime of the Galaxy. Black holes, on the other hand, endure (unless they are very small compared with the masses of typical stars) and even grow more massive with the passage of time. By default, the presence of a black hole at the galactic centre emerges as the simplest explanation of the new observation.

But is it not disconcerting that such an important and interesting conclusion should rest on such a negative argument? That is a natural but not a particularly pointed question. Black holes as such are by their nature invisible, although that does not apply to whatever matter may be dragged by gravitation into such an entity. Captured material, whatever its chemical composition, will be unspecifically ionized and will yield synchrotron radiation if there are magnetic fields to play with. Visible radiation will however be absorbed (or converted into low-frequency radiation) by the molecular and dust clouds lying around the galactic centre. Infrared observations are also limited in this way, as well as by the mismatch between the resolution of the telescopes for the time being available and the angular diameter of the source. This is why long-baseline radio-interferometry is, for the time being, the best hope for an unambiguous description of the object at the galactic centre.

In the circumstances, the temperature of the source estimated by Lo *et al.* means very little, for the radiation distribution is clearly very different from that of a black body. But the temperature (100 million K) is an accurate measure of the intensity of the radio-emission from the central object and its surroundings. The variation of the apparent angular size of the object with the wavelength of observation is surprisingly tidy — a simple proportionality to the square of the wavelength. The interaction of radiation with electrons is implicated in some way, but just what form this takes will depend, Lo *et al.* say, on the construction of a brightness map for the source.

There is little that can at present be said about the mass of the black hole at the centre of the Galaxy, and indeed a mere measurement of the geometrical size of the region from which radiation is emitted can be neither here nor there. But measurements such as have been attempted in the past few years of the motion of objects, stars and clouds in the neighbourhood of the centre should eventually help to define the mass of the object. As things are, systematic studies of the velocity distribution of nearby objects are inconclusive and open to conflicting interpretations. But presumably it is a matter of time spent on observations before something can be said about the variation with distance of angular velocities of nearby objects about the centre of the Galaxy, from which it should be possible to infer what mass there is at the centre.

Meanwhile, studies of this kind are for some time likely to be more profitable when applied to other galaxies than this. So much should be clear from the account two weeks ago by C.M. Gaskell (*Nature* **314**, 672; 1985) of the recent demonstration by J.L. Tonry that there is a black hole at the centre of the dwarf galaxy M32, a satellite of M31 (Andromeda). The technique is to determine the non-radial velocity of central objects as a function of radial distance from the centre, which should be a measure of the mass lying within that distance. Gaskell explained some of the pitfalls in this process, and in particular the failure by these means to demonstrate the presence of a black hole in M87.

The implications of these developments for the present understanding of galactic evolution are clearly important. Any galaxy, if left alone, should eventually collapse under its own weight after several repetitions of the cycle of stellar nuclear synthesis. So there should be no surprise that the end point of galactic evolution should often be a black hole, one whose mass is not very different from that of the original galaxy. That black holes begin forming (at least in M32 and in this Galaxy) is not surprising either, but it is helpful that at least two cases of this phenomenon are now known. To generalize from two cases, one an elliptical galaxy (M32) and one a spiral (this), may seem rash, but it would be no great upset for the applecart if most galaxies turn out to have a black hole at the centre.

As is now generally understood, this seems to be the case for active galaxies, quasars spectacularly but other active galaxies such as Seyfert galaxies as well. But it remains to be told whether the difference between such a galaxy and this, where the central black hole is only a modest source of radiation, lies simply in the amount of material accessible to the central attracting source or whether there is something extra special about quasars and similar galaxies. The importance of answering that question is that it will decide whether quasars are exceptional galaxies rather than ordinary galaxies in a particular (and brief) stage in their evolution.

Meanwhile, this development has no immediate bearing on the grander cosmological question of whether there is enough hidden mass to close the Universe, or eventually bring the present expansion to a halt. The mass of the black hole in M32 is estimated at 5 million solar masses, a tiny fraction of the whole. The black hole at the centre of this Galaxy, whatever its mass, is unlikely to be much bigger. So the missing mass that matters must still be sought elsewhere.

John Maddox

Neurobiology

Why flying locusts do not crash

from Jonathan Bacon

LOCUSTS manage to remain aloft for long periods while avoiding crashing into obstacles, their companions in the swarm, or the ground. Studying how they achieve this has kept some biologists busy for almost 40 years but only comparatively recently has the technology been available to examine the neuronal interactions that control these manoeuvres. Intracellular recordings can now be obtained from restrained locusts that still produce the motor rhythm of flight. A paper on page 142 of this issue[1] describes how sensory interneurones that convey information about flight-course deviation interact with the neurones of the flight motor to mediate steering responses.

When a locust is attached to a support so that the legs do not contact the ground, it will 'fly' for as long as a windstream is blown on its head[2]. The early observations were made in the Sherringtonian climate of the time, when it was thought that sensory input was needed to stimulate each reflex burst of motor activity. In terms of the locust flight motor, this implies that each beat of the wing would produce the necessary feedback to stimulate the next wing beat. In 1961, D.M. Wilson performed one of the classical experiments that was to change this way of thinking[3]. By systematically removing the wings, the top half of the thorax, the abdomen and even the head, he showed that what remained of the nervous system (the thoracic nerve centres, or ganglia that contain the flight motor neurones) was still able to produce a burst of motor activity in response to a puff of wind or an electric shock, although no rhythmic sensory feedback remained. This demonstrated irrefutably that the animal can produce a patterned motor output in the absence of patterned sensory input and established the locust flight motor as a classical example of a central pattern generator (CPG).

Although sensory inputs are patently not required for the locust flight CPG to function in the laboratory, they are necessary in proper flight where turbulence is encountered and the ground and other obstacles are to be avoided. Two sensory cues that help the animal to fly a straight, level course are wind direction and the position of the horizon. Wind direction is monitored by banks of tiny hairs on the head, which the animal uses to determine the attitude of its flying body with respect to the air mass. By constantly making tiny adjustments to its direction of flight through changes in wing stroke, the animal strives to maintain a symmetrical air flow over its head[2,4].

Apparent changes in the slope of the horizon are detected by the large compound eyes and the ocelli, simple light-detecting organs on the head. If the horizon suddenly moves upwards in the animal's field of view, the wing beats are modified to correct the dive. Similarly, L.J. Goodman reported that when the horizon appears to slope to the right, the wing beats are adjusted until the horizon again appears horizontal[5]. The horizon stimulus is very powerful — a locust flying in a device that allows it to rotate freely about its longitudinal axis can be made to fly upside down by inverting the artificial horizon[5].

Clearly, if the neurones of the thoracic ganglia responsible for producing the correctional changes in the motor output to the wings are to react swiftly to deviations in the flight path, they must be constantly appraised of, among other things, wind direction and horizon position. Several descending sensory interneurones that run from the head ganglion to the thoracic ganglia are candidates for the fast sensory pathways[6,7]. Early attempts to investigate the cellular basis of steering behaviour sought an explanation in terms of direct connections between these descending interneurones and flight motor neurones, but the synaptic potentials recorded in the motor neurones are very small (and variable) in relation to the massive membrane potential oscillations seen in flight motor neurones in real flight[8]. Although direct synaptic connections between descending interneurones and flight motor neurones certainly exist, they are probably too puny to mediate the rapid steering responses.

Progress in analysing the steering reactions was hampered because the flight motor neurones were the only components of the neural network in the thoracic ganglia that could be identified with certainty. Because sensory neurones are easy to stimulate and muscles easy to record, most workers concentrated on the sensory influences on the flight motor rather than on the working of the motor itself. This contrasts with work on locomotor patterns in soft-bodied invertebrates, such as the leech and the mollusc, where the sensory apparatus is difficult to stimulate precisely and muscles are more difficult to record but the central neurones of the CPG are easy to see and impale.

Further progress could not be made unless the rhythmically active elements of the flight CPG, the cells that must have been active in Wilson's original deafferented preparation[3], could be monitored directly. The breakthrough came when R.M. Robertson and K.G. Pearson developed a physiological preparation in which intracellular recordings from thoracic interneurones could be obtained during a burst of activity in the flight CPG[9]. With much painstaking probing of the neuropile, they have identified sets of interneurones that show rhythmic activity at different phases of the flight cycle, of which some are premotor and some receive sensory inputs[10]. A third type belongs to the flight CPG — current injected into such a cell will reset the whole flight rhythm[10]. Though much work remains to be done, it seems that a description of the neuronal interactions producing the locust flight CPG is likely to emerge from studying the synaptic interactions between some of these thoracic interneurones[11].

Reichert *et al.* have now modified this preparation for investigating the neuronal control of flight steering[1]. They provide the locust with a combined horizon and wind stimulus that can be moved to simulate the pitches, rolls and yaws that the animal would experience in flight. The authors reliably identify three pairs of descending interneurones that convey sensory information from the head to the flight circuits of the thoracic ganglia. Each neurone responds to different combinations of wind and visual stimuli with an output that has specific directional characteristics, termed by the authors the "emergent modality" of the neurone.

Even more interesting is the interaction of the output from these deviation detector neurones with thoracic flight neurones. Essentially, Reichert and his colleagues have repeated Goodman's experiment but with intracellular monitoring of interneuronal activity. If the animal could break free of the pins holding it stable for intracellular recording, the changes in flight motor output would enable it to correct for the movement of the horizon stimulus.

The descending neurones make only direct connections with flight interneurones but these have strong inputs to a rhythmically active set of thoracic interneurones. This set also receives a large input from the flight CPG and is presynaptic to flight motorneurones. They therefore effectively act to gate the tonic output of the descending sensory interneurones, so that it is transformed into a phasic input to the flight motor.

Although this newly described mechanism is important because it ensures that the signals from the deviation detectors are delivered to the relevant motor neurones only in their active phase, it is not certain that the information conveyed by the deviation detectors is "intrinsically phase in-

dependent" in real flight. At least one pair of wind-sensitive interneurones in the locust is known to be phasically active in flight because the animal's own wing movements inevitably produce phasic wind turbulences around the head[12]. Since the three deviation detectors are also wind sensitive, they too may well be modulated at the flight frequency and so the information they carry about horizon movement would already be phasically modulated. However, this modulation would be lost in a fixed preparation.

While work on this kind of preparation is the only way to make progress in understanding flight stabilization behaviour, it does suffer the limitations inherent in immobilizing an animal to study locomotor behaviour. Inevitably, the feedback from the environment is very reduced or completely missing. Any study in neuroethology is bound to be an exercise in compromise because intracellular recordings cannot be made in freely behaving animals and intracellular prepartions cannot freely behave. Nevertheless, this work on restrained flying preparations is an important step in understanding the neural circuitry that converts sensory signals to motor output. □

Superconductors

Induction of superconductivity by applied magnetic fields

from M. Brian Maple

PHYSICISTS have been fascinated with the interplay between superconductivity and magnetism for nearly three decades, during which period many new and interesting phenomena have been reported (see ref. 1). One of the latest, reported by H.W. Meul and colleagues[2], is the induction by a high magnetic field of superconductivity in europium-containing metallic compounds of the type $Eu_xSn_{1-x}Mo_6S_8$, where x ranges from 0.7 to 0.8. This is a remarkable observation in view of the fact that applied magnetic fields generally destroy superconductivity. It is perhaps equally remarkable that the mechanism apparently inducing the superconductivity, and known as the exchange field compensation effect, was originally suggested more than twenty years ago by V. Jaccarino and M. Peter[3].

Despite previous indications of S-N-S-N (S, superconducting; N, normal) behaviour in related compounds in high magnetic fields[4,5], it has not been possible to establish the occurrence of magnetic field-induced superconductivity (MFIS) because of the rather broad transitions encountered. Meul *et al.* overcame this problem when they found that the addition of small amounts of Br or Se to the compounds sharpens the transitions. At the same time, they adjusted the superconducting transition temperature, T_c, to within the narrow range of values required to observe MFIS, which was measured in terms of the electrical resistance, R, which has a finite value in the normal state and vanishes in the superconducting state. The inset in Fig. 1 shows normalized electrical resistance (R/R_N) versus applied magnetic field (H) at several temperatures for one of these compounds — $Eu_{0.75}Sn_{0.25}Mo_6S_{7.2}Se_{0.8}$. The data at the lowest temperature (0.37 K) clearly reveal a succession of transitions with increasing magnetic field — from superconducting to normal, to superconducting again, and finally, back to normal (S-N-S-N). From a series of measurements of R/R_N versus H at various temperatures, a phase diagram in the H-T plane was constructed (Fig. 1); two separate domains of superconductivity are found, one at low fields and another at high fields, whereas in a conventional superconductor only one domain of superconductivity at low fields is present.

In order to understand the sequence of superconducting to normal transitions observed, the nature of the superconducting material must be considered. The $Eu_xSn_{1-x}Mo_6S_8$ compounds are type II superconductors and hence an applied magnetic field can penetrate into their interior provided it is between the lower critical field value H_{c1} and the upper critical field value H_{c2}, above which superconductivity is destroyed. Under normal circumstances, the value of H_{c2} would be comparable with the paramagnetic limiting field value H_p. However, the $Eu_xSn_{1-x}Mo_6S_8$ compounds have magnetic moments associated with the divalent europium ions. Coupling between these magnetic moments and the conduction electron spins generates an 'effective' magnetic field, called the exchange field H_J, that acts on the conduction electron spins in the same manner as an applied magnetic field.

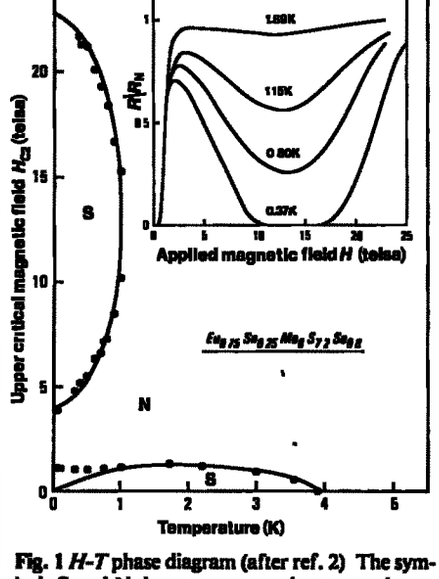

Fig. 1 H-T phase diagram (after ref. 2) The symbols S and N denote superconducting and normal regions, respectively. The solid circles represent the H_{c2} measurements of Meul *et al.*[2], the solid lines are the boundaries predicted by theory. Normalized electrical resistance, R/R_N, versus applied magnetic field data at several temperatures are shown in the inset.

If the sign of the coupling between the Eu magnetic moments and the conduction electron spins is negative, the direction of H will be opposite to that of H_J, that is, the effect of H_J will be 'compensated' by H (see inset to Fig. 2). The net magnetic field H_T is then given by $H_T = H - [H_J]$. The sequence of S-N-S-N transitions shown in the inset to Fig. 1 can be explained in terms of the relationship between H_T and H_p as illustrated schematically in Fig. 2. The upper and lower curves show the applied field H and the exchange field H_J respectively. Summation of these yields the net magnetic field H_T, and it is the variation in this with respect to the value of H_p that determines the superconducting behaviour of the material.

In zero applied field, the compound is superconducting. As the applied magnetic field is increased, the Eu magnetic moments become aligned in the direction of the field at a relatively low H-value and $|H_J|$ attains its maximum value $|H_J^{max}|$ of 30-50 tesla. Consequently, provided $|H_J|$ is greater than H_p, the magnitude of H_T (which is now negative) can become larger than H_p and drive the material into the normal state. As the applied magnetic field is increased further, the net magnetic field starts to decrease in magnitude, until its magnitude falls below H_p when the compound once more becomes superconducting. Thereafter, H_T increases linearly with H, vanishing and then changing sign at $H = |H_J^{max}|$ where H_J is completely compensated, until H_T (now positive) exceeds H_p, when the system once again becomes normal. Because the value of the exchange field can be rather large, the compensation effect can take place at very high magnetic fields.

In actuality, the second transition from superconductivity to normal state will also occur if H surpasses the orbital critical field H^*_{c2} of the compound. Thus, in order to observe MFIS, it is important that H^*_{c2}, which can also limit the value of the upper critical field H_{c2}, is large enough to allow superconductivity to occur in this magnetic field range (that is, $H^*_{c2} > |H_J^{max}| - H_p$), since the orbital effects are not compensated by the Jaccarino-Peter mechanism. The compensation of the exchange field by the applied magnetic field in several

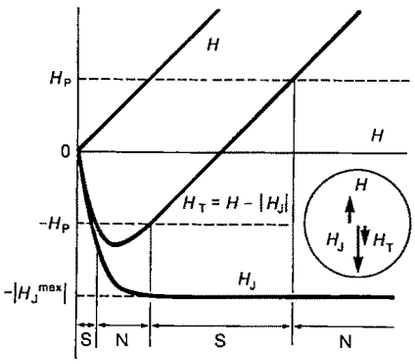

Fig. 2 Schematic diagram of the S-N-S-N transition sequence in an applied magnetic field H. H_T is the net magnetic field acting on the conduction electron spins, H_J is the exchange field produced by the Eu magnetic moments, and H_p is the paramagnetic limiting field. The material is superconducting (S) when $|H_T| < H_p$ and normal (N) when $|H_T > H_p$.

$Eu_xM_{1-x}Mo_6S_8$ systems (where M is a metal such as tin, lead, lanthanum[7] or ytterbium[8]) and in $EuMo_6S_8$ under pressure[9], had been inferred from an enhancement and anomalous temperature dependence of H_{c2} in these materials. Independent evidence for a negative coupling between the Eu magnetic moments and the conduction electron spins has emerged from the nuclear magnetic resonance and Mössbauer studies of Fradin *et al.*[10], electron paramagnetic resonance measurements by Odermatt[11] and the band structure calculations of Freeman and Jarlborg[12]. The phenomenon of MFIS was thus anticipated, but samples of the necessary high quality, in which the candidates for MFIS were satisfied, have not been available until the present study by Meul *et al*[2].

Following the initial suggestion by Jaccarino and Peter that MFIS could occur in a ferromagnet due to exchange field compensation, several theoretical investigations of MFIS in paramagnetic systems were carried out[13-15]. One model, based on the theory of type II superconductivity including the effect of the exchange field[14], was used by Meul *et al.* to analyse their $H_{c2}(T)$ measurements on the $Eu_xSn_{1-x}Mo_6S_8$ system. The calculated boundaries of the two superconducting domains observed for the compound $Eu_{0.75}Sn_{0.75}Mo_6S_{7.2}Se_{0.8}$ are indicated by the solid lines in Fig. 1 where the parameters of the theory (see ref. 2) have been adjusted to give the best fit to the data. The excellent description of the H-T superconducting phase boundaries shown in Fig. 1 within the context of the Jaccarino-Peter compensation mechanism can be regarded as singularly impressive. However, several important issues remain to be resolved before a complete understanding of this phenomenon can be attained. The behaviour of the superconducting energy gap and the flux-line lattice should be characterized, and the thermodynamic order of the magnetic field-induced transition needs to be estalished. It would, of course, be interesting to observe MFIS in other materials; preliminary evidence indicates that it may occur in the $Eu_xHo_{1-x}Mo_6S_8$ system[16].

Twenty-two years after its prediction by Jaccarino and Peter, MFIS due to the exchange field compensation effect seems to have been verified by Meul *et al.* on a paramagnetic system. But Jaccarino and Peter originally suggested MFIS in a weakly ferromagnetic material, assuming that it would be superconducting in the absence of ferromagnetic ordering. MFIS in a ferromagnet remains to be discovered. □

Hybrid oncogenes

A multi-purpose tool for studying multi-step processes

from Peter W. J. Rigby

INTRODUCTION of exogenous DNA into the mouse germ line is a well-established technique that has been applied to many biological problems. Most previous work has concentrated on the analysis of DNA sequences that mediate tissue- and cell-type-specific gene expression[1-7], but more complex biological phenomena can also be studied using this method[8,9]. Insertion of oncogenes, of either viral or cellular origin, into the germ line provides an *in vivo* system in which the mechanism of tumorigenesis can be analysed and is also likely to facilitate the study of development, differentation and cellular interaction. The paper by D. Hanahan on page 115 of this issue[10] describes the most interesting application of this approach so far reported.

Hanahan has constructed hybrid oncogenes in which the coding sequences of simian virus 40 (SV40) large-T antigen — a nuclear DNA-binding protein that can transform various cell types, including primary cells[11] — is placed under the control of DNA from the upstream region of the rat insulin gene[10]. Transfection experiments using cultured cells have shown that this region contains a cell-type-specific transcriptional control element that functions in insulinoma cells but not in fibroblasts[12]. Hanahan has used two types of construct: in one, the insulin upstream sequences are oriented so that the insulin promoter drives transcription of the T-antigen gene; in the other, the upstream sequences have the reverse orientation and so transcription of the viral oncogene cannot be driven by the conventional insulin promoter.

Lines of mice carrying each of these constructs in their germ line have been established. The mice develop normally but die prematurely at around nine to twelve weeks of age; before death their behaviour is normal. Immunological studies show that expression of large-T antigen is confined to the β-cells of the endocrine pancreas, indicating that the upstream sequences of the insulin gene are sufficient to confer cell-type-specific expression *in vivo* as well as *in vitro*. Proper expression occurs in mice carrying either construct; in the case of the inverted control region it is not known where the messenger RNA initiates.

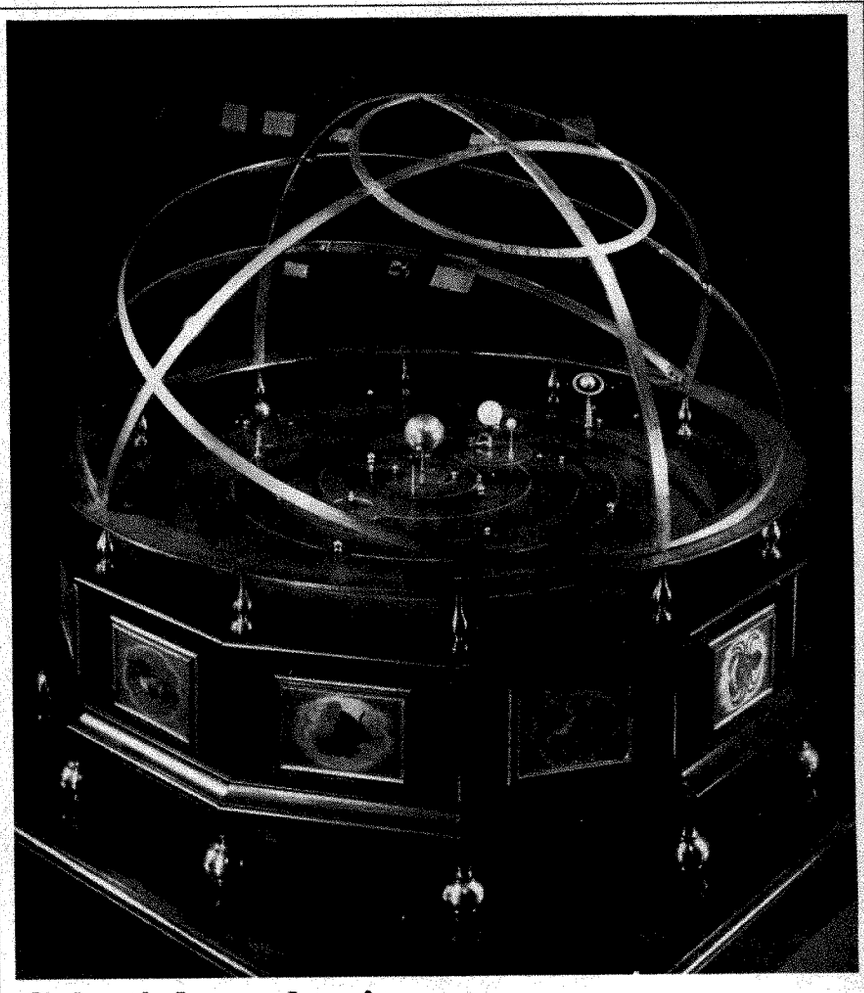
Histopathological and immunocytochemical analyses show that in young mice the islets of Langerhans are of normal size but that all of the β-cells express large-T antigen whereas the α- and δ-cells, which synthesize glucagon and somatostatin, respectively, are reduced in number and are disordered. With increasing age most of the islets become hyperplastic and are comprised almost entirely of β-cells expressing large-T antigen. Finally, a small pecentage of the hyperplastic islets give rise to well-vascularized β-cell tumours which do not metastasize.

Two other groups have recently developed lines of transgenic mice carrying oncogenes. In one study, the oncogene was again that encoding SV40 large-T antigen, but in this case expression was controlled by the virus's own promoter/enhancer region[13]. The mice develop normally but again premature death occurs, mainly as the result of tumours in a particular region of the brain, the choroid plexus. The other group constructed a hybrid oncogene in which murine c-*myc* encoding sequences were placed under the control of the promoter/enhancer in the long terminal repeat of the hormone-responsive mouse mammary tumour virus[14]. They observed expression of the hybrid oncogene in various tissues including the mammary gland and, most commonly, the salivary gland. In two

lines of mice, adenocarcinomas of mammary origin appeared in multiparous females at the time of pregnancy. The hormonal induction of expression that occurs in the lactating mammary gland is presumably prerequisite for the accumulation of sufficient levels of the c-*myc* oncogene product to induce the first step of tumorigenesis.

Although the *in vitro* experiments that suggest the existence of at least two classes of oncogene required for the transformation of primary cells[11-20] have aroused much interest, it is important to extend these findings to *in vivo* studies. Hanahan's results show that SV40 large-T antigen induces proliferation of the β-cells and the subsequent hyperplasia but suggest strongly that this is not sufficient to induce a tumour, otherwise all the hyperplastic islets would progress to tumours[10]. Similarly, tumours arise in only a few of the mammary glands of the mice carrying mammary tumour virus/c-*myc* oncogene. In these situations some second event must be required for tumorigenesis. An *in vivo* system in which the multi-step nature of tumorigenesis can be analysed has thus been established.

In vitro experiments are severely limited by the availability of suitable lines of cultured cells and by transfection efficiencies, whereas *in vivo* experiments allow expression of the oncogene to be targeted to any cell type for which an appropriate transcriptional control sequence is available. Large-T antigen could thus be expressed in many different cell types to ask whether the second event always affects the same gene or whether there is cell-type specifity for the subsequent events(s). Conversely, the insulin upstream region could be used to target the expression of other oncogenes to the β-cells to ask, first, whether hyperplasia and subsequent tumorigenesis are induced and, second, whether the subsequent event(s) is general, or specific to the initiating oncogene. Finally, two or more oncogenes could be targeted simultaneously to the same cell type. Such studies will greatly advance our understanding of the multi-step nature of oncogenesis. Equally important, they will enable molecular studies on tumour types for which there is no good *in vitro* model. The system should also make possible the study of processes, such as angiogenesis, metastasis and immune surveillance, that are hard to study *in vitro*.



It is curious that the β-cell tumours seem not to induce an immune response. SV40 itself is an extremely weak carcinogen in mice; tumours arise very rarely and with a long latent period[21,22], presumably because the small proportion of the large-T antigen that is displayed on the surface elicits a powerful immune response.

The severe disorganization of the other cell types in the endocrine pancreas induced by β-cell proliferation and hyperplasia is also of interest. The ability to perturb the growth of one cell type in complex interacting system will allow studies of the mechanisms that normally control the orderly growth and behaviour of an organ.

One further use of this type of study derives from the ability of many oncogenes, including those discussed here, to 'immortalize' cells. Thus, it may be possible to establish cell lines derived from all tissues of mice carrying such genes in their germ line. Indeed, it has already been shown that cells can be readily grown from a number of the tissues of the SV40 transgenic mice (A.J. Levine, personal communication). Such lines have considerable practical use. Commercial manufacture of some proteins may be limited by the inability of commonly used cell types to perform some post-translational modifications. The problem would be overcome if established lines of cells normally making the protein were available. □

Celestial mechanics

THIS fine example of an orrery, or mechanical model of the Solar System, is one of the early scientific instruments on display in the exhibition "Science and Profit in Eighteenth Century London" at the Whipple Museum of the History of Science in Cambridge until 6th December 1985. Orreries, used to teach the astronomy of the Solar System, were not made to scale but illustrate the relative positions and motions of the planets and their moons. This one, made by Geo Adams at Tycho Brahe's Head in Fleet Street, London, is calibrated for the Julian calender, which dates it before 1752. It includes Saturn with its rings and the five moons found between 1655 and 1684, but not Uranus, which was discovered only in 1781. Other instruments in the exhibition include an altazimuth theodolite, made about 1740, a compound microscope improved by tilting the limb for extra comfort, and a reflecting telescope.

Circadian rhythms

Period piece for *Drosophila*

from Kevin Moses and Michael Ashburner

NORMAL male fruit flies sing a courtship song to their prospective mates by vibrating their wings. There is a 20-50 ms interval between pulses of sound-and the length of this interval itself oscillates with a period of 50-60 s. This oscillation is under the control[1] of a genetic locus known as *period*, or *per*, which also plays a part in controlling the rhythm of locomoter activity of the flies. It is one of seven known genetic loci that determine the rhythm of eclosion, that is, emergence from the pupa, in a population of flies. The *per* locus was the first of the seven to be discovered, is still the best characterized and has recently yielded to molecular analysis by two groups, with fascinating, if not altogether consistent, results[2,3].

Genetic analysis of circadian rhythms of *Drosophila melanogaster* began with Konopka and Benzer's isolation of mutations affecting the eclosion rhythm[4]. Mutations of *per* can have a variety of effects on rhythm, which can become shorter than the normal 24 h — for example, 19 h in per^S flies; or longer — for example, 29 h in per^L flies; or arrhythmic — for example, in per^0 flies. Similarly, the 50-60 s oscillation in the period between bursts of love song in normal male flies is shortened to 40 s in per^S flies, lengthened to 80 s in per^L flies and absent in per^0 flies.

Thus, mutant alleles of *per* affect both circadian rhythms and much faster rhythmic activities. By transplanting brains between flies that differ in their genotype at the *per* locus, Handler and Konopka have shown that it is the expression of this gene in the brain that determines the fly's phenotype[5]. This suggests that the fly's behaviour is continuously affected by the expression of the *per* gene, a conclusion supported by studies with a temperature-sensitive per^0 allele (ref.6). The nature of the mutations that affect this rhythm is interesting. A complete absence of *per* function (as seen in a homozygous per^- deletion) gives an arrhythmic fly, but a partial loss of function gives a fly with a long cycle. This is the conclusion from the observation that females that are hemizygous for per^+ have a 25-h cycle.

For their molecular analysis of *per*, the groups from Rockefeller University[2] and Brandeis University[3] have used different starting points. The former cloned *per* by jumping from the previously cloned *Notch* gene, crossing the break points of a deletion that brought *Notch* just distal to *per*. From this starting point, they have characterized about 90 kilobases (kb) of contiguous DNA and by mapping the breakpoints of other chromosome aberrations to the DNA, have defined the *per* locus to a 25-kb interval. On the other hand, the group from Brandeis University microdissected polytene chromosomes to isolate DNA from band 3B1.2, which contains *per*, for cloning. Both groups have characterized transcripts in this region and have confirmed the cloning of *per* DNA by transformation.

Within the 25 kb of DNA that must, on genetic criteria, include the *per* locus, several transcripts have been identified. The two groups differ somewhat in their interpretation of the transcription data. Between the limits of two deletions that bracket the *per* gene the Brandeis group have found four transcripts, and the Rockefeller group three. Perhaps the most startling discovery by the Brandeis group is that the amount of the 0.9-kb transcript varies during the day: it is more abundant at 2 pm than 2 am. Furthermore per^0 flies have a greatly reduced amount of this transcript. The translocation *T(1;4)JC43* provides an interesting mutation of *per* because it acts as a per^0 mutation in eclosion assays but as a per^L mutation in locomotor-activity assays. This translocation has a correspondingly complex effect on transcripts from the *per* region, abolishing a 4.5-kb transcript, reducing the level of 1.1-kb transcript and producing two novel transcripts of 11.5 and 0.9 kb from the *per* region, according to the Rockefeller group[2]. The Brandeis group also finds two new transcripts (which they call 10 and 0.5 kb) and a reduction, but not a complete absence, of the 4.5- and 0.9-kb RNAs. Presumably the 0.9-kb Brandeis RNA and 1.1-kb Rockefeller RNA are the same species.

Unfortunately, the transformation data do not help to define the function of the *per* gene transcripts because the DNA used either did not include sequences that code for the cycling 0.9-kb RNA[7] or included the equivalent DNA but also the DNA that codes for the 4.5- and 1.0-kb RNAs[8]. The ambiguity results from the fact that all of the transformants remain mutant, with longer rhythms than normal. Whether this is due to a failure to obtain correct tissue-specific expression of the introduced *per* DNA, or whether the DNA lacks sequences required for normal *per* function, or is due to differences in the assay of the *per* phenotype, is unclear.

The fact that the two groups disagree as to the details of the structure and function of *per* should not detract from their achievements nor from the great interest in this gene. It is clear that we are now on the way to a molecular description of a gene whose function is required for both circadian and other rhythmic behaviours. □

Archaeology

Using isotope chemistry to detect prehistoric diets.

from Glynn Ll. Isaac

WHEN archaeologists seek to reconstruct the subsistence systems used by prehistoric hunter-gatherers, they face two particularly intractable problems. The first is to quantify the relative importance of plants versus animals in ancient diets, and the second is that of determining patterns of seasonal movements. Studies on bone composition have the potential to solve the second type of problem, as illustrated by the paper of Judith Sealey and Nikolaas van der Merw on page 138 of this issue[1].

In sites where organic remains are relatively well preserved, it is often possible, by patient study of the animal bones and shells, to rank the relative importance of different animal species as a source of food. Sometimes the same can be done for carbonized plant remains. However, it is seldom possible to gauge the proportions of plants and animals relative to one another. Similarly, while particular remains can sometimes allow archaeologists to say that a site was occupied during one season, it is often much harder to be sure that the site was *not* occupied in other seasons. So, having found a few sites with complementary seasons of apparent occupation, is it safe to link up these observations and infer a patterned seasonal round of movements by the occupants?

During the 1960s and 1970s, the seasonality issue was dramatized by the writings of a Cambridge school of economic prehistorians inspired by Grahame Clark and led by the late Eric Higgs. In effect, Higgs suggested that the most efficient use of many landscapes would have involved sweeping seasonal movements of inhabitants and livestock. The model was (and is) attractive, but how was its applicability to particular pieces of prehistory

to be tested? Did hunter-gathers maximize their foraging? What effects might the packing of several social groups into a landscape have on the feasibility of seasonal movements? These are questions of interest and importance in archaeological modelling of prehistoric ecology, but in very few cases has it been possible to obtain evidence to test intuitive answers.

Fortunately, archaeologists are optimists who continue to pursue their enquiries Micawber-like, and in the last few years they have been rewarded. It has emerged that to some extent humans are what they eat. Diet affects the composition of bone in various ways and subtle signals, indicative of various aspects of the subsistence regime, may be preserved in prehistoric skeletons. For instance, in any given region the calcium to strontium ratio at the time of death can be used to separate pure herbivores from pure carnivores and to establish a scale of mixed diets[2,4]. In addition, the carbon-13 composition of bones can serve as a measure of the relative dietary contribution of C_3 and C_4 plants; for example, the spread of maize into the woodlands of North America has been monitored in that way[5,6]. Nitrogen isotopes, along with carbon isotopes, are providing measures of the relative importance of seafoods and legumes in some ancient diets[7-9].

Thus, in recent years, aspects of stable isotope chemistry and human bone biology have become important in studies of prehistoric subsistence systems, such as that reported by Sealy and van der Merwe in this issue[1]. Their investigation took as its starting point what must surely rank as one of the most sustained and informative archaeological studies of regional hunter-gatherer subsistence and land-use patterns, carried out over some fifteen years by a group at Cape Town University led by John Parkington[10]. It has monitored responses that span a sequence of environmental change starting 20,000 years ago. Amongst other things, Parkington suggests that there existed at some stage a strong pattern of seasonal migration of human groups between the coast and an inland range of mountains. A series of sites with evidence of complementary seasons of occupation make the model plausible and attractive. But is it correct?

Sealy and van der Merwe report an ingenious and painstaking investigation of bone composition, which they use to explore the question of seasonal movement. Extensive measurements of a full range of coastal foods show that they have markedly different carbon-13 abundances from a full range of mountain foods (be they plant or animal). From this, it is possible to predict the isotope content of bones from people on a coastal diet, a mountain diet or the mixed diet that would indicate seasonal migration between the coast and inland mountains. Tested against the predictions, the compositions of bones do not sustain the hypothesis of extensive seasonal migration of the same people between the two habitats.

Although the results hold out promise that bone-composition studies will sometimes provide otherwise unavailable information about prehistoric ranging patterns and the use of food from different ecozones, the findings in this particular case must be seen as provisional. The samples of skeletons from each time period and each zone are small and need enlarging. Careful alternative modelling of various mixed diets will also need to be considered. Nevertheless, the patterns seem consistent enough to be highly suggestive that, attractive though it may have seemed even then, spending summer in the Alps and winter on the Riviera was not always feasible in prehistoric times. □

Meterology

What limits front formation?

from K.A. Emanuel

FOR many years, meteorologists and oceanographers were perplexed by the tendency of fluid flows to form 'fronts', or near discontinuities, in such properties as temperature, salinity gradients and velocity. These fronts, which occur in both the atmosphere and oceans, seem to defy the general tendency of turbulent flows to smooth out strong gradients of fluid properties. Then, in 1972, B.J. Hoskins and F.P. Bretherton (*J. atmos. Sci.* **29**, 11; 1972) developed an attractive theory which clearly explained the dynamics of front formation and which predicted the formation of real discontinuities in density gradients and velocity. This presented meteorologists with a new problem: why do actual fronts consist of zones of strong gradients, spread out over horizontal distances on the order of several tens of kilometres, rather than of real discontinuities?

It is natural to suppose that turbulent mixing limits the gradients found in real fronts and, until recently, it was assumed that the mature frontal zone represents a balance between the dynamics of front formation and their dissipation by turbulence. Recently, however, I. Orlanski and B.B. Ross (*J. atmos. Sci.* **41**, 1669; 1984) have suggested that frontal collapse may be at least partially limited by processes that do not involve turbulent mixing. Their conclusions stem from the results of numerical simulations of atmospheric fronts, making use of the full equations that describe the conservation of momentum, heat and mass, rather than the approximate forms used in the Hoskins-Bretherton model.

These approximate equations, which can sometimes be solved analytically and which have proved extremely useful in advancing the conceptual picture of front formation, are based on an assumption of cross-front geostrophic balance — that is, forces arising from pressure gradients across the front are assumed to be balanced by Coriolis accelerations acting on the component of wind parallel to the front. This approximation can be shown to be valid during most of the time it takes for density gradients to collapse but it eventually breaks down near the time of formation of discontinuities. When this happens, the cross-front pressure gradient force may be balanced by actual particle accelerations across the front as well as by Coriolis accelerations. The numerical simulations carried out by Orlanski and Ross seem to show that these effects tend to limit rate of front formation, at least, and perhaps also the ultimate amplitude of the cross-front gradient of front-parallel velocity.

As Orlanski and Ross point out, an exact interpretation of the numerical simulations is problematical. It is generally necessary to represent some turbulent mixing to keep the time integration stable, and it is not clear what role this diffusion plays in limiting the numerically simulated fronts. Detailed evaluation of the dynamics of the simulated fronts is also hampered by the finite horizontal resolution of numerical models. (In this case, the horizontal distance between grid points is 61.5 km.)

Finally, it is well known that near discontinuities can form in non-rotating fluids in which the balance in the frontal zone involves no Coriolis accelerations; taken together with present results this implies that, while both purely inertial and purely geostrophic fronts are limited by turbulent mixing, fronts involving both inertial and Coriolis accelerations may be limited by a non-diffusive mechanism.

This non-intuitive idea, if true, presents a startingly different view of the dynamics of mature fronts in the atmosphere and oceans. More work with numerical models and better observations of frontal zones should help assess its validity. □

Bacterial immunology

Antigenic variation in gonococcal pili explained

from J.R. Saunders

ANTIGENIC variation of surface structures in pathogens is an important mechanism for avoiding host defence mechanisms. *Neisseria gonorrhoeae*, the causative agent of gonorrhoea, is well known for its ability to exhibit interstrain and intrastrain variation in the type of pilus (fimbria) that it produces. Pili — hair-like proteinaceous structures — are important virulence factors in gonococci because they mediate adhesion of the bacterium to mucosal surfaces during the initial stages of infection. Variability in such exposed surface structures goes some way to explaining the success of this bacterium in causing repeated infections in humans. On page 156 of this issue, Per Hagblom and coworkers have shown that pilin, the protein subunit of gonococcal pili, consists of constant and variable regions with the amino-terminus being conserved and the carboxy-terminus containing more-or-less variable amino-acid sequences[1]. They propose that antigenic variation in gonococcal pilins can be explained by chromosomal rearrangements that result from intragenic recombination between a repertoire of cassettes of different pilin genes[1,2].

Gonococcal pili are composed of identical pilin subunits of relative molecular mass 18,000-22,000, with apparent relative molecular mass and antigenic differences depending on the protein strain involved. The 53 or so amino acids at the amino-terminus of the polypeptide are conserved in all pili from *N. gonorrhoeae* and constitute a constant region[1,3]. The remaining 100-110 amino acids that form the carboxy-terminus of the protein are variable and account for the antigenic diversity observed within and between strains. This variable region can be divided into two domains, a semi-variable region that extends between amino-acid residues 54 and 114 and contains many different amino-acid substitutions depending on the pilin examined, and a hypervariable region that extends from residue 115 to the carboxy-terminus and contains deletions as well as substitutions and insertions of 1-4 amino acids in different pilin variants[2]. Immunological and sequence studies suggest that the hypervariable region is itself flanked by short (about 10-residue) regions of conserved amino-acid sequence that centre around the cysteine residues at positions 121 and 151 (refs 1,4). Polyclonal antibodies raised against purified pili are primarily directed at antigenic sites that lie within the disulphide loop formed between these cysteine residues[4]. The constant region seems to contain a much more weakly immunogenic epitope(s) that is common to all gonococcal pili.

Antisera raised against synthetic peptides corresponding in sequence to residues 41-50 in the constant region and residues 69-84 in the semi-variable region of pili from *N. gonorrhoeae* strain MS11 are effective in inhibiting the binding of heterologous gonococci to human cell lines[4]. In contrast, monoclonal antibodies directed against the variable, type-specific hypervariable domain, but not the conserved domain, are able to block binding of purified whole pili from *N. gonorrhoeae* strain P9 to animal cells[5]. These findings suggest that components of both conserved and variable regions are involved in binding to cell receptors because of the way that the mature pilin polypeptide is folded.

Appropriate synthetic peptides, either singly or in combination, might be useful as components of vaccines directed against gonorrhoeae. Such vaccines would work by eliciting antibodies that would prevent adhesion of the pathogen to the epithelial surface. The immunodominance of the variable part of pilin molecules and the many immunologically distinct pili that can be assembled by just one strain of the gonococcus may compromise such an approach.

Variability in piliation of *N. gonorrhoeae* involves two distinct genetic phenomena. In the first, pilus phase variation, pilin genes are reversibly switched on (to produce piliated or P^+ cells) or off (to produce non-piliated or P^- cells) at a high rate. The second process, antigenic variation, involves the generation of biochemical and antigenic diversity in pilus type and is caused by the expression of alternative pilin genes. The two processes are probably closely linked as the transition between P^+ and P^- states is accompanied by genome rearrangements; P^- derivatives that switch back to the P^+ state frequently express pili that are antigenically distinct from those produced by the original P^+ strain[1-3].

The ability to alter piliation status by a phase change is of great advantage to this pathogen because, although they are important adhesions for initiating infection, the pili might render the organism more susceptible to host defence mechanisms once access to tissues has been gained. It is also not yet clear whether the genetic mechanism for antigenic variation requires phase variation to the P^- state as an obligatory intermediate stage. Pili are major surface antigens in the gonococcus and, therefore, frequent changes in their antigenic nature may assist in avoiding host immune responses. Variations in pili may also be associated with differential attachment to, and virulence for, animal cells, suggesting that one role of antigenic variation is to allow sequential adhesion to different cell types during natural infection[5].

The chromosome of *N. gonorrhoeae* strain MS11 contains two expression loci, *pil*E1 and *pil*E2, involved in production of pilus protein and located within about 26 kilobases of each other on the chromosome[3]. When cells are in a piliated state both these genetic loci carry intact pilin coding sequences as well as their own promoters. Phase variation from P^+ to P^- states involves deletion of pilus-coding sequences from one or both of the expressing loci[2]. Deletions in *pil*E apparently involve single or multiple recombination events between directly repeated sequences that lie within these loci. Interestingly, deletion in only one *pil*E gene can result in reduced or no pilus expression despite the fact that the remaining gene is apparently intact and should be functional. This suggests that there is a further mechanism (possibly a *trans*-acting activator) for regulating pilus expression that is itself regulated by the recombinational switching events.

It is not yet clear whether pilin sequences deleted from *pil*E are destroyed, as occurs in yeast mating-type conversion, or whether they are parked in silent, non-expressing loci somewhere else on the gonococcal genome, as occurs in antigenic variation of surface glycoproteins among certain trypanosomes. Certainly the ability of a P^- derivative to switch back to producing homologous pili suggests that the information necessary to produce a specific pilin is conserved. However, a functional expressing gene can be regenerated by recombination between a deleted *pil*E1 and an intact *pil*E2 locus[2]. This may be part of the reason for the duplication of *pil*E in the gonococcal genome, although maximization of pilus expression and the potential to elicit two distinct pilins simultaneously may also be involved.

The chromosome of the gonococcus contains, in addition to the two *pil*E loci, several silent sequences (*pil*S loci) that are partially homologous to the expressed pilin genes but which lack their own promoters[2,3]. One such silent locus, *pil*S1, lies within about 15 kilobases of *pil*E1 and contains sequences that are not colinear with the mature pilin coding sequence.

Sequences corresponding to the variable part of pilin are over-represented in *pil*S by about 15-20 times compared with those encoding the constant part[3]. This suggests that the silent regions contain information necessary for generating antigenic diversity. Furthermore, regeneration of intact pilin-expressing loci during a P^- to P^+ phase change can be explained by gene-conversion events that would result from recombination between a *pil*S locus and a partially deleted *pil*E site[1,2].

What is not yet clear is whether *pil*S1 or some other more remote silent locus is the active donor of DNA sequences corres-

ponding to the variable part of pilin. The enzymatic mechanism that effects the required intragenic recombination events is also unknown. It will be interesting to discover whether specific enzymes exist for this purpose or whether the normal generalized recombination system of the gonococcus is sufficient.

It should be remembered that pili are only one component of a complex armoury of virulence determinants expressed by the gonococcus. One such determinant is principal outer membrane protein II (PII or Op), which also undergoes both a phase change and antigenic variation. Interestingly, *opa*, the structural gene for this protein, is located within 1 kilobase of *pil*E1, although the two genes do not seem to be coordinately regulated nor are gross genome rearrangements involved in the modulation of expression[6].

The genetic mechanisms used by *N. gonorrhoeae* for alteration of pilus type have parallels in other parasites that exhibit antigenic variation and in processes such as the generation of immunoglobulin diversity. Much of the evolutionary success of this pathogen, which has no host other than man, may be attributed to its complex devices for ensuring variation in its major surface antigens. □

Polar studies

History of an Antarctic lake

from David A. Peel

DESPITE its immense ice-cap, Antarctica is in fact a polar desert where extremes of cold and aridity have created several unusual features. Since the earliest days of exploration, scientists have been fascinated by more than 20 ice-free areas or oases, which are now known to occur where local weather conditions determine that the overall rate of ice sublimation from the surface exceeds the annual rate of snowfall. These areas are completely free of ice providing that local geographical barriers prevent ice flow from a neighbouring area where it is accumulating. Within these dry regions, perennially ice-covered lakes are fairly common, but in many cases satisfactory models of their histories and physical characteristics have yet to be developed. On page 131 of this issue, Hermichen *et al.*[1] present new isotope data from a large freshwater lake in East Antarctica and demonstrate that the present-day lake is the concentrated residue of a body of water originally more than 50 times larger.

The perenially ice-covered lakes of the Antarctic show some unusual chemical and physical properties[2]. Normally highly saline, although basically of freshwater origin, they occur in areas where the mean annual air temperature is around minus 20°C. They are usually covered by a relatively thin layer of ice overlying water which is at least 20°C, and sometimes up to 50°C, warmer than their surroundings. As the occurrence of life depends on the presence of liquid water, the lakes have been a focus of interest for biologists seeking to understand the adaptation of organisms to extremes of temperature[3]. Although the general morphology of the lakes has been understood for some time, they are individually a result of often quite complex histories.

One basic physical characteristic that has a direct bearing on the biological productivity of a lake, the thickness of the ice cover, has been modelled recently[4]. It has long been known that for lakes that are not frozen to the bottom, the ice thickness is relatively constant from place to place despite wide variations in the temperature and chemistry of the water. More than two decades ago it was suggested[5] that solar heating was probably the main source of energy for the Antarctic lakes, with a skin of exceptionally transparent ice at the surface of the lake acting rather like greenhouse glass. Each summer, melt water flows into the lakes beneath the ice, balancing water lost by evaporation from the ice on the surface. Under steady-state conditions, it has been suggested that each winter a thickness of ice freezes onto the base of the floating ice, generating latent heat which balances the loss of sensible heat through the ice cover.

McKay *et al.*[4] have recently developed a simplified model of the energy balance at the surface of Antarctic lakes based on analysis of annual average heat fluxes. The thickness of the ice cover is apparently sufficient to damp out most of the seasonal variations in the fluxes of heat from sources and sinks. Using actual measurements of solar flux and albedo values from one of the best-studied lakes (Lake Vanda, southern Victoria Land), and direct measurements of the typical light-transmission characteristics of the ice, these authors have been able to predict the equilibrium ice thickness as a function of the surface ice ablation rate. They found that this rate of ablation is the prime control of ice thickness; measured ablation rates of around 30 cm per year lead to predicted equilibrium ice thicknesses in the range of 3-4 m, in good agreement with what is observed. Lakes at higher altitudes lie closer to the snow line and suffer less ablation; moreover, the ice is often anchored to the bottom and hence the latent heat contribution from refreezing melt water ceases to be an important factor. In these lakes much greater thicknesses of ice can be maintained under a given air-temperature regime.

Analysis of the stable isotope composition of lake waters has proved to be a valuable tool in deciphering the evolution of present-day water systems[6]. Lake Untersee, the subject of the study by Hermichen *et al.*[1], was first probed by a Soviet team in 1969. The lake has an area of about 10 km^2 and lies in an region of high ablation (about 20 cm per year). Refreezing of melt water supplied by the adjoining glacier leads to an equilibrium ice cover which is 2.5 m thick. It is difficult to envisage how such a large volume of fresh water could have accumulated under present-day climatic conditions (the average temperature is roughly minus 20°C). Both the stable isotope data and the lack of any evidence for modern tritium indicate that the water has originated from the melting of old glacier ice. In this case, the concentration of salts in the relatively saline water now found can be accounted for if the present-day body of water is the residue resulting from the evaporation of a volume originally more than 50 times larger. The new isotope data provide some additional support for this idea. The present-day water is isotopically lighter than the snow that currently falls in the catchment area of the lake. Furthermore, the composition with respect to the Meteoric Water Line (a steady relationship between $\delta^{18}O$ and δ^2H generally observed in atmospheric precipitation, which reflects mainly equilibrium fractionation of the isotopes) is displaced in the direction of preferential depletion of ^{18}O. Both results can be explained satisfactorily if it is assumed that the water has been lost from the lake by sublimation of ice from the upper surface. The isotope composition of the sublimating water is then determined by isotope exchange during the freezing of water where ^{18}O is preferentially deposited. The indications are that this process has been proceeding more or less continuously since a period of warmer climate in the early Holocene. There are signs of biological primary production in Lake Untersee; future studies of organic deposits on the lake bed may help to trace the lake's evolution. □

Why should plants be evergreen?

SIR — I read with interest Peter D. Moores's article "Why be an evergreen?" (*Nature* **313**, 703;1984). One factor referred to as a possible explanation for leaf longevity was leaf fall as a potential sterilizing agent. It was stated that many evergreens grow in impoverished soils. It has been argued in the past that plants growing in these conditions need to invest more heavily in chemical protection against phytophagous insects since growth on poor soils is slow, increasing vulnerability to attack. Many evergreens appear to be particularly rich in chemicals which defend them from phytophagous insects (terpenes associated with pine, for example). On the other hand, where growth is less costly, the alternative defence against phytophagous insects may be simply to shed leaves synchronously — that is, to adopt the deciduous habit to cleanse the tree annually of pests.

This hypothesis is open to an experimental test. If an evergreen is fumigated to remove phytophagous insects at the same time a deciduous species is coming into leaf, phytophagous insect population growth, measured as insect biomass per tree biomass, should be more rapid on the latter than the former. A favourable result would, however, be indicative rather than conclusive support of the hypothesis.

The hypothesis would be suspect if the maximum insect biomass achieved per tree biomass were higher on the evergreen. The reverse of this result would be consistent with the hypothesis whereas similar maxima would be the least informative outcome (although not inconsistent with the hypothesis).

Assessing the risk of dioxin exposure

SIR — The health risk of exposure to 2,3,7,8-tetrachlorodibenzodioxin (dioxin) is a subject of considerable international interest which has been addressed recently in *Nature*[1] and *Science*[2,3]. As noted many times, understanding the nature of risk to humans is difficult because of the relative lack of information from epidemiological studies. Because of this, great emphasis has been placed on the results of two papers drawing on the mortality experience of workers exposed to dioxin at the Monsanto chemical plant in Nitro, West Virginia[4,5].

As with many occupational health studies, there are problems with these papers in the definition, and consistency of definition, of exposure. Zack and Suskind[4] report nine cancer deaths in the cohort of 121 workers exposed to tetrachlorodibenzodioxin in a specific trichlorophenol process accident, occurring in 1949. These nine deaths (Table 2 in the paper) give details of the individual's year of birth, year of hire by Monsanto, year of death and the cause of death. In the second paper, by Zack and Gaffey, published three years later[5], there are lists of death from cancer amongst workers at Monsanto who are described as having been exposed to the herbicide 2,4,5-T. Workers exposed to 2,4,5-T were also exposed to varying concentrations of dioxin and were classified on the basis of having contracted the sentinel indicator disease chloracne. Zack and Gaffey report 25 deaths from cancer in the controls, workers not exposed to 2,4,5-T. This is referred to in Table II of the paper[5].

In comparing the two papers, some men are listed as exposed to dioxin in one paper, but as not exposed in the other. In Table 2 in the Zack–Suskind paper, four cases are described as exposed to dioxin, whereas in the Zack–Gaffey paper, Table II reports the same four being not exposed (to 2,4,5-T and dioxin). Cases 1,2,5 and 7 in the Zack–Suskind Table 2 are those listed as being exposed to dioxin whereas in Table II of the Zack–Gaffey study, the same individuals are described (lines 6,7,9 and 22 of table) as being non-exposed. Judith Zack, an author on both papers, has reported that these individuals are one and the same[6].

In addition, a number of exposed individuals may not have been included in the second Monsanto study. In Monsanto records, there are some 19 individuals who died of circulatory disease or cancer whilst in employment at the company, and who meet the criteria for inclusion in the exposed group. No reason is given for not including these cases.

Determining exposure in the context of the Nitro plant is clearly difficult, since conditions may have produced general exposure to much of the work force. Those men exposed to the chemical in the 1949 trichlorophenol process accident are said to have been seriously exposed, on the basis of developing more severe chloracne, than the men exposed to dioxin in the course of making 2,4,5-T over several decades at Nitro. It may be the case that some of the more severe chloracne cases were the workers exposed to dioxin in the trichlorophenol process accident. However, there was a similar spectrum of chloracne incidence in both groups according to a study in 1953[7]. Of the 117 cases of chloracne determined in 1953 in individuals exposed to dioxin as a result of the 1949 accident, 10 workers had left the company, 80 were said to have recovered from the skin disease, 24 had a mild form of chloracne, and 3 had moderately severe disease. In other workers exposed during 2,4,5-T manufacture, 97 additional cases of chloracne were reported as having occurred, 51 of these cases were regarded as being clear of the disease, 36 were said to have a mild form and 3 to have moderately severe skin disease. Seven of the 97 men had left the company. Thus the spectrum of chloracne in the two groups seems similar. Another reason why it is inappropriate to separate these two exposed groups comes from information from a former manager of the Nitro plant[8]. In his deposition to court, Durland reported that some of the same workers were involved both in the clean-up after the trichlorophenol reactor accident and in making 2,4,5-T.

It may not be appropriate to classify degrees of dioxin exposure solely on the basis of chloracne as an indicator of relatively acute high-dose exposure to certain chlorinated hydrocarbons, including dioxin[9]. Other health effects — notably serious diseases of long latency, such as cancer — may be expected to result from lower and more chronic exposure[10-13]. Using one outcome variable to predict others is not advisable. Occupational studies usually use work histories, biological monitoring, or environmental measurements to determine, or approximate, exposure of subjects.

In view of the importance of the Monsanto cohort for determining human health risks of dioxin, it is our view that data from the company need to be reassessed. The *total* cohort of workers exposed to dioxin at Monsanto should be considered as a whole without making a distinction, as apparently done by Suskind, Zack and Gaffey, between workers exposed to dioxin in the trichlorophenol process accident or when making 2,4,5-T.

It may be that the overall number of deaths — from cancer, circulatory disease or other causes — is no greater than an appropriate control cohort. Data from a recent study by Moses *et al.*[14] on this same population suggests that there is an excess of cardiovascular-related deaths[15].

The epidemiological picture at Monsanto remains confused. We believe that more information will only be established by re-examining all of the data, and, given international concerns over dioxin, that this needs to be done urgently.

Dosage compensation and X-chromosome inactivation

SIR — It is now common practice to use the terms dosage compensation and X-chromosome inactivation interchangeably. It is argued here that this equation is technically incorrect and, more importantly, that it obscures a nontrivial facet of mammalian physiology. The proposition is that in flies and mammals, dosage compensation allows males to survive their monosomy for the X chromosome. In mammals, X inactivation is then a device that prevents females from expressing a tetrasomic level of X-chromosome gene product. That is, X inactivation allows females to survive dosage compensation. If we call X inactivation dosage compensation, we are overlooking something in males. That something is dosage compensation.

The idea of dosage compensation and its definition originated with H.J. Muller in his studies of *Drosophila*[1]. In the context of the issues of his day, Muller saw dosage compensation from a selectionist perspective concerned with optimal phenotypes. In this view, dosage compensation was the mechanism by which selection has achieved equality of expression of sex-linked genes in single-X males and two-X females. In the modern context, however, we are forced to add an element to the Mullerian view: dosage compensation not only equilibrates male to female phenotypes but also — and perhaps primarily — equilibrates a male's single X to his two sets of autosomes. The point we seem to overlook is that a *Drosophila* male (or the heterogametic sex in any organism with a chromosomal sex determination system) is aneuploid and aneuploidy is deleterious.

We know from an extensive study of aneuploidy in *Drosophila*[2] that any heterozygous autosomal deficiency greater than about 3% of the haploid genome is a lethal condition. On the other hand, a *Drosophila* male is deficient for a whole X chromosome (about 20% of the genome). The issue, then, transcends his similarity to his sister. He requires dosage compensation for his survival. In *Drosophila melanogaster*, dosage compensation is effected by the elevation of the rate of transcription of the lone X in males relative to either of the X chromosomes in females[3-5]. More to the point, mutations in *Drosophila* which fail to hypertranscribe the X chromosome in males are male-specific lethals[6].

Aneuploidy in mammals, as in *Drosophila*, is deleterious. Mammalian males, like *Drosophila* males, have a congenital aneuploid condition for a considerable fraction of their genomes. We infer that dosage compensation in mammals, as in *Drosophila*, balances the expression of the single X chromosome in males to the autosomal complement; that is a male's single X is hypertranscribed relative to his autosomes. Hypertranscription in *Drosophila* males presents no problem for *Drosophila* females, as they transcribe their two X chromosomes at a basal rate balanced to the autosomes. However, in a species in which X hypertranscription is a property of all X chromosomes in either sex, the female has become, in a formal sense, a hyperploid. Since hyperploidy is also a deleterious condition, she would require a second system to achieve X to autosome balance. One option is to inactivate one of the two X chromosomes.

If mammalian X chromosomes are hypertranscribed in the interest of male survival, X-chromosome inactivation must be dosage-compensation compensation in the interest of female survival. This inference may be of some heuristic value in that it implies the existence in mammals of a class of genetic elements which function to modify X-chromosome expression and to which we might want to give some thought.

High time for psychoimmunology

SIR — The term "psychoimmunology" was coined by Solomon[1] to describe his early studies of the effects of behaviour on immune function and on susceptibility to certain experimentally-induced disease processes. More recently, "psychoneuroimmunology"[2] has been used to refer to studies of the neuroendocrine mechanisms mediating the effects of behaviour on immune function — and vice versa. But in a News and Views article, "Psychoimmunology before its time", John Maddox questions the explanatory potential and, by implication, the heuristic value and practicality of pursuing such research[3].

Despite an erroneous characterization of what is "psychosomatic", the article correctly implies that much of the impetus for studying interactions between the central nervous system (CNS) and the immune system derives from observations that psychosocial factors influence the development and progression of disease. To phrase this as a "familiar theme in literature", however, is to impart a scientific triviality to such phenomena. In fact, there is a voluminous scientific literature that documents the integration of mind and body. To justify this scepticism, Maddox points out that the mechanism for such phenomena is unknown, but this does not mean it is unknowable — or that the phenomena are less real. In an attempt to account for such phenomena, then, it is quite reasonable to hypothesize that changes in immune function may mediate the effects of psychosocial factors on the development and/or progression of some pathophysiological states. Such a hypothesis is tenable, however, only if it can be shown that the CNS plays some role in the modulation of immunity.

In referring to a *kind* of connection that is made *plausible* by several unconnected observations, the article begrudgingly acknowledges a functional relationship between the CNS and the immune system. This is not the common knowledge that it is implied to be. That it is accepted at all is, in large part, a result of psychoneuroimmunological research conducted over the past 10 years. The scepticism expressed in the article, however, is not directed at the experimental findings of psychoneuroimmunology. It is fabricated, instead, out of unreferenced claims attributed to "psychoimmunologists": we know of no serious investigators who "talk as if there is no state of mind which is not faithfully reflected by a state of the immune system". The hypothesis that a behavioural state may have immunological consequences, however, cannot be dismissed as easily. After all, there are neurophysiological and neuroendocrine consequences to behaviour and accepting a link between the CNS and the immune system, it would be reasonable to expect that influences are exerted in the opposite direction. Analyses of the interactions between behaviour and the immune system are not a traditional part of either immunology or the behavioural or neurosciences, but perhaps they should be.

Space does not permit us to do more than point to the article's superficial analysis of the studies by Laudenslager *et al.*[4] and Schleifer *et al.*[5], the evaluations of research based on the time consumed and its cost, the false analogy between the (unreferenced) claims of psychoimmunologists and attempts to link states of mind with the development of cancer, or the difficulty of conducting psychoneuroimmunological research and the implication that the results obtained are neither reproducible nor significant. The basic flaw in the argument is revealed by what is claimed to be a crucial unanswered question: if a person's affective response to some event is capable of influencing immune function, why, the article asks, would such a person be more likely to die of a heart attack or even an automobile accident?

This question is not crucial; it is not even relevant. The relationship between an affective state and immune function may be

quite independent of the relationship between that affective state and other physiological processes and, in any case, depends upon a myriad of other biological and environmental factors. Furthermore, such a question could follow only from the underlying assumption that behaviourally-induced alterations in immune function represent the single mechanism by which psychosocial factors influence disease. We know of no psychosomaticist or psychoimmunologist who would accept such a proposition and we cannot imagine how such a hypothesis could be derived from the available literature.

There are probably those in every field whose exuberance outdistances their data. One is not required to share their exuberance, but one is obliged to consider their data. One can only wonder, then, why anyone would want to throw out the baby with the bathwater. Connections between the CNS and the immune system are now being uncovered. Whatever forces were operating to set immunology apart, recent data suggest that much could be learned by studying immunoregulation as part of an integrated network of adaptive processes including behaviour. If not now, when?

JOHN MADDOX WRITES — My article was a protest against those psychoimmunologists who attribute as yet unwarranted importance to the immune system (as distinct from other physiological systems) among the physiological correlates of behaviour. My statement that "people may be driven by adversity into decline is a familiar theme in literature" was not intended to demean psychoimmunology but, rather, to illustrate that the phenomena it seeks to account for have long been recognized.

My reference to heart attack and road accidents rather than, say, infection among the causes of death of those who have been psychologically shocked was intended to raise the precise question Ader and Cohen answered by saying that physiological systems other than the immune system may be involved.

I see nothing objectionable in the moderate statement of Ader and Cohen. Specifically, I can readily accept that there are many immunological consequences of, say, bereavement, although I do not believe that the tendency towards untimely death among bereaved spouses can be attributed primarily (or even at all) to the immune system (which is not to say that that may not be an attractive speculation).

Underlying this dispute (which seems to me not to be a substantial disagreement) is an important question. These reductionist days, it is proper to seek to identify the mechanisms by which states of mind cause physical illness. The immune system is one candidate, perhaps the most obvious after the adrenal hormone complex. But we all know that Freud's place in intellectual life rests in part on his careful documentation of the phenomena of psychosomatic illness, and on his explanation in terms of the unconscious, nowadays a somewhat old-fashioned concept.

So what if further investigation should show that the nervous system, and especially that part of it within the skull, plays an important part in the causation of psychosomatic illness? Such a development would no doubt be hailed as an important step towards Freud's rehabilitation, as a prophet if nothing more.

The point of this speculation, in the present context, is not to say that that is how it will turn out, but simply to suggest that the less obvious fields for explanation may ultimately be more productive. Much of the abuse that reductionists have recently attracted stems from their weakness for the kinds of explanations which happen to be at hand. □

An unexpected result in classical electrostatics

SIR — A recent discussion of the structure of snowflakes (W.S. Mortley, *Nature* 313, 638; 1985) mentions the possible role of electric forces. In this and similar problems, establishing the least energy configuration appears vital. I would like to draw attention to a surprising result, which, to my best knowledge, has not been mentioned earlier.

What will be a minimum-energy configuration of a system of N equal point charges q placed inside a circle?

At first glance the answer is obvious: the Coulomb repulsion will arrange all N charges at the vertices of a regular polygon inscribed into the circle (configuration A). This statement seems to be so obvious that, apparently, nobody bothered to verify it by a direct calculation of the total electrostatic energy of the system (W). However, such calculation, which can be easily performed on a programmable pocket calculator, shows, rather surprisingly, that this is true only for $N < 12$. In units q^2/R the total Coulomb energy W is equal to 48.57568 for $N = 11$ and 59.80736 for $N = 12$. An alternative configuration (B), which is also compatible with the total symmetry of the system, has $N - 1$ charges equally spaced along the circumference and one 'extra' charge at the centre of the circle. For $N = 11$, $W(B) = 48.62450$ (that is, greater than $W(A)$), but for $N = 12$, $W(B) = 59.57568$, that is, less than $W(A)$. The non-equality $W(B) < W(A)$ also holds for $N > 12$ (I verified this numerically to $N = 400$, but very likely it is true for any $N > 11$).

The above result means that starting from $N = 12$, the second configuration B (with one charge expelled to the centre of the circle) takes over from A as the minimum-energy configuration. In other words, it will be energetically beneficial for the system of N equal point charges confined in a circle to 'expel' one charge to the centre of the circle (if $N > 11$). Similar effect (the 'spontaneous ejection' of one charge to the geometrical centre) will also be likely to happen for N charges inside the spherical surface ($N > ?$). This may lead to some modification of usual theorems of electrostatic stability which claim that at the state of the equilibrium all charges in the conducting body are always located on the surface. The above example clearly illustrates that this is not necessarily so.

Spider pheromone 'packets'?

SIR — The scanning electron micrograph (SEM) of the pustuliform organ of the spider *Holcolaetis vidua* Lessert (Salticidae) reproduced in *Nature* of 7 March (p.17) shows spherical bodies on the surface. It is suggested that the spheres may be 'packets' of pheromone secreted by the pores, on the assumption that the organ is pheromone producing[1].

In reality the SEM shows that the spheres are not associated with the pores but occur on the pustuliform organs in proportion to the surface area occupied by the organs, about 25%. The implied low volatility of the spheres seems inconsistent with pheromonal function. The mean diameter of the spheres of 1.3 μm, size distribution, aggregation and general appearance are consistent with the spheres coating the chorion of spiders' eggs of all families, including salticids, that I have examined[2]. These spheres may be found on the surface of spiders newly emerged from egg cocoons[2] and the brood guarding behaviour of salticids may expose the adults to such contamination.

Scientific Correspondence is intended to provide a forum in which readers may raise points of a rather technical character which are not provoked by articles or letters previously published (where Matters Arising remains appropriate).

A multichannel seismic study of lithospheric flexure across the Hawaiian–Emperor seamount chain

A. B. Watts*, U. S. ten Brink*, P. Buhl & T. M. Brocher†

Lamont-Doherty Geological Observatory and * Department of Geological Sciences, Columbia University, Palisades, New York 10964, USA
† Woods Hole Oceanographic Institution, Woods Hole, Massachusetts 02543, USA

Existing models assume that the thickened crust beneath seamounts is the result of a surface volcanic load flexing an elastic plate. New results suggest that flexed oceanic crust beneath the Hawaiian–Emperor seamount chain is underlain by a 4-km thick deep crustal body. We intepret the body as a deep crustal sill complex associated with the tholeiitic stage of volcano building along the chain.

PLATE tectonics is based on the concept of a strong rigid lithosphere that overlies a weaker asthenosphere[1]. The principal evidence for the existence of a strong lithosphere on long time-scales ($>10^6$ yr) comes from studies of the way in which it responds to surface loads such as late glacial lakes[2], river deltas[3] and oceanic islands and seamounts[4]. One of the best-studied loads[5–11] is the Hawaiian–Emperor seamount chain in the Central Pacific Ocean. This volcanic load is suitable for study because: (1) it is located in the interior of a plate away from the complexities of plate boundaries; (2) it is one of the largest loads ($\sim 10^{18}$ kg) on the Earth's surface; (3) its tectonic setting is reasonably well known, enabling the relationship between load age and the thermo-mechanical properties of the oceanic lithosphere to be examined.

It has been known since the earliest gravity measurements[12] that the Hawaiian Islands are associated with large-amplitude free-air gravity anomalies that cannot be explained by local models of isostasy and require some form of regional compensation to account for them. Venning Meinesz[4] and Gunn[5] showed that gravity data over the islands are consistent with the flexure model of isostasy. According to their model, the Hawaiian Islands represent a load on the surface of the oceanic lithosphere which responds in a similar manner to an elastic plate overlying a weak fluid substratum. Walcott[7], Watts and Cochran[8], Watts[10] and Kunze[11] have shown, using this model, that the best fit to the gravity data is for an effective flexural rigidity of the oceanic plate in the range 5×10^{29}–5×10^{30} dyn cm, which corresponds to an effective elastic thickness, T_e, in the range 17.8–38.3 km.

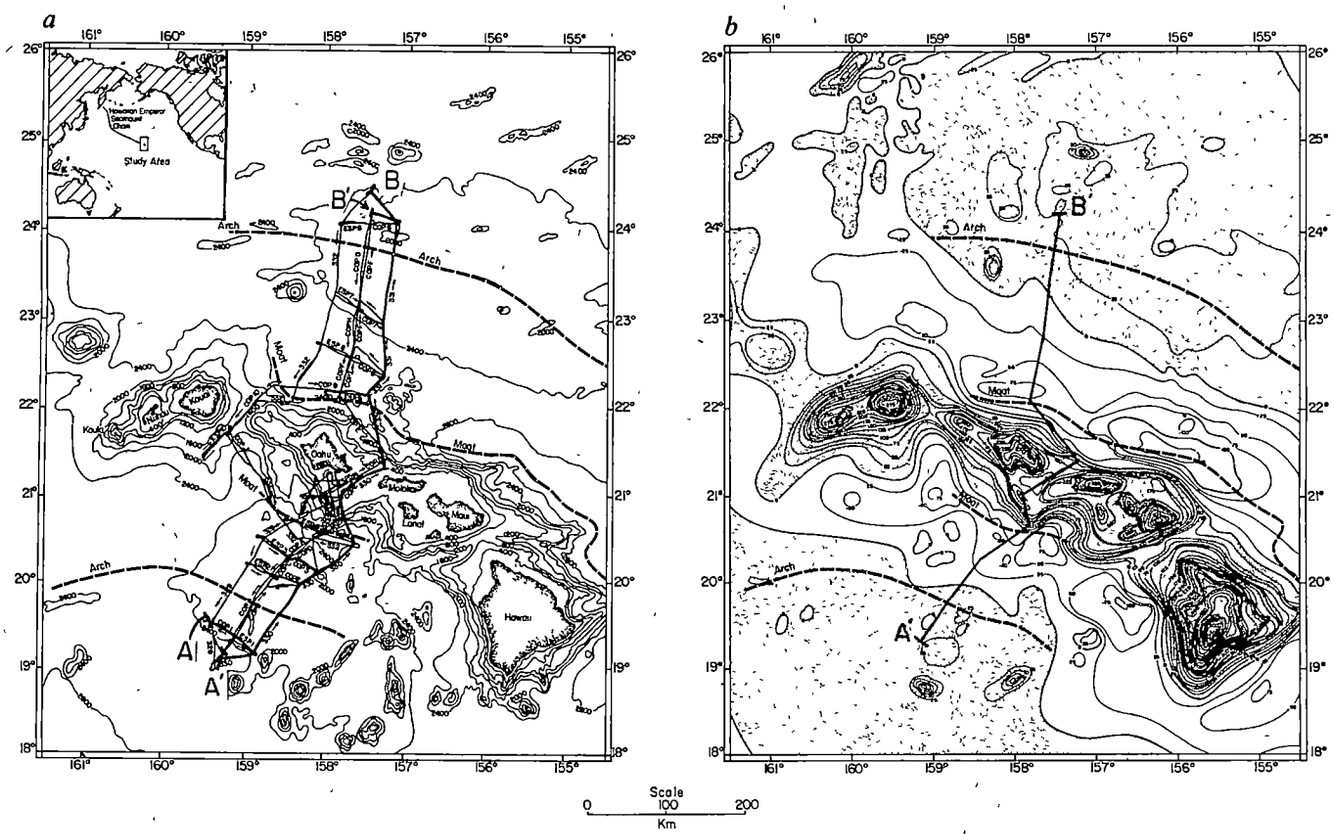

Fig. 1 Location map of the two-ship multichannel seismic experiment, *a*, Bathymetry; *b*, free-air gravity anomaly. In *a*, the contour interval is 400 fathoms (1 fathom = 1.8288 m) and is based on Chase *et al.*[34]. Fine track lines, location of individual CDP, COP and ESPs; heavy line, location of ESP 1/COP 1 (Fig. 3) and CDP 330/CDP 331 (Figs 1, 2, profile AB); A'B', end points of the free-air gravity anomaly and bathymetry profile connecting ESP mid-points In *b*, the contour interval is 25 mgal (1 mgal = 0.001 cm s^{-2}) and is based on Watts and Talwani[35]. Gravity anomalies >25 mgal are stippled. Thick dashed lines in *a* and *b* indicate the location of the Hawaiian arch and moat based on all available bathymetry profiles in the region.

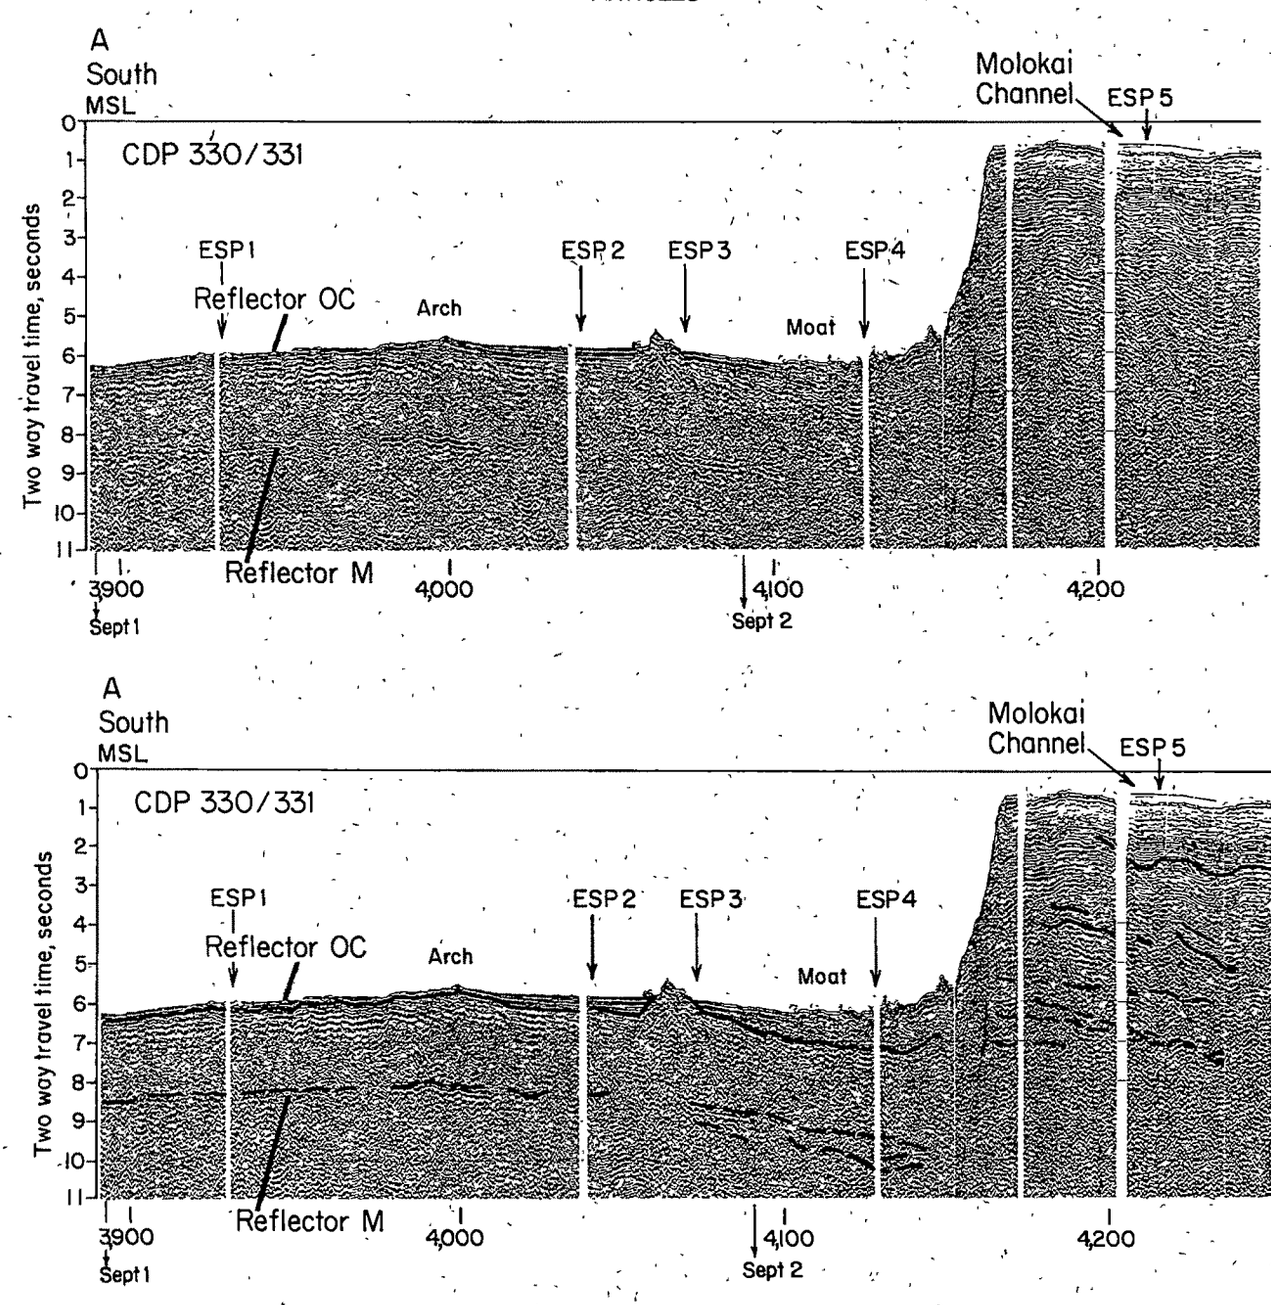

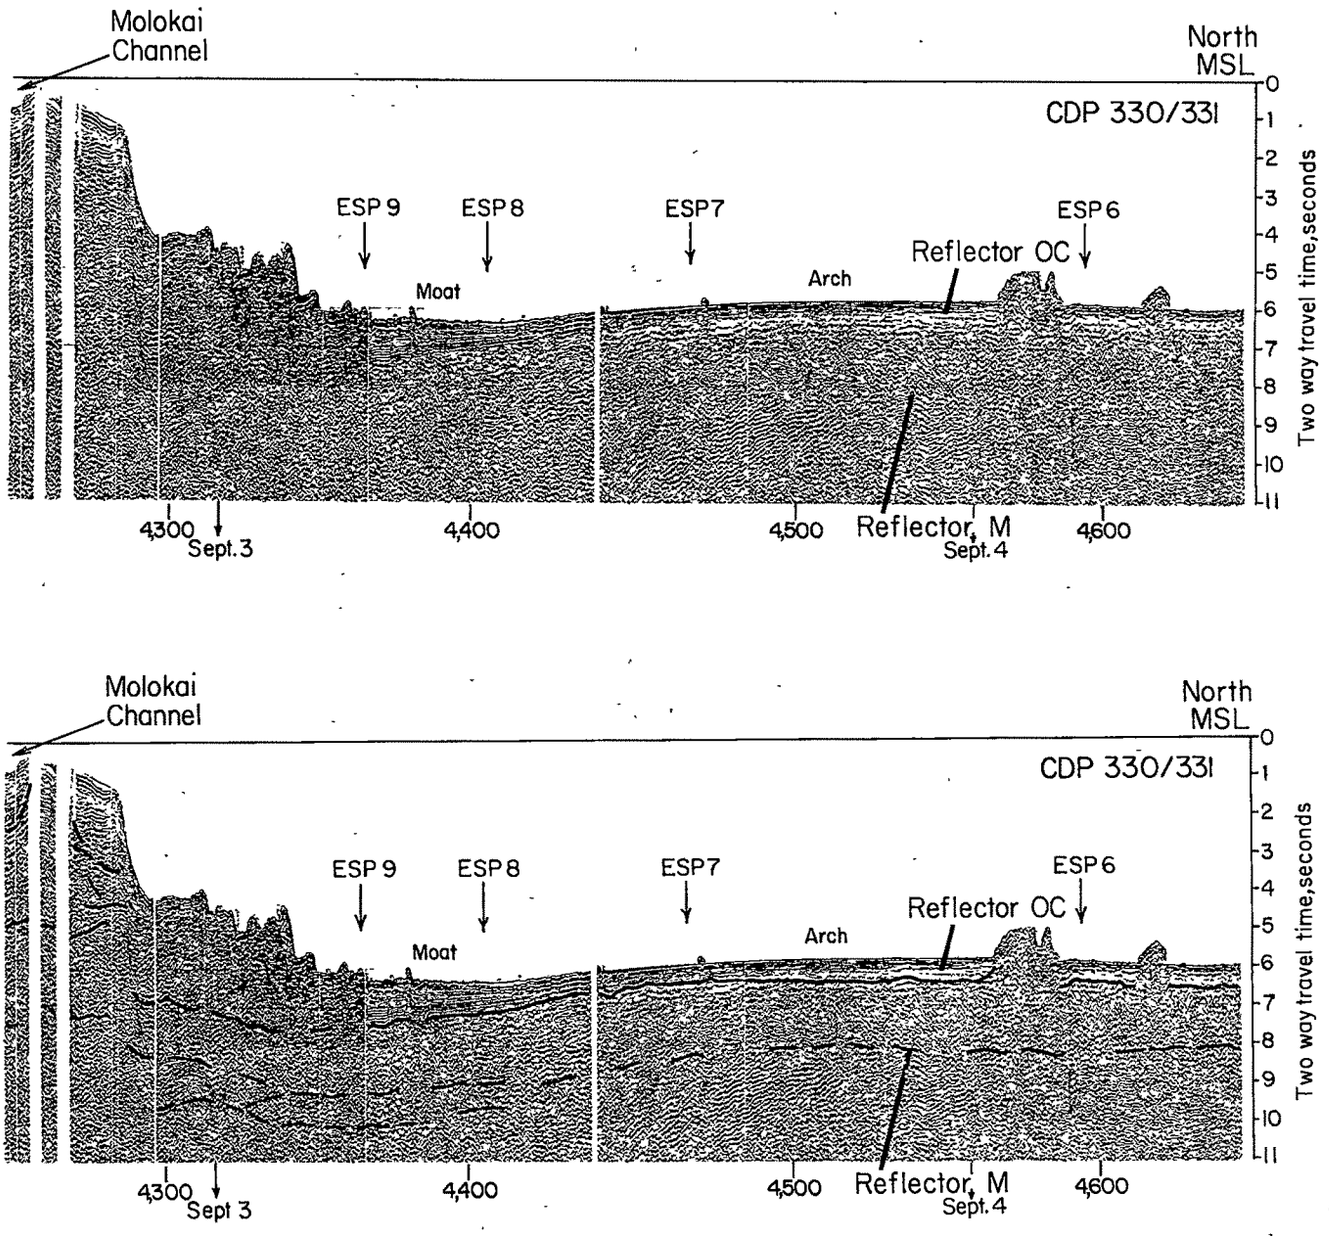

Fig. 2 (Above and opposite) CDP profiles 330 and 331 of the Hawaiian ridge and vicinity (Fig. 1*a*, profile AB). The 48-fold stacked section was acquired with a 3.6-km towed array. The black line on the upper section highlights prominent seismic reflectors. Reflector M at ~8.2 s below the arch is associated with the *M*-discontinuity and is continuous on a scale of ~50 km. Reflector OC is associated with the top of the oceanic crust. The number below the profiles is the accumulated distance in km along the ship track.

The actual value of T_e depends, however, on the type of flexural model that is assumed. For example, Walcott's[7] estimate is based on a model that assumes the plate is fractured beneath the islands, whereas Watts and Cochran[8], Watts[10] and Kunze[11] derive their estimates assuming a continuous plate. Both types of model are in isostatic equilibrium and produce similar shape gravity anomalies to observed profiles. Thus, gravity data have not been able to discriminate unequivocally between different flexure models.

An independent test of flexure is to use seismic data to constrain the predicted deformation of the plate. For example, Walcott[7] predicted that normal thickness oceanic crust is flexed by ~13 km beneath Oahu, whereas Watts[10] and Kunze[11] predicted only ~4 km. If the thickness of the oceanic crust in undeformed regions is 6 km, then these authors imply a depth to the *M*-discontinuity of 23.5 and 14.5 km for the fractured and continuous plate models, respectively.

During the early 1960s, a number of seismic refraction experiments were performed near the Hawaiian Islands, principally in support of Project Mohole (ref. 13). These experiments showed that in the region of the Hawaiian arch the mean thickness of the oceanic crust is ~6.3 km, increasing to ~13.0 km beneath the moat and ridge. Subsequently, Furomotu *et al.*[14] suggested that the crustal thickness is ~19–20 km beneath Oahu, thinning to ~17 km to the north-west beneath Kauai and ~10–14 km to the south-east beneath Hawaii. Unfortunately, these early seismic studies were hampered by poor navigation and drifting receivers and do not provide a suitable data set with which to constrain reliably the flexure model.

The purpose of this article is to summarize the results of a two-ship multichannel seismic experiment over the Hawaiian–Emperor seamount chain near the islands of Oahu and Molokai. A more detailed description of all the data obtained during the experiment will appear elsewhere (U. ten B. *et al.*, in prepar-

ation). The overall objective of the experiment was to define the detailed crustal and upper mantle velocity structure beneath a mid-plate volcanic island chain. We examine here the implications of the seismic experiment for the long-term ($>10^6$ yr) thermo-mechanical properties of the oceanic lithosphere and petrological models for the evolution of mid-plate oceanic volcanoes.

Seismic experiment

During August–September 1982, the Lamont–Doherty Geological Observatory and the Hawaii Institute of Geophysics carried out a two-ship seismic experiment near Oahu and Molokai in the Hawaiian Islands (Fig. 1). The experiment involved two vessels, the *Robert D. Conrad* and *Kana Keoki*, and used the single-ship multichannel seismic reflection profiling technique[15] to determine the configuration of individual crustal layers and the *M*-discontinuity and the two-ship technique[16] to determine the detailed velocity structure of the crust and upper mantle. The *Conrad* was equipped with a 3.6-km long seismic engineering multichannel streamer with 48 active channels and a large-volume (2,500 in^3) high-pressure sound source. *Kana Keoki* was equipped with a single-channel streamer, a large-volume (2,000 in^3) high-pressure sound source and 210 60-pound Tovex charges. Navigation for each ship was by satellite. During the two-ship portion of the experiment, the range between the two vessels was continuously measured by Miniranger and Raydist systems.

The seismic experiment consisted of normal incidence common depth point (CDP) data, constant offset profiles (COPs) and eleven expanding spread profiles (ESPs) obtained across a 600-km long, 100 km wide 'transect' of the Hawaiian ridge centred near Oahu (Fig. 1). The first part of the experiment included a continuous 250-km long COP between the Molokai channel and the Hawaiian arch south of the Hawaiian Islands (Fig. 1*a*). While shooting the COP, the two vessels maintained a constant distance apart of 3.6 km and *Conrad* and *Kana Keoki* alternately fired their airguns each minute. At the end of the COP, the vessels re-grouped for an ESP (Fig. 1*a*, ESP 1). During the ESP, the two vessels separated from each other at a speed of ~5 knots while *Kana Keoki* fired its large airguns each minute and *Conrad* received. At the end of the 65–90-km-long line, the two vessels turned and moved toward each other along the same profile. The ESP was then reshot with the *Kana Keoki* firing Tovex charges on a 10-min schedule. During the ESP re-shoot, *Conrad* fired its airguns each minute (with each 10-min shot missing) so that a CDP profile was obtained along the ESP. On

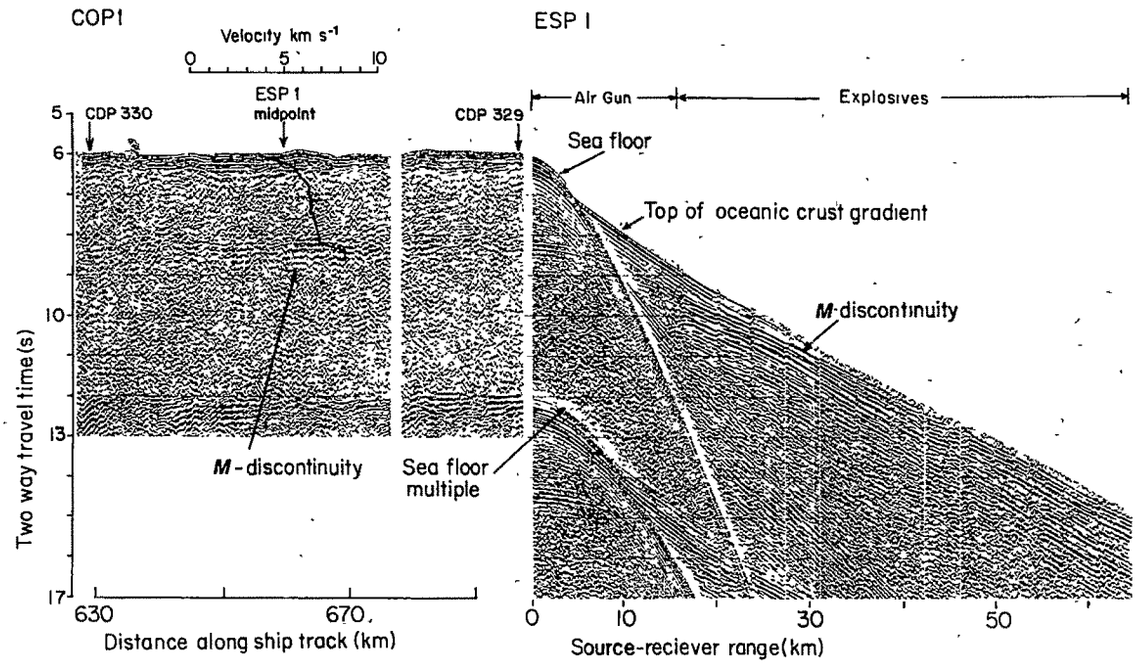

Fig. 3 ESP 1 and COP 1 of the Hawaiian arch, south of the Hawaiian ridge (Fig. 1*a*). The ESP data were obtained as the two ships separated at a constant speed from a common mid-point. At the end-point, the two ships steamed towards each other. During the 'outgoing' part of the experiment *Kana Keoki* fired its air guns and the *Conrad* received. During the 'ingoing' part *Kana Keoki* fired explosives. The ESP data shows a combination of the air gun and explosive record. The COP data were obtained by one ship (*Conrad*) firing its air guns and receiving. The black line on COP 1 represents the best-fitting velocity depth profile, obtained by a τ-p sum of the ESP X-T data.

completion of ESP 1, the vessels regrouped for a COP at a constant separation of 16 km to ESP 2. The COP/ESP sequence was then repeated until the transect had been completed south of the islands. The second part of the experiment was comprised of a similar sequence of COP/ESPs between the Molokai channel and the arch to the north. On completion of ESP 11, *Conrad* began a 1,200-km long CDP profile connecting the ESP end-points. During this portion of the experiment, *Conrad* fired its airguns on a 20-s schedule.

The data acquired during the seismic experiment were processed using techniques described by Stoffa *et al.*[17]. The ESPs were corrected for ship's navigation, the ranges between shot and receiver, shot times and clock synchronization. After demuxing the data, individual seismic traces were sorted and summed in bins of 50 and 100 m. We performed τ-p mapping of the stacked X-T data and carried out a τ-sum inversion (assuming horizontal homogeneous layers) on the τ-p data to yield a velocity-depth function at each ESP mid-point[17]. The solutions from τ-sum inversion were verified by forward modelling of first arrivals using velocity gradients and accounting for spherical losses. Also, the velocity-depth function was compared with the results of semblance analysis of CDP data near some ESP mid-points and the two-way travel time data on the CDP profile that crossed each ESP mid-point. The CDP data were processed using routine methods with some exceptions. Before stacking, velocity filtering was performed on parts of the profiles, each CDP gather was muted and the first and last traces eliminated. This additional processing removed multiples of the sea floor and sub-bottom reflectors and reduced the scattered energy associated with irregularities in each reflector. After stacking and predictive deconvolution, time-varying band pass filtering was applied to all the CDP data.

Results

We present here selected profiles of the ESP and CDP data gathered during the seismic experiment. Figure 2 shows CDP profiles 330 and 331 obtained by *Conrad* on a transect of the Hawaiian ridge between Oahu and Molokai (Fig. 1*a*). The figure shows a strong reflection (reflector M) from the M-discontinuity at ~8.2 s two-way travel time beneath the Hawaiian arch south of the islands and at ~8.0 s north of the islands. In general, the reflector is stronger south of the islands than to the north. The travel time difference between the sea floor and the reflector is ~2.0 s north of the islands and 2.4 s to the south. We interpret these differences as indicating that the oceanic crust is thicker south of the islands than to the north. The travel-time difference between the sea floor and reflector M increases from the arch to the moat indicating an increase in the thickness of the crust beneath the moat. At ~4,070 km (Fig. 2), there is evidence that reflector M 'splits' at a two-way travel time of ~9.1 s. We interpret this split in the M-discontinuity as the result of a deep crustal layer underlying the oceanic crust beneath the moat and ridge. The top of the oceanic crust is characterized by a generally weak reflector (OC) with rough topography underlain by low frequency 'multiples'. Other strong reflectors are associated with the poor-to-well stratified material of the moat infill.

Figure 3 shows ESP 1 (Fig. 1*a*) obtained by *Conrad* and *Kana Keoki* near the Hawaiian arch south of the islands. The right-hand side of the figure shows a line of refracted arrivals which are nearly tangential to the top of oceanic crust and M-discontinuity reflectors. There are departures, however, from straight refraction lines. For example, at ranges of 5–25 km there is a convex downward curvature of the primary refracted arrivals, suggesting a continuous increase in velocity with depth, while at ~27.5 km there is a gap in primary arrivals, suggesting an abrupt decrease in the velocity gradient with depth. The CDP profile (Fig. 3) shows a strong reflector associated with the M-discontinuity between 8.15 and 8.45 s. The solid line at the ESP 1 mid-point on the CDP is the velocity-depth function obtained by τ-p mapping of the X-T data and τ-sum inversion. The velocity-depth function shows a progressive increase from 2.5 to 8.1 km s^{-1}. Abrupt changes in the velocity gradient are associated with the top of the oceanic crust and the M-discontinuity.

The principal results of the CDP data and ESPs 1-9 are summarized in Fig. 4. The velocity-depth data at each ESP mid-point and the depth to prominent reflectors on CDP 330/331 have been projected onto bathymetry profile A'B' (Fig. 1*a*). Figure 4 shows that the total crustal thickness increases from ~6.5 to 6.8 km beneath the Hawaiian arch to ~10.5–12.0 km

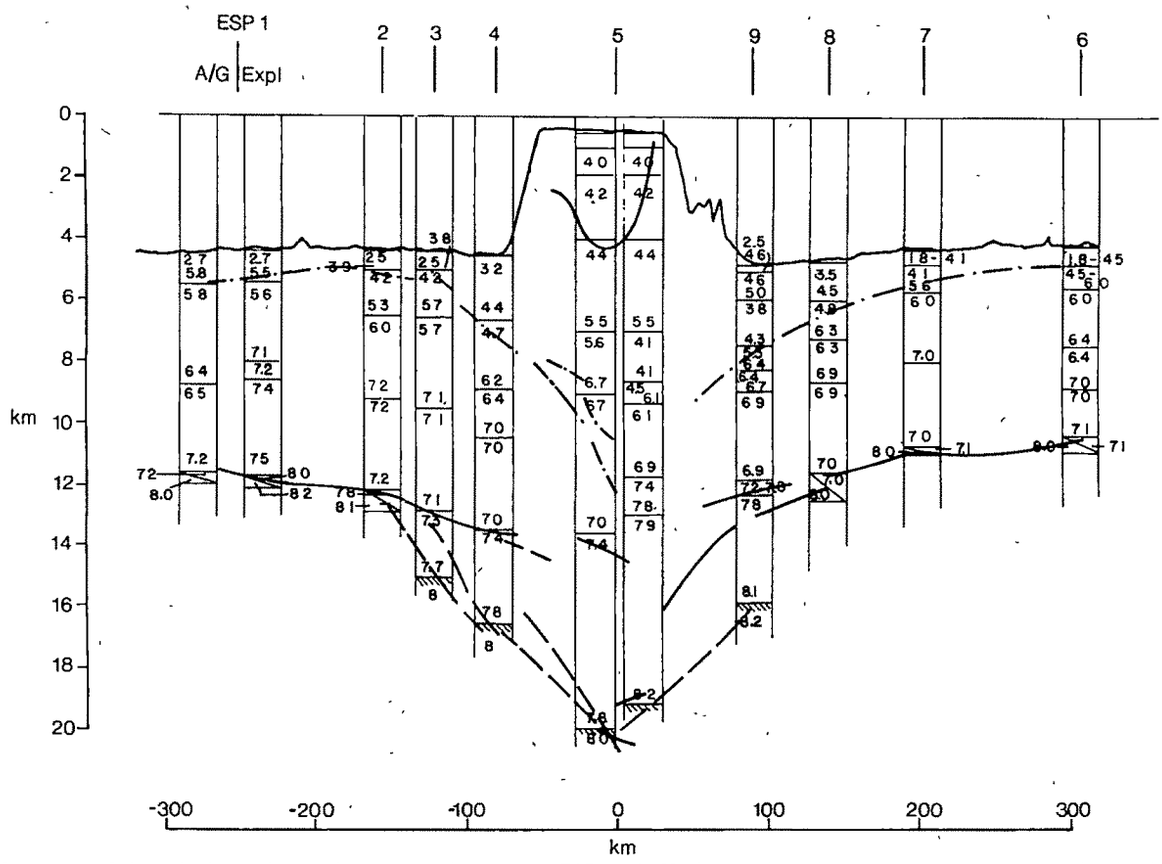

Fig. 4 Summary of the velocity and crustal structure obtained on ESPs 1-9. Horizontal lines in each column represents the depth to a prominent change in velocity with depth. The numbers refer to the velocity (km s^{-1}) immediately above and below the velocity change. The dashed-dot, continuous, and dashed lines represent prominent reflectors in Fig. 2 which have been converted to depth using the ESP velocity data results. These three reflectors are interpreted as corresponding to the top of the oceanic crust, the base of the pre-flexed oceanic crust and the *M*-discontinuity respectively. The ESP data have been plotted at the intersection of each ESP with profile A'B'. Note that two possible solutions are shown for ESPI and ESP5.

beneath the moat, and 18.0-19.0 km beneath the ridge. In the region of the arch, the crustal layer below reflector OC has a velocity which grades from 4.2 to 5.6 km s^{-1} (ESP 1, 2, 6, 7) to ~8.0-8.2 km^{-1}. Below reflector OC in the moat there is a sudden increase in velocity from 7.0 to 7.4 km s^{-1} at depths of 6.5 km below the sea floor (ESP 4) and from 6.9 to 7.2 km s^{-1} at 7.0 km to the north (ESP 9). At ESP 5 on the ridge, reflector OC cannot be as easily identified. Furthermore, the $X-T$ data cannot be interpreted in terms of a single velocity-depth profile. Figure 4 shows two possible solutions for ESP 5, both showing a similar upper crustal structure with velocities increasing from 4.0 to 5.5 km s^{-1}. At greater depths, however, the two solutions differ. The solution, which does not include a low-velocity zone (LVZ) in the upper crust, is characterized by a sudden increase in velocity from 7.0 to 7.4 km s^{-1} at depths of ~13.0 km below the sea floor, whereas the model with a LVZ shows a sudden increase from 6.9 to 7.4 km s^{-1} at depths of ~11.3 km. Above reflector OC, velocities are generally in the range 2.3-4.0 s^{-1}. At ESP 9 in the moat region, there is evidence from arrivals on $X-T$, τ-p and from amplitude data for a LVZ above reflector OC. We interpret this LVZ as the result of a high-velocity lava flow capping low-velocity material of the moat infill.

To constrain better the crustal model, we computed the gravity and geoid effect of the seismic structure and compared it with the observed free-air gravity anomaly profile obtained on *Conrad* and *Kana Keoki* and the geoid anomaly derived from SEASAT radar altimeter data. Because of uncertainties in the seismic interpretation at ESP 5 (Fig. 4), two models for the deep crustal structure of the ridge were considered: one in which the oceanic crust is thinned beneath the ridge (Fig. 5, model A) and one in which the crust is of normal thickness (Fig. 5, model B). Model A is consistent with the solution without a LVZ in the upper crust, whereas model B agrees better with the solution with a LVZ. For the purposes of the gravity and geoid calculation, the velocity-depth data near the arch and moat were generalized to an upper 4.2-6.0-km s^{-1} layer, a middle 6.0-7.1-km s^{-1} layer and a lower 7.4-7.8-km s^{-1} layer. Densities of 2.6, 3.0 and 3.15 g cm^{-3}, respectively, were assigned to these layers using the velocity-density relationships of Christensen and Salisbury[18]. We assigned a density of 2.3 g cm^{-3} for the material filling the moat, a density similar to the average density of vesicular Hawaiian flows[19] and in the range of values normally chosen for sediments. At ESP 5, the volcanic 'core' of the ridge is associated with velocities of 4.0-6.7 km s^{-1}. A density of 2.5-2.7 g cm^{-3} was assigned for the core of the ridge, similar to values normally considered for volcanic flows[19].

Figure 5 shows that there is a good overall agreement between the observed and the calculated gravity and geoid anomalies based on the seismic structure. Gravity and geoid data agree with the suggested thickening of the crust from ~6.5 km beneath the arch to 12.0 km beneath the moat and 18.0-19.0 km beneath the ridge. Furthermore, the data are consistent with the existence of a deep crustal layer underlying oceanic crust beneath the ridge and a portion of the flanking moat. The data cannot, however, distinguish whether the oceanic crust is thinned beneath the ridge or whether it has a similar thickness as beneath the moat and arch. Figure 5 shows that if oceanic crust is normal thickness beneath the ridge a high density body is required beneath it to compensate for the additional low density associated with the increase in thickness of the oceanic crust. The origin of the body is not clear, but gravity modelling suggests that it represents a deep seated extension of the dense volcanic pipe associated with the Koolau caldera on Oahu[20].

Implications

The seismically determined crustal structure of the Hawaiian ridge has implications for both the thermo-mechanical

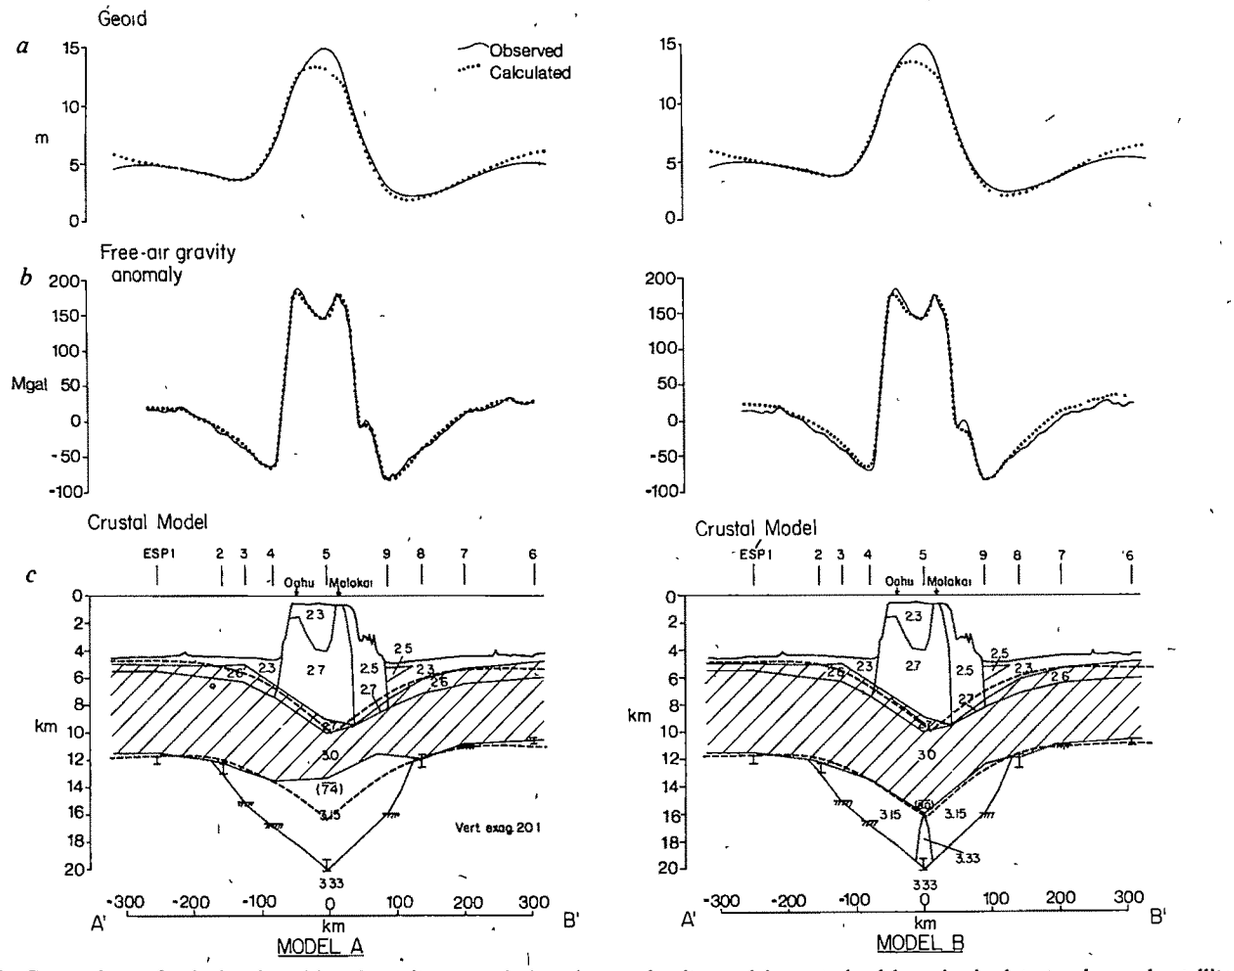

Fig. 5 Comparison of calculated geoid and gravity anomaly based on a density model constrained by seismic data to observed satellite derived geoid and surface-ship free-air gravity anomaly data. *a*, Geoid anomaly obtained by subtracting the geoid derived from a descending track of SEASAT from the GEM 10 Earth model complete to degree and order 12. *b*, Free-air gravity anomaly profile derived from data obtained by *Conrad* and *Kana Keoki* during COP A/COP B and COP E/COP F. *c*, Density model based on velocity-depth data in ESPs 1-9 and the velocity-density relationships of Christensen and Salisbury[19]. The configuration of the models (see text) have been adjusted so as to best-fit the gravity and geoid data and still explain the seismic data. Model A, thinned oceanic crust; model B, normal thickness oceanic crust. Heavy dashed lines are calculated curves based on a flexure model of isostasy with $T_e = 25$ km.

properties of oceanic lithosphere and petrological models for the evolution of mid-plate seamount chains.

The configuration of the oceanic crust near Oahu and Molokai is compared with predictions based on a flexure model of isostasy described in Fig. 5. In the model, it is assumed that the Hawaiian ridge and its associated infill material represent a two-dimensional load on the surface of an elastic plate overlying a weak fluid substratum. Thus, we assume that the only loads that act on the plate are surface loads and that buried loads[21] do not contribute to the flexure. Figure 5 shows that there is a reasonable agreement between the configuration of the upper surface of the oceanic crust and the calculated flexure profile for $T_e = 25$ km. There is also good agreement between the calculated profile and the configuration of the base of the oceanic crust for the model in which the oceanic crust is uniform in thickness beneath the ridge. Figure 5 shows, however, that the agreement is poor for the model in which the oceanic crust thins beneath the ridge. These results, therefore, suggest that beneath the ridge, flexed normal thickness oceanic crust is either underlain by a high density body (model B) or has been altered by densification in its lowest part (model A).

The flexure profile in Fig. 5 is based on a single value of T_e and a fractured plate model. Other values of T_e would be required if different types of flexure model are used. For example, if a continuous rather than a fractured plate had been used, then a lower value of T_e (~ 20 km) would be required. We prefer the fractured plate model (and hence the higher T_e value) because it best explains the shape of the top of the oceanic crust below the moat and the edge of the load. We caution against a too literal interpretation of the T_e value in Fig. 5, however, because it may be possible to construct other models (for example, a model in which T_e decreases gradually from beneath the arch to the ridge) that could explain the seismic, gravity and geoid data (Fig, 5) equally well. A value of $T_e = 25$ km can, therefore, be regarded as a 'best fit' to the regional crustal structure of the ridge and hence, a measure of the average response of oceanic lithosphere to volcanic island loading along the Hawaiian-Emperor seamount chain.

Oceanic flexure studies[10] have shown that T_e is a strong function of the age of the lithosphere at the time of loading. Thus, volcanic loads formed on young lithosphere are associated with small values of T_e, whereas loads formed on old lithosphere are associated with large values. There is a good agreement between T_e and the depth to the 450 °C oceanic isotherm based on the cooling plate model. Bodine *et al.*[22] have considered these results in terms of the rheology of oceanic lithosphere based on data from experimental rock mechanics and shown that

$$T_e \simeq 4.3t^{1/2}, \text{ 'dry' olivine rheology} \quad (1)$$

$$T_e \simeq 3.3t^{1/2}, \text{ 'wet' olivine rheology} \quad (2)$$

where t is age of the oceanic lithosphere (Myr) at the time of load emplacement. Using $t = 80$ Myr in equations (1) and (2) gives a predicted T_e of 30–40 km, which is somewhat higher than the value of T_e deduced here.

Although T_e at a volcanic load is a function for the thermal age of the underlying oceanic lithosphere[10], it may not represent the actual temperature structure of the lithosphere because of perturbing effects associated with magmatic processes and/or subsequent thermal events. Crough[23], for example, suggested that the Hawaiian swell is the result of thermal uplift following reheating of oceanic lithosphere by the Hawaiian hotspot. He estimated from bathymetric data that the 80 Myr lithosphere near Hawaii has been reheated to a thermal age of ~30 Myr. Substituting this value in equations (1) and (2) gives a predicted T_e of 18–23 km, which is similar to T_e estimated here. However, Sandwell[24] computed the response of a moving plate over heat sources with different shapes and has shown that the peak in the temperature distribution may be displaced ≤20 Myr downstream of the source. The age of the volcanic load near Oahu and Molokai is only ~2–3 Myr, so that the T_e estimated here cannot be used to constrain the reheating hypothesis. Thus, the strongest evidence for the swell remains the exponential form of its subsidence.

Although the extent of lithospheric reheating is uncertain, it is clear that a flexure model of isostasy with $T_e = 25$ km can explain the overall configuration of the oceanic crust near Oahu and Molokai. The model cannot, however, account for the 7.4–7.8 km s^{-1} velocity layer which seismic, gravity and geoid data suggest underlies flexed oceanic crust beneath the islands. This deep crustal layer is ~4 km thick, 200 km wide and generally symmetric below the centre of the ridge.

It is known from petrological studies that the Hawaiian volcanoes erupt lavas of different and distinct chemical compositions during their evolution. According to McDonald[25], the main stage of volcano building consists of large amounts of tholeiitic lavas which erupt rapidly (≤ 1 Myr; ref. 26). Following the main stage, the volcano usually erupts small amounts of alkali basalts. Finally, after a few Myr of quiescence, minor amounts of nephelinic lavas may erupt from satellite vents. The exact nature of the source region of the tholeiites and alkali basalts is not known[27,28] but seismicity studies near Hawaii[29] suggest that magma transfer associated with the tholeiitic stage of volcanism extends to depths of at least 50–60 km. The nephelinic lavas are considered to be more primitive and to have originated from an even deeper source.

Seismic studies provide constraints on the velocity and density structure of the crust and upper mantle beneath a volcano and hence are of importance in developing petrological models. For example, seismic data[30] suggest that Mount Etna is underlain by a deep seated magma chamber.

From a consideration of all the seismic data obtained during the experiment, we believe that the most probable interpretation of the deep crustal body underlying flexed oceanic crust beneath Oahu and Molokai is that it represents a deep crustal sill complex. In particular, the body represents 'frozen' intrusions of tholeiitic composition into upper mantle rocks that were trapped in their ascent from a deeper source during the late phase of the tholeiitic stage or during the following period of quiescence. Such a model of a crust–mantle 'mix' agrees with seismic data showing that the deep crustal layer is intermediate in velocity between that of lower crust (gabbro) and upper mantle (peridotite) rocks. It is also in agreement with evidence[31,32] which shows an absence of a deep crustal body below Kilauea and Mauna Loa on Hawaii. These volcanoes seem to be in the early phase of the tholeiitic stage and, therefore, would not be expected to be underlain by such a sill complex.

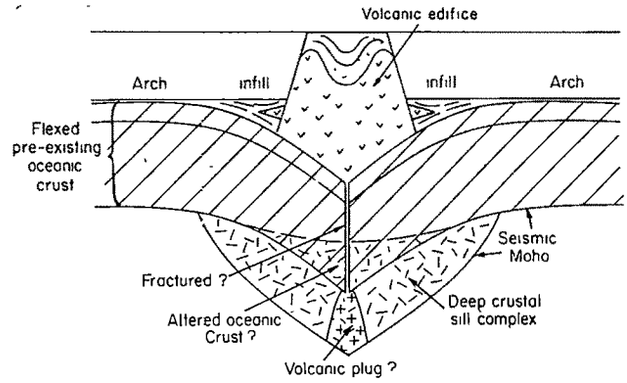

Fig. 6 Schematic model of the crustal structure of the Hawaiian ridge and vicinity based on the seismic, gravity and geoid data discussed here. The model has been generalized from models A and B in Fig. 5.

Figure 6 shows a schematic model for the deep crustal layer beneath Oahu and Molokai that explains the geophysical data and is consistent with current petrological knowledge. In proposing this model, we have eliminated (on density arguments) the possibilities that the deep layer represents either a magma chamber of basic picritic magmas which become ponded at or near the crust/mantle following their ascent through the mantle[33], or dunites and plagioclase-bearing pyroxenites that formed as early cumulates in a fractionating tholeiitic magma chamber[28].

The deep structure of oceanic islands and seamounts, however, is still too poorly known and other explanations may be proposed as more data become available. The seismic experiment described here was the first of its kind to be carried out over a mid-plate seamount chain. We believe that multichannel seismic studies of other seamounts offer particular promise of better understanding the origin of mid-plate volcanism in the future.

We thank J. Mutter, J. Glasser, C. Mountain, E. Vera, D. Lindwall, C. Zehnder and the officers and crew of RVs *Conrad* and *Kana Keoki* for their help at sea and J. Mutter and J. Weissel for critical reviews. This work has been supported by NSF grants OCE 81-11704 (L-DGO) and OCE 81-17210 (WHOI). Lamont-Doherty contribution 3797.

Novel type of crust produced during continental rifting

A. Nicolas

Laboratoire de Tectonophysique, 2 rue de la Houssinière, 44072 Nantes Cedex, France

A normal oceanic crust cannot be generated after continental crust splitting of rifts filled by a thick pile of young sediments. The magma released by the rising mantle is trapped mainly in these sediments as basalts sills and plugs. The sediments are themselves metamorphosed by the heat flux from the underlying mantle. A metasedimentary crust is formed in direct contact with an abnormal mantle ($V_p \simeq 7.5$ km s^{-1}) produced by partial serpentinization.

THE transition from continental to oceanic crust in a rift may occur in a number of different ways. One model involves the stretching of the continental crust to a thickness comparable with that of the oceanic crust, followed by a transition to this new oceanic crust. This model has been documented by the study of the Atlantic Ocean passive margins[1,2]. Another model predicts a brittle behaviour of the continental crust which would be progressively invaded by mafic dykes, its extension being that of the accumulated thickness of the dykes, and would finally yield without stretching along the mechanically weakened zone of dyke intrusion, passing more abruptly to oceanic crust[3,4]. Coleman[5] describes an intermediate behaviour of dykes and igneous bodies with crustal extension and multiple intrusions which seem to produce locally a complete disruption of the continental crust on the Arabian side of the Red Sea.

In these models, the nature of oceanic crust is little questioned, despite geophysical records which are not always those of typical oceanic crust. It is also implicitly accepted that an oceanic crust can be formed whatever the sedimentary filling of the rift. Is it possible to form a normal oceanic crust, just after the splitting of continental crust, in a trough filled with kilometres of wet sediments? Saunders *et al.*[6] have shown that in the Guaymas Basin of the Gulf of California, where the sedimentation rate can exceed 1,200 m Myr^{-1}, the oceanic layers 1 and 2 are partially intercalated, the young sediments being intruded and metamorphosed by many doleritic and gabbroic sills. Here, I show that in such environments the situation may be even more radical with a total absence of layer 3 and a modified upper mantle lying directly below metamorphosed sediments invaded by basaltic intrusions. Thus, I define a new type of crust, the metasedimentary crust, transitional between the continental and oceanic crusts.

I will discuss geophysical evidence from two well-known rifting environments (Salton Trough at the north end of the Gulf of California, and the southern Red Sea) and from the western Pyrénées where, starting from a similar situation during the Cretaceous[7], it is now possible to observe the deep parts of the crust and the upper mantle peridotites, from mountain building data. The study of these peridotites supports my interpretation. Finally, I suggest an answer to the problem of the crust or mantle nature of the 7.2–7.5 km s^{-1} layers often found in non-typical oceanic lithosphere at depths between crust and mantle.

Salton Trough

The Imperial Valley–Salton Sea subsiding rift corresponds to the transition of the oceanic crust of the Gulf of California to the continental crust of southern California. This rift is opening in a system of large dextral strike-slip faults limited to the north-east by the San Andreas fault. It is rapidly subsiding with the Pleistocene Colorado River delta formations now at depths of 3.7 km below the Salton Sea and 4.8 km below the Mexican border[8].

In the trough below sedimentary layers, Fuis *et al.*[8] define a basement ascribed to deeper sediments metamorphosed in the greenschist facies (Fig. 1). This is based on the geophysical properties of this zone and on thermal measurements in deep wells, the extrapolation of which fix the top of the basement at 300 °C for a depth of 6 km. Basaltic intrusions occur in this basement. At a depth of ~12 km, one passes into the sub-basement through a 1-km thick transition zone. This sub-basement is ascribed to a mafic layer (gabbros and/or amphibolites) representing the oceanic crust on behalf of a P-wave velocity $V_p = 7.2$ km s^{-1} and a modelled density of 3.1 (Fig. 1). The 7.2 km s^{-1} velocity, however, is a lower limit; velocities of 7.5–8.0 km s^{-1} have also been reported. A recalculation of the same data gives an average velocity of 7.5 km s^{-1}. Here I reinterpret the sub-basement as anomalous mantle rather than mafic crust.

Fitting a P-wave velocity of 7.5 km s^{-1} and a density of 3.1 with an oceanic lithosphere formation can be done by a comparison with experimental data on ophiolite specimens or from a direct comparison with *in situ* geophysical data in the oceanic lithosphere. Ascribing to the upper sub-basement pressure–temperature (P–T) conditions of ~4–5 kbar and 400–600 °C, the appropriate comparison should be done with a young crust rather than with a nascent or a mature oceanic lithosphere.

Measurements on gabbros and metagabbros at 4-kbar confining pressure and room temperature give a wide range of velocities with mean values respectively of 7.14 km s^{-1} and 6.92 km s^{-1} for a few west American ophiolites[9]; data from Oman[10] or from the Bay of Islands[11,12] do not differ significantly. Correction for an assumed temperature of 500 °C would lower these values by ~5% (ref. 13). Density measurements on gabbros and metagabbros at normal P–T conditions on the same specimens as above give 2.95 and 2.92, respectively. Data from the

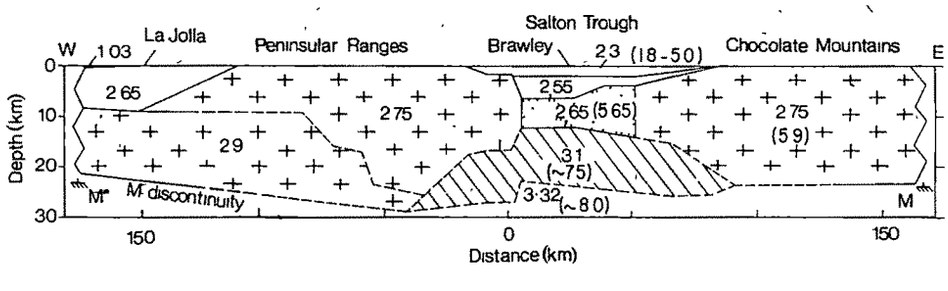

Fig. 1 Cross-sections through the Salton Trough integrating seismic (velocities in bracketed numbers) and gravimetry (plain numbers) data. Dots, metasedimentary basement; crosses, continental basements; oblique hatches, sub-basement (after Fuis *et al.*[8]). The 7.5 km s^{-1} velocity adopted for the sub-basement is derived from ref. 8 and from recalculated velocities using their data.

Table 1 P-wave velocities in layer 3 and upper mantle of young lithospheres

	Reykjanes[38]	Iceland[39]	Galapagos[40]	EPR* 10° S[40]	EPR Siqueiros[41]	EPR 12° N[42,43]	EPR 14° N[44]	Gulf of Aden[45]	Kenya[46]
V_p in layer 3 km s^{-1}	6.5	6.5	6.5	~6.8	7.0	6.8–7.2	6.8–7.0	6.3	
V_p in upper mantle km s^{-1}	7.3–7.4	7.2	7.5	7.5	7.8	8.0	7.75	7.2	7.3–7.5

* EPR, East Pacific Rise.

Table 2 Comparisons between Salton Trough P-wave velocities and other estimates

	Salton Trough sub-basement 4 kbar/500 °C	Gabbro metagabbro 4 kbar/500 °C	Layer 3 young crust	14% Serpentinized peridotite 4 kbar/500 °C	Upper mantle young lithosphere
V_P km s^{-1}	~7.5	6.57–6.78	6.3–7.2 (6.7)	7.34	7.4–8.0 (7.5)
D g cm^{-3}	3.1	2.85–2.88 ≤3.08		3.12	

Figures in parentheses represent average values from Table 1.

Bay of Islands and Oman show comparable densities with lower gabbros reaching densities of 3.15. Recalculating these densities for $P = 4$ kbar and T = 500 °C with compressibility and thermal expansion coefficients of 1×10^{-6} bar^{-1} and 24×10^{-6} deg^{-1}, respectively, would lower these densities by ~0.07, bringing them in the range of 2.88 and 2.85, with the maximum density lowered to 3.08.

An ultrasonic compressional wave measured along the main structural directions on a peridotite with 14% serpentine at 4 kbar gives an averaged velocity of 7.63 km s^{-1} (ref. 14). The results are similar using Christensen's[15] analytical data: 7.6 km s^{-1} for a peridotite (2/3 olivine, 1/3 enstatite) with 15% serpentine. Using the temperature derivative calculated for a comparable peridotite[16], one finds for $P = 4$ kbar and $T =$ 500 °C, a velocity of 7.35 km s^{-1}. The density measured on the same specimen was 3.2, which after the pressure and temperature correction, becomes 3.12.

P-wave velocity data for young oceanic lithosphere and rifts have been compiled in Table 1. When possible, the data for age zero have been avoided. Velocities in the upper mantle are commonly anisotropic, in which case they have been averaged.

Table 1 indicates that anomalous mantle velocities ~7.5 km s^{-1} are common below young oceanic crust where they are ascribed to the strong temperature effect on this velocity. With ageing, these velocities would increase to the more common 8.2 km s^{-1} value[17]. Table 2 shows that a peridotite with 10–20% serpentine fits equally well the data for Salton Trough.

Considering the fact that in the Salton Trough a source of water is found in the overlying sediments undergoing metamorphic reactions, I suggest that the upper part of the sub-basement and the transition zone are composed of partly serpentinized peridotites. The serpentinization decreases downward partly because it is difficult for the water to penetrate deep into the peridotites, but principally because the upper temperature limit for serpentinization (500 °C) is met at shallow depth in the sub-basement. At higher temperatures, tremolite–chlorite and talc can be present, contributing to the thermal effect and maintaining low velocities.

Southern Red Sea

Although the geophysical data are older and less tractable, a comparable situation with the Salton Trough seems to exist in the southern Red Sea, south of the 17° parallel. The magnetic anomaly pattern suggests the existence of oceanic crust in the central and southern Red Sea[18,19]. This is confirmed for the central Red Sea by seismic refraction data[20]. There, material with a mean seismic velocity of 4.3 km s^{-1} and thought to be evaporites, overlies a layer of mean velocity 6.6 km s^{-1}, thought to be oceanic crust.

In the southern Red Sea, seismic refraction and gravimetry profiles[21] and structural reconstitutions[22] in the 50–100-km-wide central trough define sedimentary layers 2–5 km in thickness with velocities from 2.75 to 4.48 km s^{-1}, overlying directly a 7.16–7.31 km s^{-1} domain. These overlying layers are evaporite sediments[22] associated with mafic formations. Seismic reflection profiles[23] suggest the occurrence of volcanic strata and plugs in the sediments. There is a general consensus that the underlying domain is mantle[22–24] whose anomalously low velocities are related to the locally high thermal gradient. Similarly, low mantle velocities have been reported from the adjacent areas[24] (Afar, Danakilh, Jibuti, Gulfs of Tajura and of Aden).

The abundance of mafic intrusions in the southern Red Sea and along its margins can account for the magnetic anomalies mentioned above and do not necessarily imply the presence of an oceanic crust that is not supported by the available geophysical record. Equating the 7.2 km s^{-1} basement with anomalous mantle, we conclude that this mantle is directly overlain by a sedimentary cover with mafic sills or flows and plugs. New seismic refraction profiles would be necessary to test this interpretation.

Western Pyrénées

During the Pyrenean orogeny, small and deep sedimentary basins, possibly analogous to those described above[7] have been squeezed, making it possible to obtain some information on the nature of their substratum.

These sedimentary troughs were filled by flysch during their opening. Thus, 3–6-km-thick flysch was accumulated rapidly in the western Pyrénées where the troughs are best developed. After a period of Triassic continental rifting followed by a relative quiescence, the rifting was reactivated during the Upper Jurassic–Lower Cretaceous[25], with the formation of the troughs under consideration. The precise mechanism for their opening is still unknown. The troughs may open by a pull-apart mechanism related to the essentially sinistral motion of the Iberia block with respect to Europe[7], or there may be a period of extensional tectonics within Iberia, followed by the strike-slip motion and the compression responsible for the mountain building event[26]. The first model seems to better explain the larger opening observed in the western Pyrénées. The content of the troughs has been metamorphosed. Temperatures as high as 600 °C were attained locally during the Albian–Cenomanian phase of the rifting[27]. During the subsequent compressional phase, they were still high enough to produce metamorphic effects.

In the eastern Pyrénées, the continental crust was probably only attenuated during stretching[28]. The mainly calcareous sediments from the basins contain small mafic and lherzolitic bodies, the latter associated with granulite slivers derived from lower

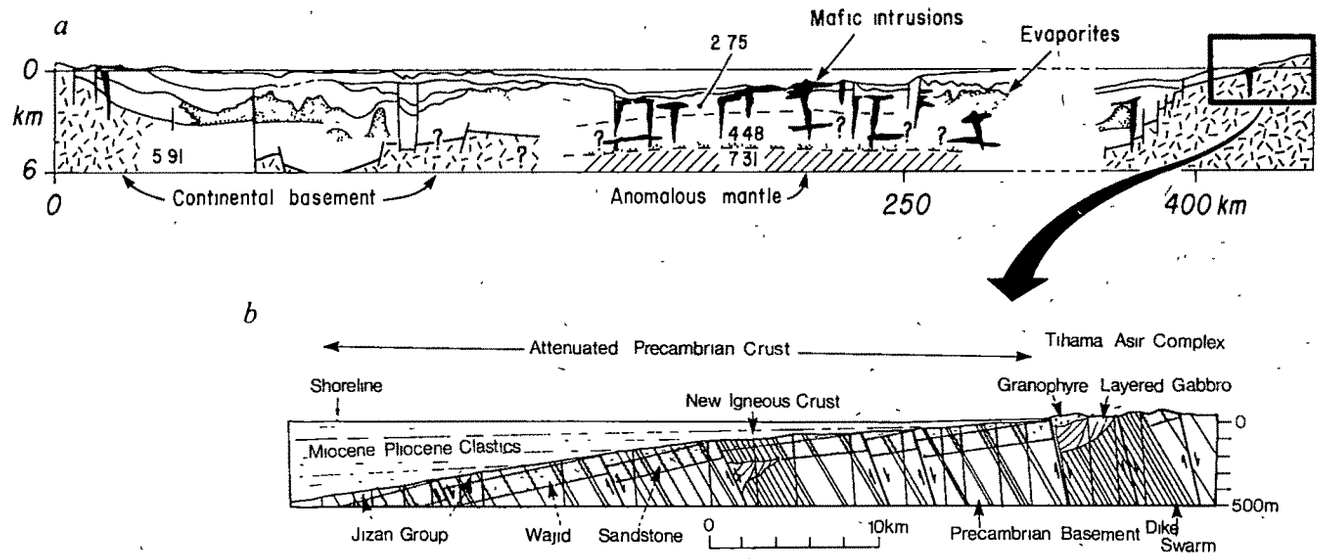

Fig. 2 Cross-section through *a*, southern Red Sea (near 17° parallel) and *b*, Saudi Arabia passive margin, illustrating the contrast in mafic magmatic activity: in the Red Sea trough, mafic sills, plugs and flows and along the passive margin, local creation of oceanic crust (ophiolites). *a*, Modified from Mulder *et al.*[23] by adding main seismic refraction results[21] and presumed deeper mafic intrusions in the 4.48 km s^{-1} layer; *b*, reproduced from Coleman[5].

continental crust and modified at depth by the thermal effects of the lherzolites[29]. These numerous lherzolite bodies are remarkably fresh with a plastic deformation indicative of large strain in the $T \approx 1{,}000$ °C range, but locally down to 650–700 °C (ref. 30), which we ascribe to their ascent.

In the western Pyrénées, the continental crust was probably disrupted[26–28]. This is suggested by the nature of the troughs and the large gravity anomaly. The small peridotite massifs upthrust during the orogeny are more harzburgitic (F. Boudier and F. Cordellier, personal communication). They are also largely serpentinized (lizardite), essentially at low temperatures and in static conditions, but with relicts of a high temperatures earlier stage in the greenschist facies (antigorite–tremolite–chlorite). The mafic intrusions are mainly ophites which are metamorphosed tholeitic dolerites, intrusive within the Triassic evaporites in remarkably abundant and large (kilometre-sized) sills and plugs, and alkali-basalt sills and plugs related to the Albian rifting. The ophites are considered to be related to the Triassic period of rifting[31] because they do not intrude younger formations. But this may result from the location of Triassic evaporites at the bottom of the troughs or to their mechanical properties; the ophites could be related to the Cretaceous rifting as suggested by other authors[32].

Discussion

A new analysis of the geophysical data on the Salton Trough and southern Red Sea rifts leads to the conclusion that after splitting of the continental crust a new lithosphere can be created with a metasedimentary section directly above the mantle formations and without a normal oceanic crust. The existence of this metamorphism is deduced from heat-flow data[8]. It is also imprinted in the Red Sea evaporitic sediments in contact with the Zabargad Island intrusion of hot spinel-feldspar lherzolites[33]. The metasediments are intruded by mafic sills and plugs[23]. In the Red Sea, there is a striking contrast between the style of mafic magmatism in the continental crust (Fig. 2*b*) and in the evaporitic sediments of the trough (Fig. 2*a*).

The Mesozoic Pyrenean troughs seem to represent a similar situation, at least in the western part where the continental disruption was probably complete, a stage not attained in the eastern part. This interpretation is supported by the comparative study of the intruded peridotite bodies.

The scenario proposed for the western Alps lherzolites[34] can be applied to spinel lherzolites from the eastern Pyrénées, which are very similar. They would be derived from a diapiric asthenosphere uprise below a continental rift. Because of a particularly slow ascent rate in relation to a presumed slow (<1 cm yr^{-1}) opening rate, the partially molten asthenosphere meets the thermal conduction front of the lithosphere during its ascent at ≈30 km, where the melts carried so far start crystallizing[34]. This explains the comparatively fertile character of the lherzolites, their equilibration in the spinel-lherzolite field, the limited amount of known associated magmatism and the low temperature characteristics of their subsequent plastic deformation, which records their further ascent and possibly the first stages of the rift closure. It has been proposed recently[35] that this lherzolite diapir has disrupted the continental crust and intruded through the rift sediments. This interpretation, proposed in the case of feldspar-lherzolites[34,36], seems unlikely for the spinel lherzolites considered here.

In the western Pyrénées, the occurrence of harzburgitic lherzolites is symptomatic of the creation of oceanic lithosphere[34] and of substantially larger spreading rates there than in the east[36]. In Boillot's model[26], it is possible to estimate the opening rate at ≈1.3 cm yr^{-1}, which is sufficient to generate an oceanic lithosphere in terms of the amount of melting (20%) and of the harzburgitic nature of the residual mantle[36]. However, the oceanic mantle would be directly overlain by metamorphosed sediments, as suggested by the absence of oceanic crust fragments associated with the harzburgite bodies. The large and numerous ophite intrusions could represent the mafic products generated by the mantle melting, but this would imply that they are not Triassic (see above). The extensive serpentinization of the harzburgite bodies, contrasting with its scarcity in eastern lherzolites, would be partly achieved at high temperatures by water contamination from the overlying metasediments and partly during and after the squeezing up of the peridotites through the trough's formation. This is recorded by the serpentinization sequence, showing first a high temperature alteration (antigorite–tremolite–chlorite), followed by a low temperature one (lizardite).

Such a partial and early serpentinization of the mantle section beneath metamorphosed sediments may explain the seismic and gravimetric data obtained in the Salton Trough[8]. In particular, the upper sub-basement could correspond there to a peridotite with 15–20% serpentine.

Conclusions

Based on the data presented here, I propose that in certain circumstances a new type of crust can be created during the rifting of a continent. During the disruption of the continental crust, this new crust would be composed of a thick sedimentary

sequence, metamorphosed at its base in the greenschist or the amphibolite facies depending on its thickness and be invaded by sills and plugs of kilometre-sized mafic intrusions. The immediately underlying anomalous mantle ($V_p \simeq 7.5$ km s^{-1}) would be composed of hot peridotites and/or of partially serpentinized peridotites. The latter interpretation agrees with the one proposed by Hess[37], in which a lower oceanic crust is formed by serpentinized peridotites. The formation of this special crust would require conditions in which the creation of a normal oceanic crust would be impossible. Such conditions could occur when the transition from continental to oceanic lithosphere occurs in a trough filled with a thick pile of young sediments, a situation opposed to that of a starved rift[1]. The basaltic magma released by the underlying mantle diapir into the immature sediments does not meet conditions to create a volcanic cap below which a plutonic section can fractionate. On the contrary, as already proposed by Saunders *et al.*[6], the magma reacts with these sediments and is frozen in them as sills and plugs, thus contributing to the metamorphism of the sediment. Dolerite and gabbro sills material and metamorphosed sediments have been recovered by DSDP drilling in the Gaymas Basin of the Gulf of California[6] which, as mentioned above, seems to correspond to an appropriate environment.

It may be of interest to contrast the situation on the Arabian edge of the Red Sea and in the trough itself (Fig. 2). On the edge, the disruption of the continental crust with a little and old sedimentary cover leads directly to the creation of typically ophiolitic segments of oceanic crust, whereas in the trough where young and wet sediments have accumulated, the geophysical record does not show the existence of such oceanic crust but suggests a direct contact between sediments and serpentinized mantle.

Heritable formation of pancreatic β-cell tumours in transgenic mice expressing recombinant insulin/simian virus 40 oncogenes

Douglas Hanahan

Cold Spring Harbor Laboratory, Cold Spring Harbor, New York 11724, USA

Following the transfer into fertilized mouse eggs of recombinant genes composed of the upstream region of the rat insulin II gene linked to sequences coding for the large-T antigen of simian virus 40, large-T antigen is detected exclusively in the β-cells of the endocrine pancreas of transgenic mice. The α- and δ-cells normally found in the islets of Langerhans are rare and disordered. Well-vascularized β-cell tumours arise in mice harbouring and inheriting these hybrid oncogenes.

INSULIN, a polypeptide hormone involved in the control of carbohydrate metabolism, is synthesized and stored in the β-cells of the endocrine pancreas, from which it is released into the bloodstream in response to various signals. The endocrine pancreas is comprised of isolated islands or islets, which are dispersed throughout the larger mass of the exocrine pancreas; the islets consist of four major cell types, α, β, δ and PP, which synthesize the hormones glucagon, insulin, somatostatin and pancreatic polypeptide, respectively[1,2]. Rat and human insulin genes have been cloned and analysed[3–13]. There are two non-allelic rat insulin genes that differ in nucleotide sequence and in the number of introns; the rat insulin I and II genes have one and two introns, respectively[5,6]. The two genes share a region of considerable sequence homology in the 5′ flanking region, extending ~300 base pairs (bp) upstream of the point of transcriptional initiation[12]; the human gene is 75% homologous over the first 240 bp of this region[8]. Expression of hybrid genes using the 5′ flanking regions of both the human insulin and rat insulin I genes occurs when they are introduced transiently into cultured cells derived from an insulinoma[11].

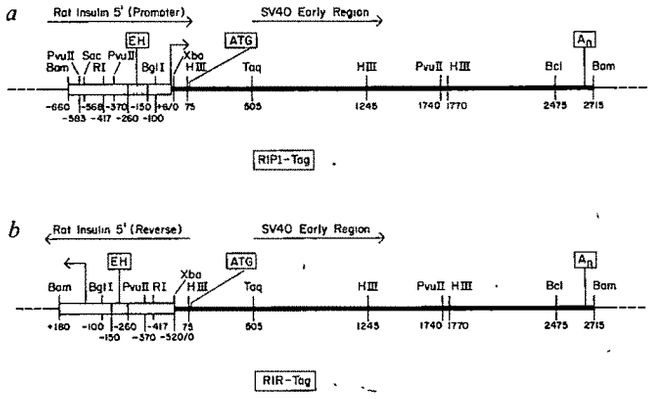

Fig. 1 Structure of recombinant insulin/large-T antigen genes. The plasmids pRIP1-Tag (*a*) and pRIR-Tag (*b*) consist of the coding information of the SV40 early region fused to sequences derived from the 5′ flanking region of the rat insulin II gene. Boxed regions denote insulin gene flanking DNA and the thick solid line refers to the SV40 early region. The cap site where insulin gene transcription initiates is indicated by an L-shaped arrow, and the associated transcriptional enhancer element[11] (EH) is shown (the insulin gene promoter, which lies between them, is not indicated). The points of SV40 large-T antigen translation initiation and transcription termination are indicated by boxed ATG and A_n respectively. The *Bgl*I site in SV40 was converted to an *Xba*I site using an oligonucleotide linker, and the *Xba*/*Bgl*I to *Bam* fragment comprising the SV40 early region[24] was linked to two different orientations of the insulin gene flanking region. This fragment of the SV40 early region includes the early mRNA cap sites, but lacks all known components of the SV40 early promoter. For *RIP1-Tag*, an *Xba* linker was inserted into the *Dde*I site at +8 bp relative to the point of initiation of insulin gene transcription, and the *Bam* to *Dde*/*Xba* fragment from −660 to +8 was combined with the *Xba*/*Bam* fragment of the SV40 early region and inserted as a *Bam* linear into a derivative of pBR322 that lacks the R1 site, and includes a *lacUV5* promoter in place of the R1 to *Bam* fragment of pBR. For the plasmid pRIR-Tag, which carries the insulin flanking region in the opposite orientation, a *Dde* site at −520 was converted to an *Xba* site, and the *Bam*/*Xba* fragment extending from +180 nucleotides past the cap to −520 bp upstream was combined with the structural gene for large-T antigen and inserted into the same plasmid vector. The two hybrid genes were similarly prepared for microinjection, except that for *RIR-Tag*, the *Bam* insert was first purified from the plasmid vector by gel electrophoresis and electroelution, followed by passage over a DEAE-Sephacel column and pRIP1-Tag was linearized using *Sal*I. The DNAs were extracted with phenol, chloroform, precipitated in 70% ethanol, resuspended in 10 mM NaCl, 5 mM Tris *p*H 7.4, 0.1 mM EDTA and passed through a 1-ml spin column of Sepharose CL6B, after which the DNA was diluted to concentrations of ~75 copies per pl for pRIP1-Tag/*Sal* or ~20 copies per pl for the *RIR-Tag*/*Bam* insert. The DNAs were injected into fertilized one-cell embryos essentially as described[14,16], except that the injected embryos were cultured overnight to the two-cell stage before being re-implanted into the oviducts of pseudopregnant females. The F_2 embryos were derived from matings of B6D2F1 (C57BL/6J × DBA/2J) males and females, obtained from the Jackson laboratory.

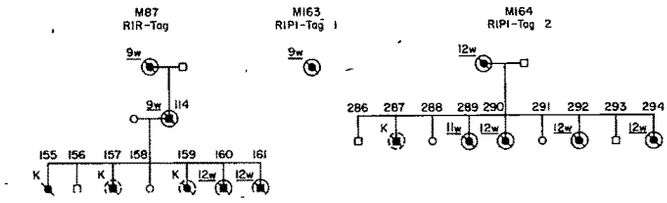

Fig. 2 An early pedigree of insulin/large-T antigen transgenic mice. A partial pedigree analysis is presented, to examine the heritability of the phenotype of premature death and islet hyperplasia. Females are indicated by open circles, males by open squares and transgenic mice by solid circles and squares. The circled slash denotes premature death, with the age at death shown in weeks (w). A slash alone with a superscript K indicates the animal was killed and the dotted circle around a killed mouse denotes evidence of islet hyperplasia following histopathology. (M155 was killed but not examined for hyperplasia.) Each original transgenic mouse is assigned a genotype consisting of the name of the gene that was injected and acquired followed by a number which distinguishes it from the other independent mice carrying the same gene. Therefore, progeny of a particular mouse can be readily identified as such (for example, all mice of genotype *RIP1-Tag2* are progeny of the original transgenic mouse 164).

Fig. 3 (Opposite) Histology and pathology of normal and insulin/T-antigen transgenic mice pancreas. *A*, Cresol violet-stained sections of a normal pancreas and a pancreas derived from a transgenic mouse bearing solid tumours. *a*, Normal (non-transgenic) pancreas with a single islet in the centre and an adjacent blood vessel (×50). *b*, Part of a solid tumour (one of those pictured below) near two normal-sized islets (at the top) in M384 of the *RIP1-Tag2* line (×50). *c*, A normal-sized islet from a non-transgenic mouse (×200). *d*, A normal-sized transgenic islet (from *b*) (×200). In all cases, exocrine cells show purple cytoplasmic staining with somewhat deeper-coloured nuclei, whereas endocrine cell nuclei stain dark violet with minimal cytoplasmic staining. Note the denser packing of nuclei in all sizes of islets derived from the transgenic mouse relative to the normal mouse islet. Compare the normal islet in *a* with the two small islets near the top of *b* and the higher magnifications in *c* and *d*. The extent of cytoplasmic staining observed in the exocrine tissue varies with the length of time the sections were stored before treatment with cresol violet. *B*, Comparison of a whole pancreas from a normal mouse (*a*) with that of M384 (*b*), showing several vascularized solid tumours in the transgenic pancreas (×25).

Methods. Sections (14 μm) were taken on a cryostat from pancreas flash frozen in liquid nitrogen, stored at −70 °C and then mounted in tissue Tek OCT embedding medium and sectioned at −20 °C on to gelatinized microscope slides. The sections were fixed for 10 min in 4% paraformaldehyde in phosphate-buffered saline (PBS), washed in PBS and air dried. Sections were then rehydrated in PBS, treated in filtered cresol violet for 2 min, washed for 5 min in two changes of 70% ethanol, then washed twice for 2 min each in 90% ethanol, 100% ethanol and xylene and then mounted under coverslips in Gurr Fluromount. The cresol violet solution consists of 0.25% (w/v) thianin that had been dissolved by heating in 200 mM hydroxyacetate plus 26 mM NaOH and stored at 50 °C.

Here I seek to address aspects of insulin gene expression by the introduction of recombinant insulin genes into the mouse germ line, using microinjection of DNA into fertilized mouse embryos. This technique has been used previously to examine the control and consequences of expression of a number of genes[14–23], including two oncogenes. The complete simian virus 40 (SV40) early region, including the viral transcriptional enhancer and promoter, is not expressed at detectable levels in normal tissues of transgenic mice harbouring it, but choroid plexus tumours heritably arise, and these tumours produce high levels of large-T antigen[19]. The cellular proto-oncogene c-*myc*, when linked to the long terminal repeat of mouse mammary tumour virus, is expressed in a number of tissues, including mammary cells, and two lines of mice heritably develop breast tumours[20].

The recombinant oncogenes used here consist of regulatory information associated with the rat insulin II gene linked to protein coding information for the oncogene SV40 large-T antigen (Tag). The rationale for using such a hybrid is threefold: (1) to examine the ability of the insulin sequences to mediate correct tissue- and cell-type specific expression in the β-cells of the endocrine pancreas, using a readily identified and distinguishable marker protein (a viral antigen); (2) to examine the consequences to the organism of tissue-specific expression of an oncogene, in particular the possibility that SV40 large-T antigen might induce β-cell proliferation and consequent oncogenesis; and (3) to assess the prospects that oncogenes can be used to facilitate the establishment of stable cell lines from rare cell types specifically expressing such fusion genes. This report describes analyses pertaining to the first two of these questions.

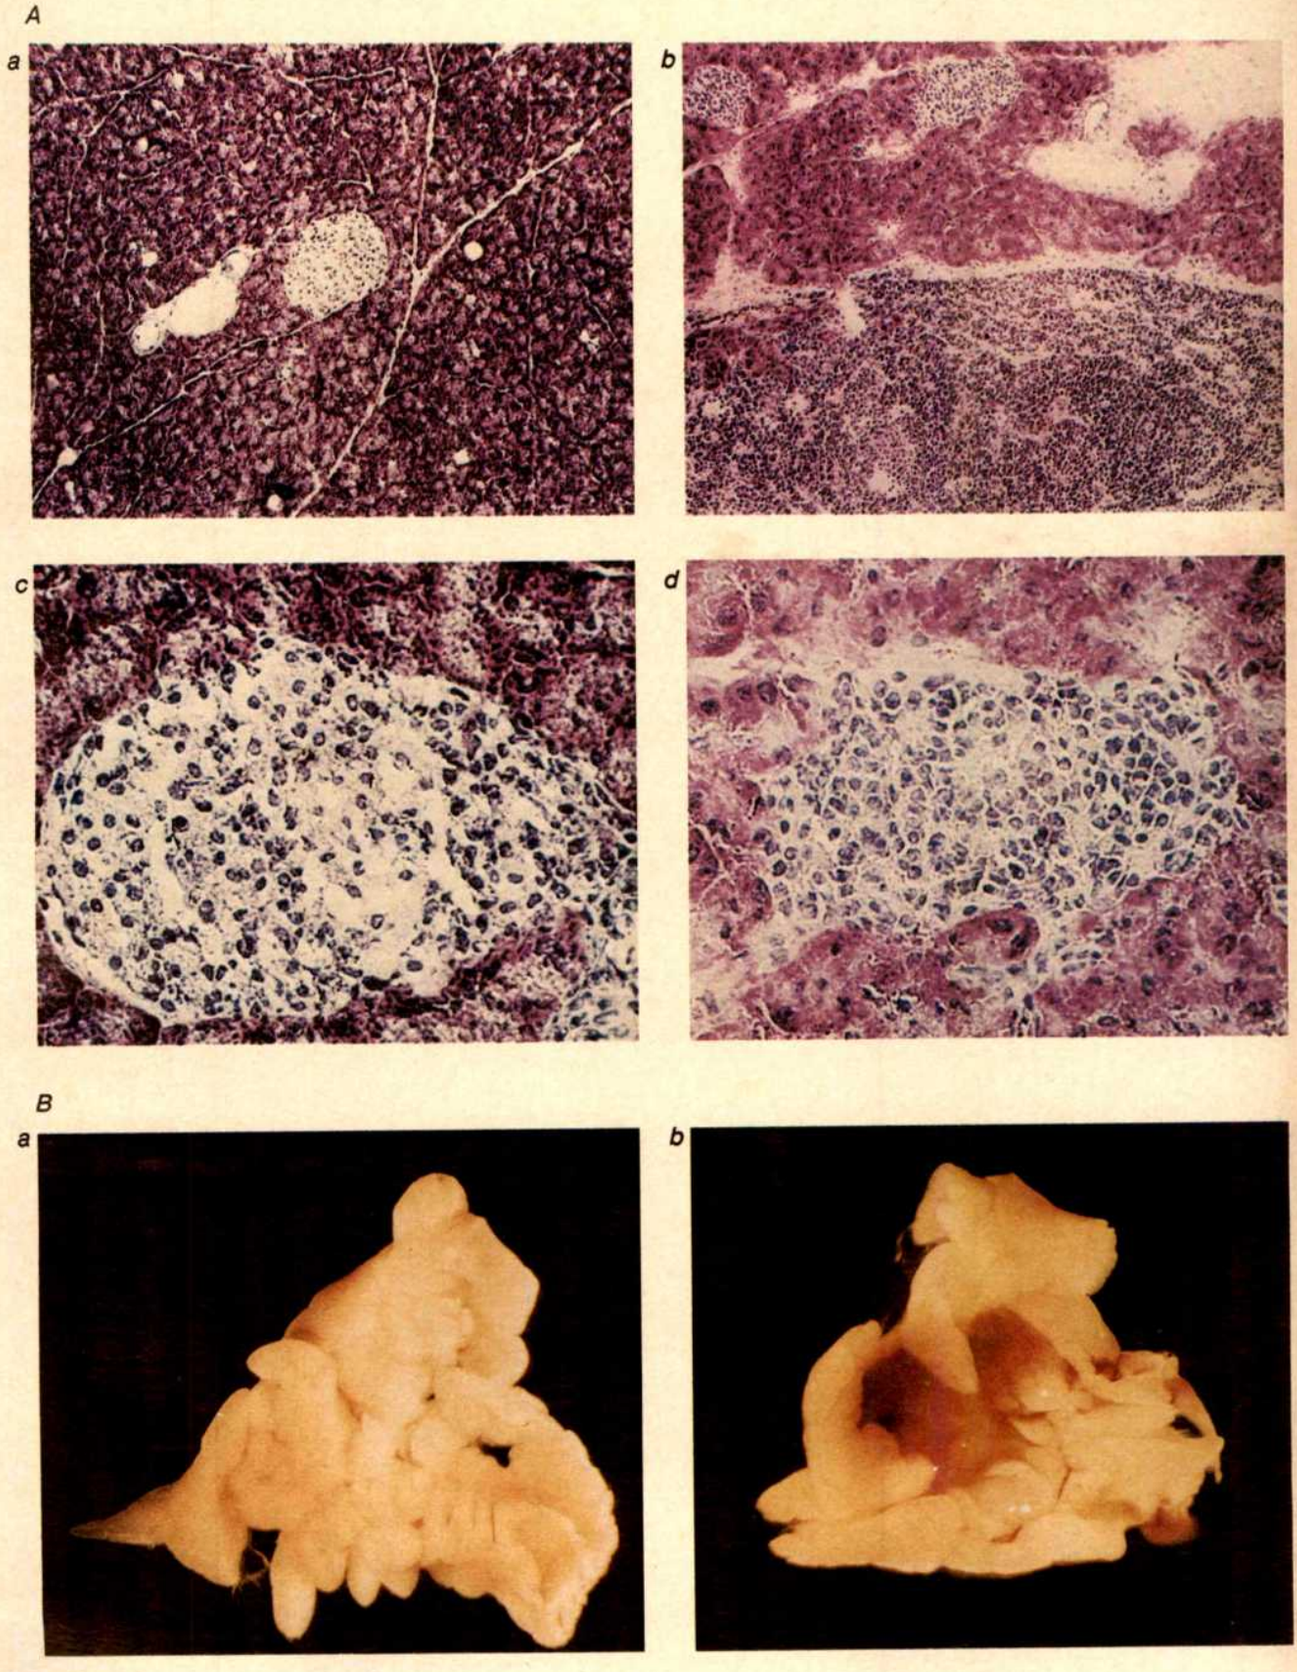

Fig. 3

Hybrid gene constructs

Two hybrid genes were constructed to combine DNA 5′ to the coding sequences of rat insulin II gene with the large-T antigen structural information. This 5′ flanking region includes the insulin gene promoter as well as a transcriptional enhancer element that stimulates initiation of transcription in cultured insulinoma cells but not in fibroblasts[11]. The first configuration, denoted *RIP1* (rat insulin promoter 1) carries the insulin control region aligned to promote transcription of the large-T antigen gene (Fig. 1). The two genes were linked together in regions corresponding to the 5′ untranslated portion of each messenger RNA. The resulting hybrid gene, *RIP1-Tag*, thus comprises a complete transcription unit with 660 bp of sequence located 5′ to the point of transcriptional initiation of the insulin gene linked to protein coding and termination information from the early region of SV40.

The second configuration, denoted *RIR-Tag* (rat insulin reverse), includes 520 bp of DNA 5′ to the insulin gene and the first 180 bp of the transcribed portion of the gene. In this hybrid, the promoter element for insulin gene transcription is inverted with respect to the coding information for SV40 large-T antigen, and, therefore, does not comprise a fusion in the 5′ untranslated regions of the two genes, but rather includes an inverted promoter and enhancer region linked to the *Tag* structural gene, as shown in Fig. 1. Both hybrid genes lack the SV40 early promoter and transcriptional enhancer element, and each includes protein coding information for SV40 small-T antigen, as well as for large-T, because the two proteins are derived from the primary transcript of the SV40 early region by differential splicing of overlapping introns[24].

The two fusion genes were injected into fertilized one-cell mouse embryos, which were then inserted into the oviducts of pseudopregnant female mice and allowed to develop. Four transgenic mice were produced from the *RIP1-Tag* injections and one from the *RIR-Tag* injections. The apparent heterozygous copy number (per diploid genome) of the acquired DNA ranged from ~1 for mouse 87, which carries *RIR-Tag*, to ~5 for mouse 163, which carries and is genotyped as *RIP1-Tag1*, and 5 for mouse 164 (*RIP1-Tag2*). Two of the founder mice (165 and 168) were mosaic for the acquired transgene, using the criteria of infrequent transmission to progeny and lower apparent copy number in the founder than in its progeny. The non-mosaic progeny of M165 (*RIP1-Tag3*) have copy numbers of ~25, whereas those of M168 (*RIP1-Tag4*) have ~12 copies per diploid genome. In each case of multiple copies, genetic and biochemical analysis indicates that the genes are heterozygous and integrated in a single location (data not shown).

Phenotype of transgenic mice

During the initial breeding analysis of the insulin large-T antigen transgenic mice, a phenotype of premature death emerged. The three original non-mosaic mice died at 9-12 weeks of age. Two of these transmitted the transgene to offspring before dying, whereas the third (M163) did not. Surprisingly, this phenotype appeared with the *RIR-Tag* gene, which has the insulin promoter inverted with respect to the large-T antigen coding region, as well as with the *RIP1-Tag* gene, in which the insulin promoter is aligned to transcribe the large-T antigen gene.

The phenotype of premature death proved to be heritable and co-segregated with the acquired hybrid gene; the partial pedigree in Fig. 2 illustrates this observation. The penetrance is virtually complete in the early generations. The analysis that follows deals primarily with the progeny of the two original non-mosaic mice that transmitted—M164 (*RIP1-Tag2*) and M87 (*RIR-Tag*). Progeny of each were killed and subjected to pathological and biochemical analysis. The only obvious abnormal pathology consisted of hyperplasia of the islets of Langerhans, determined following standard histochemical staining of tissue sections. Solid tumours were observed in a few of these mice. Figure 3*a* shows representative pancreas sections of a normal mouse and of a transgenic mouse (M384, *RIP1-Tag2*) that carried visible tumours; both were ~12 weeks old. Sections were stained with cresol violet, which distinguishes the endocrine islets from the surrounding exocrine tissue. Sections from M384 showed normal-sized islets, enlarged (hyperplastic) islets and solid tumours. All stained with similar characteristics, and were identifiable as islet-like regions by comparison with normal islets. Note, however, that all islet-like areas in the transgenic mouse appear more densely packed with cells than do the normal mouse islets, demonstrated by comparison of Fig. 3*A c* and *d*.

Analysis of the mice listed in Fig. 2 shows that all transgenic mice in these two lineages have the phenotype of islet hyperplasia (if killed) and/or premature death. Before their sudden death, the mice seem normal in appearance and activity. The pedigree stops at the generation during which the mice were placed on a high sugar diet to counteract indications that they were hypoglycaemic, which is a probable consequence of islet hyperplasia, and a possible cause of sudden premature death. Subsequent generations, maintained on this diet, now live somewhat longer and heritably develop solid tumours of the pancreas between 10 and 20 weeks of age. An example of a pancreas containing several tumours is shown in Fig. 3*B*. These tumours eventually comprise a significant fraction of the mass of the pancreas and are highly vascularized. Individual tumours can reach a size of 5 mm in diameter, with up to five or six separate tumours visible in a pancreas. There is no indication that the tumours metastasize other organs.

Cell-type specificity

To evaluate the observed hyperplasia of the islets of Langerhans, I examined normal and transgenic mouse pancreas for expression of both SV40 large-T antigen and polypeptide hormones characteristic for the major cell types. Thin sections were prepared from fresh frozen pancreas obtained from two transgenic mice (M384, *RIP1-Tag2*, and M306, *RIR-Tag*) carrying visible pancreatic tumours as well as from a normal mouse. The sections were analysed by immunostaining using antisera to glucagon, insulin and somatostatin and each visualized with rhodamine-conjugated second antibody to identify the α-, β- and δ-cell types of the islets. Large-T antigen was identified using both a polyclonal antiserum and monoclonal antibodies, each visualized by horseradish peroxidase-conjugated second antibody. Figure 4*a* shows representative immunostains of normal (non-transgenic) islets for the presence of insulin, large-T antigen, glucagon and somatostatin. The islets are comprised predominantly of α- and β-cells with fewer δ-cells; no cells react with antibodies to large-T antigen. Controls using second antibodies alone show no specific staining (not shown).

The islet tumours (Fig. 4*b*, *c*) in contrast, seem to consist of solely of insulin-producing cells, identifiable as β-cells by immuno- and histochemical staining. Glucagon- and somatostatin-producing cells are rare if not completely absent from the tumours. Characteristic localization of large-T antigen to the nucleus is observed in the islet tumour cells; it is clearly absent from adjacent exocrine cells. Evidence from both polyclonal serum (shown) and monoclonal antibodies (not shown) indicates the same pattern of large-T antigen expression. By these criteria, the islet tumours are essentially pure populations of proliferating β-cells. Occasional clusters of α-cells, perhaps remnants of an islet, can be detected on the edges of a tumour. Thus, both hybrid oncogenes specifically induce proliferation of the β-cells of the islets of Langerhans, eventually resulting in the appearance of pure β-cell tumours. In comparison, naturally occurring insulinomas are characteristically a mixed population of both β- and δ-cells, producing insulin and somatostatin, respectively[25,26].

Tissue-specific expression

The ability of the insulin control region to mediate tissue-specific expression of the SV40 large-T antigen following integration of the hybrid genes into the mouse germ line was assessed by

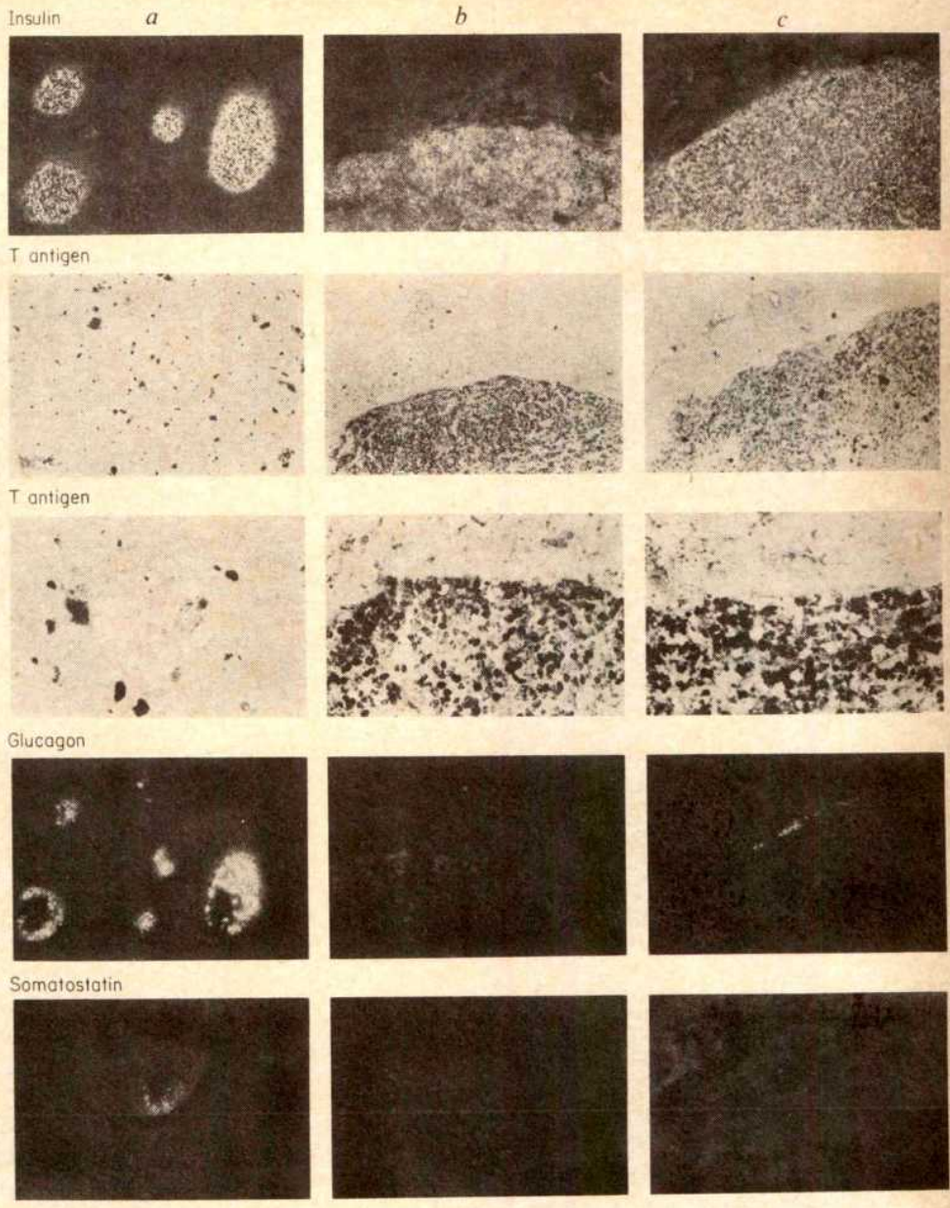

Fig. 4 Analysis of islet cell hormone and large-T antigen expression in a normal mouse and two tumour-bearing transgenic mice. Each column shows an analysis of one mouse: *a*, normal (non-transgenic); *b*, 384 from the *RIP1-Tag2* line; *c*, 306 from the *RIR-Tag* line. In each case, near (but not necessarily adjacent) thin sections were analysed for the presence of the specified antigen by using an antiserum to that antigen followed by a conjugated second antibody to visualize the first. The first row examines insulin, the second and third rows large-T antigen, the fourth row glucagon and the fifth row somatostatin. Magnification is ×50 except for the third row, which is ×200. The use of second antibodies alone gives no specific staining. In *a*, insulin and glucagon plates are of the same cluster of islets, whereas the somatostatin and large-T antigen are of other islets, because that cluster was not present in those sections. The immunostains for the hormones were visualized with rhodamine-conjugated second antibody and epifluroscent illumination, whereas the immunostain for large-T antigen used peroxidase-conjugated second antibody, and was viewed under bright-field illumination. *b*, *c*, Orientation of all the plates is the same. The islet tumour is on the bottom, with adjacent exocrine tissue above it. Column *b* is aligned so the tumour is a centred arc, whereas the plates in *c* have the tumour ascending to the right. The glucagon and somatostatin plates of *b* and *c* are of sections near those used for insulin and large-T antigen; the outline of the exocrine/tumour boundary can be seen in each. The ×200 plates of large-T antigen also show an exocrine/tumour boundary, in which peroxidase staining occurs in nuclei in the tumour tissue but not in the exocrine tissue.

Methods. 14-μm sections were taken as described in Fig. 3 legend, except that for the large-T antigen immunostaining the sections were not fixed, but rather air dried on gelatinized slides. The hormone immunostains were performed on paraformaldehyde-fixed sections as in Fig. 3. Sections were rehydrated in Net-Gel (150 mM NaCl, 5 mM EDTA, 50 mM Tris *p*H 7.4, 0.25% gelatin, 0.02% NaN_3, 0.05% NP40), then treated for 30 min in blocking solution (45% Net-Gel, 45% Dulbecco's modified Eagle's medium, 10% fetal bovine serum, 1% bovine serum albumin (BSA), 0.5% NP40). The sections were then incubated overnight at room temperature in the first antibody, in a binding solution (blocking solution without BSA), washed several times for 30 min in Net-Gel, incubated with second antibody in binding solution for 3 h at room temperature, and again washed in several changes Net-Gel. The sections treated with rhodamine-conjugated second antibody were taken through graded alcohol into xylene and mounted under coverslips in Gurr Fluromount+2% diazabicyclooctane. The large-T antigen sections were visualized with horseradish peroxidase-conjugated second antibody, which was developed by treatment for 10 min in 0.25 mg ml^{-1} diaminobenzidine, 3 mg ml^{-1} nickel sulphate, 0.003% H_2O_2. The slides were then washed several times in Net-Gel and mounted. The antisera, sources and dilutions are as follows: guinea pig anti-porcine insulin (gift of R. Santerre) 1:5,000; rabbit anti-large-T antigen (a gift of D. Lane) 1:2,000; rabbit anti-human glucagon, Dako A565, 1:1,000; rabbit anti-human somatostatin, Dako A566, 1:1,000; horseradish peroxidase-conjugated swine anti-rabbit IgG, Dako P217, 1:200; rhodamine-conjugated goat anti-guinea pig IgG, Capel 2207-0081, 1:200; rhodamine-conjugated sheep anti-rabbit IgG, Capel 2212-0084, 1:200.

protein blotting analyses, using monoclonal antibodies that specifically recognize large-T antigen. Figure 5*a* presents a comparison of pancreas from several mice, including one normal (non-transgenic) mouse, several insulin/large-T antigen transgenic mice, and one carrying a collagen/large-T antigen fusion gene (M410) which therefore lacks the insulin gene sequences (D.H., unpublished results). M287 and M289 are siblings in the *RIP1-Tag2* lineage (see Fig. 2); M287 had large solid tumours whereas M289 did not, which illustrates the difference in levels of expression observed in mice of the same age and genotype with and without solid tumours. M277 contains immunoprecipitable large-T antigen, demonstrating that the *RIP1-Tag3* lineage derived from the founder M165 also expresses the fusion gene. Large-T antigen is not detectable in a normal (F_1) pancreas or in the transgenic mouse (M410) that lacks the insulin gene regulatory region. The *RIR-Tag* transgenic mouse 155 does not show expression in the blot demonstrated here, but other analyses show a low level of large-T antigen. The *RIP1-Tag4* lineage, exemplified here by M274, does not show detectable expression of large-T antigen by protein blotting. However, pancreatic tumours occasionally arise in this line, which indicates that the *RIP1-Tag4* insertion can express.

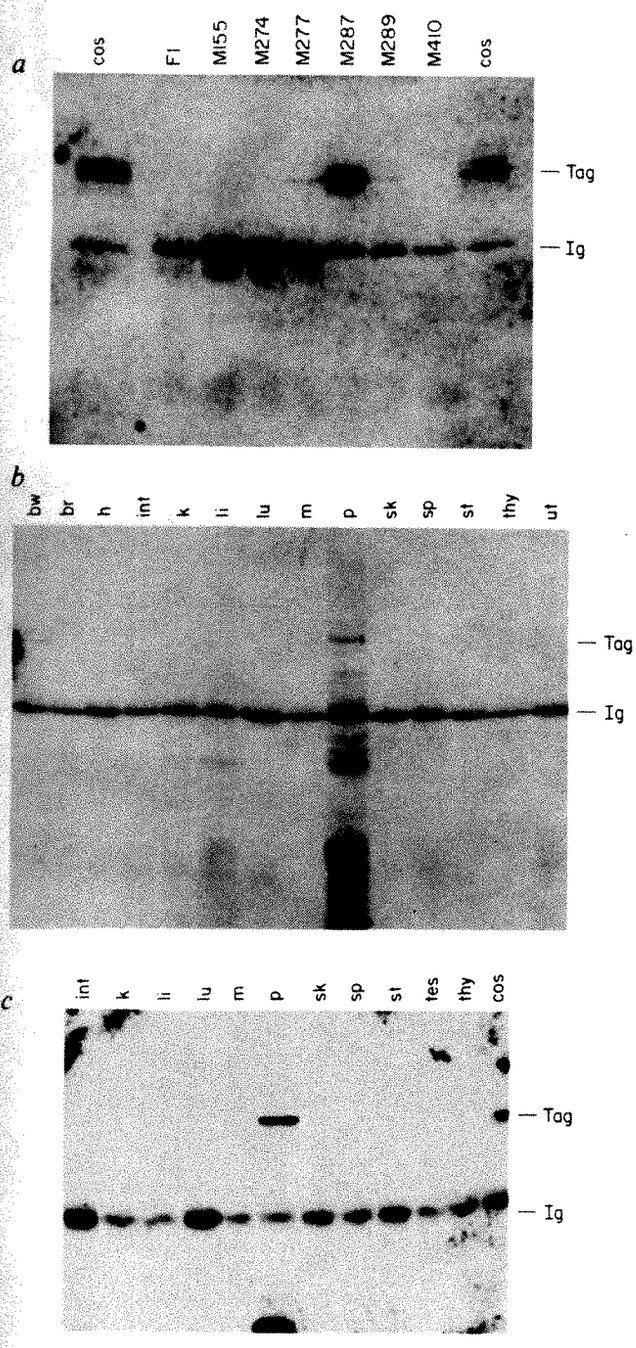

Fig. 5 Tissue specificity of transgene expression. The presence of SV40 large-T antigen in tissues was evaluated by protein blotting[39,40], in which tissue homogenates were immunoprecipitated with a monoclonal antibody (PAb 419) (ref. 41) to T antigen, fractionated on a 10% SDS-polyacrylamide gel, transferred to nitrocellulose by electroblotting and visualized with a second radiolabelled monoclonal antibody (PAb 416), which recognizes a different epitope on the protein[41]. *a*, Pancreas from several mice are compared. F_1 is a non-transgenic mouse, M155 an *RIR-Tag* transgenic, M274 is *RIP1-Tag4*, M277 is *RIP1-Tag3*, M287 and M289 are from siblings from the *RIP1-Tag2* lineage, with M287 having visible tumours and M289 only hyperplastic islets, and M410 is a mouse harbouring a type I collagen/SV40 large-T antigen fusion gene. To provide a control of authentic large-T antigen, total protein from a lysate of the SV40-transformed monkey cell line cos A2 (ref. 42) was immunoprecipipitated and similarly treated, except that only 5% as much protein was used compared with the amount of pancreas protein. *b*, *c*, Tissue specificity of large-T antigen expression in the *RIP1-Tag2* (*c*) and *RIP1-Tag3* (*b*) lineages. Equal concentrations of each tissue were examined: bw, body wall; br, brain; h, heart; int, intestine; k, kidney; li, liver; lu, lung; m, muscle, p, pancreas; sk, skin, st, stomach; tes, testes; thy; thymus; ut, uterus. A separate analysis indicates that no large-T antigen can be detected in body wall, brain or heart of M287 (not shown). The radiolabelled antibody PAb416 sticks to the vast excess of immunoglobulin protein used in the immunoprecipitation, thus generating a band of relative molecular mass 55,000 in all samples. This band is further identifiable as IgG using either radiolabelled protein A or rabbit anti-mouse IgG.

Methods. Tissues were flash frozen in liquid nitrogen, stored at −70 °C, and then homogenized in 50 mM Tris *p*H 7.2, 5 mM $MgCl_2$, 1 mM $CaCl_2$, 10 mM dithiothreitol, 1% NP40, 100 μg ml^{-1} DNase I, 50 μg ml^{-1} RNase A, 75 μg ml^{-1} phenylmethylsulphonyl fluoride. Protein concentrations were determined using the Bio-Rad protein assay reagent. 500 μg of tissue protein or 25 μg of cos cell protein was incubated overnight at 4 °C with 100 μl of tissue culture supernatant containing the monoclonal antibody PAb419, and then precipitated with 100 μl of 3% protein A-Sepharose (Pharmacia) for several hours. The immunoprecipitate was fractionated on a 10% SDS-polyacrylamide gel, transferred to nitrocellulose by electroblotting overnight, incubated first in a blocking solution (Fig. 4) for 12 h and then in a binding solution (Fig. 4) containing 10^5 c.p.m. ml^{-1} of PAb416, which had been radiolabelled with ^{125}I using the chloramine-T method. The blots were washed in Net-Gel and exposed with intensifying screens onto Kodak XAR film.

The tissue specificity of fusion gene expression was evaluated further by comparing a number of different tissues from two mice (Fig. 5*b*, *c*), progeny of the two founders M164 and M165. Both show tissue-specific expression of SV40 large-T antigen, as only pancreas is producing immunoprecipitable protein that co-migrates with authentic large-T antigen. Some degradation of the antigen in pancreatic tissue is observed routinely; it is not clear whether this represents a normal situation in the β-cells or is simply a consequence of the protein isolation procedure. Analysis of a mouse from the *RIR-Tag* lineage also shows expression only in the pancreas, as does a similar examination of the tissues of mouse 163 (*RIP1-Tag1*) (not shown). In a normal pancreas, insulin-producing β-cells comprise only ~1-2% of the total cell mass[1,2]. Therefore, a lower limit can be established for inappropriate expression: either <~1% of the cells in another tissue could be expressing at levels comparable with those in β-cells, or all the cells in an inappropriate tissue could be expressing at levels of <1% of those observed in the islet cells. Within these limits, the expression of both insulin/large-T antigen hybrid genes is tissue specific to the pancreas. Taken together with the immunohistochemical analysis, the transferred insulin sequences are specifying correct expression in the β-cells of the endocrine pancreas.

Penetrance and the onset of oncogenesis

The relationship between large-T antigen expression and the development of β-cell tumours bears on possible mechanisms for oncogenesis. The two previous examples of oncogene expression in transgenic mice give contrasting results[27]. An apparently dormant SV40 early region is activated to express at high levels, and frequently amplified, in the development of choroid plexus tumours[19]. In contrast, a murine mammary tumour virus *myc* fusion gene is expressed in all mammary glands and in several other tissues before oncogenesis, which occurred in only 1 of the 10 mammary glands, implying that a secondary event is required to elicit tumour development[20]. In the insulin/large-T antigen transgenic mice examined to date, a similar pattern emerges. No more than 4 or 5 of the ~100 islets in a pancreas develop into solid β-cell tumours, which are highly vascularized and readily distinguishable from normal pancreatic tissue (Fig. 3*B*). Yet most islets show hyperplasia and all islets examined have increased β-cell density. Furthermore, the β-cells seem to be expressing the hybrid genes well before the development of hyperplasia and tumours, as is demonstrated in an examination of the pancreas from an 8-week-old mouse (M633) in the *RIP1-Tag2* lineage. This mouse exhibited normal pathology and histology, in particular showing no hyperplasia or visible tumours in the pancreas. Thin sections were prepared from the pancreas and stained with antibodies

for insulin and large-T antigen; a representative analysis of a pair of islets is shown in Fig. 6. Large-T antigen is expressing in both of these islets, as well as in all other islets examined in this pancreas. Thus, large-T antigen is expressing in the β-cells of a young mouse before emergence of obvious hyperplasia and solid tumours.

The interpretation of these observations is that the hybrid insulin/large-T antigen genes are expressed in all β-cells, thereby inducing their prolifieration, which leads to initial hyperplasia followed by oncogenic transformation. The development of solid tumours occurs in only a few of the islets, which indicates that additional events are probably necessary to mediate the rapid proliferation and extensive vascularization characteristic of the β-cell tumours. It will be of interest to distinguish between two possible classes of transformation: (1) an islet-specific change which affects most of the β-cells in an individual islet; and (2) a rare cell alteration that then produces a clonal tumour arising from that one altered cell.

Cell–cell interaction

Examination of the distribution of cell types in islets of these transgenic mice shows that islets of every size class (small, normal, enlarged, tumour) are densely packed with β-cells. Furthermore, the α- and δ-cells are disordered and rare. Comparison of the glucagon immunostains of normal islets (Fig. 1) and islets of the young transgenic mouse 633 (Fig. 6) shows that the characteristic peripheral distribution of α-cells has been disrupted and that their total number is reduced. Similarly, the normal polar organization of δ-cells is disordered and the δ-cell number severely retarded. This applies to every islet examined in this pancreas, in analyses that included sections taken to include different anatomical regions. These results suggest that during biogenesis of the islets, the α- and δ-cells are either sterically excluded or specifically suppressed by the altered β-cells.

Conclusions

The results presented here demonstrate that DNA within 520 bp upstream of the rat insulin II gene is sufficient to mediate qualitatively correct tissue- and cell-type-specific expression of hybrid insulin/SV40 large-T antigen genes. Protein blotting analysis of four mice harbouring independent insertions of such genes demonstrates expression only in the pancreas among the major tissues examined. The *in situ* analyses of thin sections from the pancreas demonstrates that this expression is cell-type specific, as large-T antigen is only detected in the insulin-producing β-cells of the islets of Langerhans.

The specification of tissue- and cell-type expression by the insulin gene 5′ flanking region occurs in both possible orientations when it is located upstream of the large-T antigen structural gene. Both tissue specificity and bidirectionality are qualities previously associated with transcriptional enhancer elements using transfection of cultured cells[28,29]. It is not clear whether this flanking region carries an additional real or cryptic promoter element oriented away from the insulin gene, or whether non-specific initiation of transcription is occurring in the *RIR-Tag* hybrid gene. RNA analyses will be necessary to address these possibilities.

There are three phases to the phenotype elicited by these hybrid oncogenes: the development of disordered islets, the subsequent enlargement of those islets into obvious hyperplasia and the formation of solid tumours. In young mice, the islets are of normal size, but densely packed with β-cells. The organization of both α- and δ-cells is disrupted and numbers of each severely reduced, δ-cells being particularly rare. These results suggest that islet cells interact to maintain a proper balance, and the transgenic β-cells effectively reduce α- and δ-cell number and organization by retarding their normal cell development. This possibility motivates a similar examination of the distribution of PP cells in the islets and islet tumours of these mice, because PP cells, like δ-cells, are often found at significant levels in naturally occurring insulinomas.

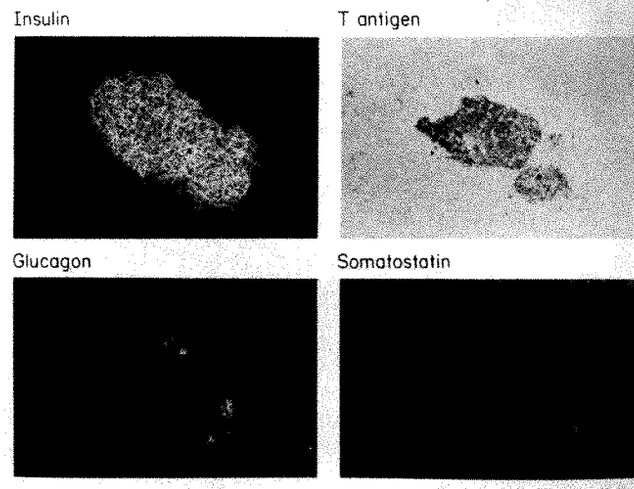

Fig. 6 Immunohistology of islets in the pancreas of a young transgenic mouse. Mouse 633, from the *RIP1-Tag2* lineage, was killed at 8 weeks of age and its pancreas flash frozen in liquid nitrogen, sectioned in a cryostat and analysed for the expression of islet cell hormones and large-T antigen as described in Fig. 4. legend. The two islets shown are representative of all islets in these and other thin sections from this pancreas. The sections used for insulin on large-T antigen are near but not adjacent and the islet sizes have changed somewhat across that distance (×50).

The prospect of disruption in islet-cell interactions is intriguing in view of observations that each of the three hormones influences secretion of the other two by their respective cell types. Somatostatin inhibits the release of both insulin and glucagon, insulin inhibits the release of glucagon and somatostatin, whereas glucagon stimulates secretion of insulin and somatostatin (see, for example, ref. 30). The organization of the endocrine pancreas into separate islands has led to suggestions that the islet cells arise from a common stem cell[31,32]. The character of the alterations in islet composition produced by the insulin/large-T fusion gene should allow more detailed examination of islet biogenesis. If islet cell types are interacting through growth factors, the results presented here suggest that they are probably suppressors of cell growth rather than inducers. Insulin itself is one candidate for such a suppressive growth factor.

The dense packing and disorganization of islets is followed by their expansion (hyperplasia), which seems to be a direct consequence of the expression of large-T antigen. Preliminary analysis indicates that serum insulin levels are elevated (two- to ten-fold), but not in proportion to the increased number of insulin-producing cells (>100-fold), which implies that either normal regulation of insulin secretion remains in effect, or that the β-cell structure, organization and/or vascularization is inappropriate for effective secretion. Isolation of β-cell lines from these transgenic mice should be facilitated by the ability of large-T antigen to establish (or immortalize) primary cells to growth in culture, with large-T antigen synthesis here maintained by the co-expression of the insulin and insulin/large-T antigen genes in β-cells. The availability of such β-cell lines will allow more detailed examination of the characteristics of altered β-cells. We may now examine how islet disorganization is correlated with changes in glucagon, somatostatin and insulin serum levels over a detailed timescale. It seems likely that the mice described in this study suffer from serious alterations in regulation of carbohydrate metabolism and that the explanation of their premature death does not simply result from excessive insulin in their serum, but also involves other factors.

Solid β- cell tumours eventually develop from a few of the hyperplastic islets. Tumour development occurs between 10 and 20 weeks of age, is heritable and has occurred in all progeny of the two lines (*RIP1-Tag2* and *RIR-Tag*) in which mice have lived to this age, and is occurring now in the *RIP1-Tag3* line. The solid tumours are frequent in the sense they arise in every

mouse harbouring these genes, although they occur only in a fraction of the islets. The characteristics of tumour formation suggest that synthesis of large-T antigen is necessary but insufficient to produce that condition in every islet. Large-T antigen is of a class of oncogenes that can both immortalize primary cells and release (or transform) cultured cells from their normal growth controls, such as contact inhibition and dependence on serum growth factors[24]. Yet, *in vivo* SV40 virus will produce tumours in mice only after a long latent period; oncogenesis seems to be related to the efficacy of the immune response and the presence of large-T antigen on the cell surface as well as in the nucleus[33–35]. There is no evidence of an immune response to hyperplastic islets, nor of large-T antigen on the surface of β-cells; it remains to be established whether the frequency of solid tumour formation is associated with an escape from immune surveillance. A similar hybrid gene, composed of the 5′ flanking region of the rat elastase gene linked to the coding information for SV40 large-T antigen, produces tumours of the exocrine pancreas in transgenic mice (R. Brinster and R. Palmiter, personal communication), which further indicates that T-antigen is oncogenic in mice. Given that large-T antigen synthesis is the primary event, there are other potential secondary alterations that may be necessary to induce the development of solid β-cell tumours. These include activation or inactivation of growth factors or receptors, or the cooperation of another oncogene[36,37]. It is well established that nascent tumours cannot exceed certain size constraints without becoming vascularized; thus the induction of angiogenesis[38] is probably one (if not the only) secondary event necessary for solid tumour development. Biochemical and further histochemical comparisons of the islets before and after the predictable development of tumours may provide insight into these possibilities.

The ability to examine the pre- and postnatal development of the endocrine pancreas as well as heritable oncogenesis, using as markers the hormone gene products of these cell types and the SV40 tumour antigen, will provide a means to examine the consequences of cell-specific oncogene expression and the ontogeny of the effects reported here, as well as to address further aspects of the control of insulin-gene expression. It will be of interest to compare different recombinant insulin/oncogenes (such as *myc* and *ras*) for their effects on islet-cell biogenesis and cell–cell interaction, and on secondary events necessary for the development of β-cell tumours.

I thank David Lane, Sue Hockfield, Beth Friedman and Ed Harlow for advice on immunohistology and protein blotting; Jim Watson, Winship Herr, Terri Grodzicker, Pam Mellon and Joe Sambrook for comments on the manuscript; Liz Lacy and Frank Costantini for instruction in microinjection; Stanley Minkowitz and Bartol Matanic for several pathology examinations; David Lane and Robert Santerre for antisera; Rich Cate and Wally Gilbert for the rat insulin gene; Debbie Lukralle for animal care; Mark Lacy for technical assistance; Mike Ockler and Dave Green for artwork; Marilyn Goodwin for preparation of the manuscript; and Jim Watson and Joe Sambrook for support and encouragement. D.H. was initially a Junior Fellow of the Society of Fellows, Harvard University and is currently a Special Fellow of the Leukemia Society of America. This work was funded by the Robertson Research Fund of the Cold Spring Harbor Laboratory and by a grant from Monsanto Company.

Colour, albedo and nucleus size of Halley's comet

Dale P. Cruikshank*, W. K. Hartmann† & David J. Tholen*

Halley's comet (1982 i) is now bright enough for broadband photometry by large infrared telescopes[1–3]. We report here on photometry of the comet in the *B* (0.44 μm), *J* (0.55 μm), *V* (1.25 μm) and *K* (2.2 μm) broadband filters during a time when the coma was very weak and presumed to contribute negligibly to the broadband photometry. The *V* − *J* and *J* − *K* colours suggest that the colour of the nucleus of Halley's comet is similar to that of the D-type asteroids, which in turn suggests that the surface of the nucleus is of albedo < 0.1.

The first detection of Halley's comet in the near-infrared was made on 20 December 1984, when the comet was 5.39 AU from the Sun[1]. Our new observations at *J* and *K* were made on February 18.3 and 20.3, 1985 with the 3-metre NASA Infrared Telescope Facility (IRTF) at Mauna Kea, Hawaii, and measure reflected sunlight, not thermal emission from the comet itself. Simultaneously, we obtained *B* and *V* filter data with the 2.2-metre University of Hawaii telescope, also on Mauna Kea. All data were corrected for extinction and system response by comparison with standard stars. Table 1 gives the results of the observations, together with the comet's distances from the Earth and the Sun, and the solar phase angles. The *B* and *V* photometry was done with a 9.5-arc s diameter aperture, with sky measurements of the same field taken after the comet had moved completely away. With the IRTF we used an 8-arc s aperture and a 20-arc s amplitude oscillation of the telescope's secondary mirror to correct for the sky radiation. Both telescopes were set to follow the apparent motion of the comet across the sky. We

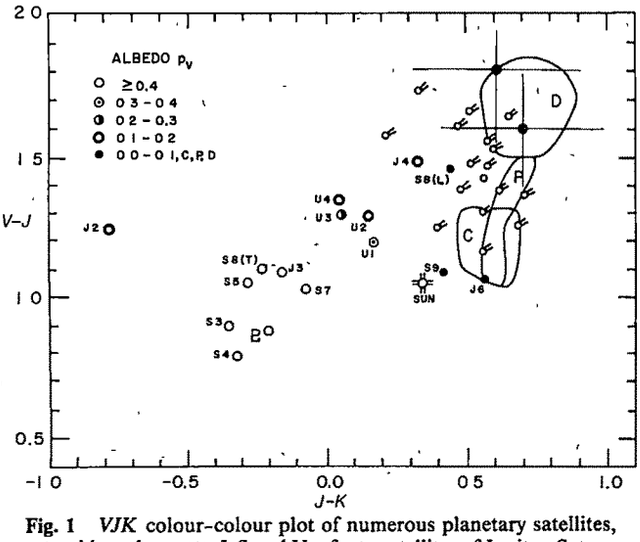

Fig. 1 *VJK* colour-colour plot of numerous planetary satellites, asteroids and comets. J, S and U refer to satellites of Jupiter, Saturn and Uranus, respectively. The fields for C, P and D-type asteroids are shown schematically, based on our data for 6 Cs, 5 Ps and 6 Ds. The two data points with error bars shown in the D field are the results for Halley's comet reported in the present work. This figure is reprinted, with modifications, from ref. 7.

could not see the comet visually through either telescope; it was located by means of a two-body ephemeris (computed by D.J.T.). The 2.2-metre telescope was then peaked on the signal through the *B* filter where the signal was strongest. The IRTF was then directed to the comet by precision offsets from field stars (observed by D.J.T.).

The question of how much light is contributed in the various filter bands by the weakly developed coma around Halley is an important factor in the interpretation of the photometry reported here. On 24 January 1985, a very weak coma was observed in 3-min unfiltered exposures with a charge-coupled device (CCD) on the 2.2-metre telescope (C. R. Chapman, D.P.C. and J. M. Pasachoff). The coma was ~5 arc s in diameter and was also very weak in long exposures (24 min) with a filter centred on the H_2O^+ emission band at 7,025 Å. We do not have a corresponding CCD image of the comet at the time of our February photometry.

The *V* filter used in this work extends from about 5,200 to 6,000 Å (20% transmission points) and misses most of the emission in the C_2 Swan band at 5,150 Å. It includes all of the weaker C_2 band at 5,550 Å. The *B* filter includes the C_3 band at 4,030 Å and C_2 at 4,700 Å. All of these bands are prominent in bright, active comets. The *J* filter includes the CN (0—0) band in very bright comets, such as West (1976 vi)[4]. A preliminary evaluation of spectrophotometric observations obtained in February by A. L. Cochran (personal communication) showed no significant emission of CN or C_2, thus suggesting that our *V* filter measurements are not seriously contaminated by coma emission bands. Similarly, the *J* filter is not expected to be contaminated because of the weakness of the CN (0—0) band. We note that any emission in the *V* filter would serve to lessen the $V-J$ colour. Thus, the $V-J$ values plotted in Fig. 1 are lower limits, and the comet was at least as 'red' as we show.

Table 1 gives the observed magnitudes and $J(1, 0)$, the *J* mag reduced to unit distance from Earth and Sun and corrected to zero phase, assuming a phase coefficient of 0.039 mag deg^{-1}, a value commonly used for asteroids in the *V* filter. We also include a nearly contemporaneous measurement of *J* and *K* from Brooke and Knacke[2]. In the present discussion, the colours $V-J$ and $J-K$ are of most interest. For February 18.3, we find $V-J=1.6\pm0.2$ and $J-K=0.7\pm0.3$. The mean of the three independent determinations of the $B-V$ colour is 0.6 ± 0.1.

The interpretation of these colours in the context of the small bodies of the outer Solar System (OSS) requires a brief discussion of previous work on this subject. In a series of recent papers[5-7], we reported photometry of OSS bodies with emphasis on the colours of ices and soils on their surfaces. On bright objects, various ices (water, methane and sulphur dioxide) and mineral components of soils have been identified by medium-resolution spectrophotometry. Broadband filter observations can be used in conjunction with the spectrophotometry of the brighter objects to establish correlations between *VJK* colours and spectral classes (related to surface compositions). These correlations are assumed to apply to the fainter bodies for which only *VJK* photometry can be obtained at an adequate signal-to-noise ratio with presently available instrumentation. Halley's comet falls into this latter class because of its faintness at the solar distance when we observed it. At much smaller solar distances, the coma could be expected to develop to the point where the nucleus itself is no longer visible and the measurements would refer instead to the material in the coma.

Among small bodies in the OSS we have found a range of *VJK* colours from relatively blue to red, with clumping at the extremes, as shown in Fig. 1. The satellites of Jupiter, Saturn and Uranus (keyed with J, S and U, respectively) are known from spectrophotometry to be dominated by water ice, with increasing ice abundance towards the lower left part of the figure. Satellite J4 (Callisto) has the weakest ice bands in its spectrum. The D, P and C-type asteroids define three fields in the $V-J$ and $J-K$ colour diagram, as indicated by the enclosed areas in the figure.

The trend in the colours shown in Fig. 1 can be interpreted if OSS bodies are composed of mixtures of ice and dark (carbonaceous?) condensates. The surfaces, then, are mixtures of bright ices and dark soil, and the ratio of the two components determines colour and albedo. The ice/soil ratios are determined in turn by geological processes on the bodies. The *VJK* colour diagram is remarkably effective for discriminating between the C and D subtypes of dark materials. The redder D-type (abundant among Trojan asteroids) is isolated in the upper right part of Fig. 1, while the more neutral C- and P-types fall in the right centre.

The C-type asteroids in the outer belt are believed to resemble carbonaceous meteorites containing up to some 20% water. They are black objects with albedos of ~0.04 and flat spectra. The D-type objects have similar low albedo but a more reddish-black colour. Gradie and Veverka[8] concluded that the D-type objects are coloured by organic material representing a lower temperature condensate than the carbonaceous material colour-

* *B* and *V* measurements at the 2.2-m telescope (by D.J.T.).
† Derived from *B* measured on this night and $B-V$ determined on February 17, 19 and 20.
‡ Average of two measurements: at 0648 UT, $B=20.28\pm0.05$; at 0842 UT, $B=20.35\pm0.06$.

ing the C-types. This would be consistent with formation of the D-type objects at a great heliocentric distance. Gradie and Veverka predicted that the D-type material ought to dominate the silicate component in the outermost Solar System and might comprise the dusty constituent in comets[8]. Our observations of several comets, some of which were active and some of which were not, confirm that comets always lie near the D, P and C-class asteroid colours, as shown in Fig. 1. No comet observed by us has a colour consistent with clean ice, and the majority of them have colours just offset from the D colours. The ices of comets are therefore coloured by dark dust similar in colour to D-class asteroid material, in excellent agreement with the Gradie-Veverka prediction[8] that comets contain D-type dust.

We note that the mean $B-V$ colour of Halley's comet is also consistent with D-type asteroids[9]. Because the comet is near to the brightening curve of an asteroid, and because of the minimal coma and emission in our wavelength regions, we may be seeing the nucleus. If so, the nucleus may have the appearance of a D-type asteroid, with a radius of about 10 km (calculated from equation 2 in ref. 13, using albedo 0.04). Alternatively, the nuclear condensation we observed may have been a swarm of particles. If those particles were macroscopic in size, colouring effects due to scattering by particles smaller than the wavelength of our observations should be minimal, and the albedos of the individual fragments would be of the order of 0.04.

Table 1, particularly the column for $J(1, 0)$, shows that the reduced brightness of the comet was changing. While this could be attributed to activity in a developing coma, rather significant variations in brightness were detected at solar distance 8 AU where no comatic activity is expected[10]. The variations in brightness have been widely considered as evidence for rotation of an irregularly shaped nucleus[11,12], although no unambiguous period has thus far been established.

The authors were visiting astronomers at the Infrared Telescope Facility, which is operated by the University of Hawaii under contract from the National Aeronautics and Space Administration. We thank Joseph Piscitelli for assistance at the telescope. This work was supported in part by NASA grant NGL 12-001-057. The Planetary Science Institute is a division of Science Applications International Corporation. This is PSI Contribution No. 207.

Note added in proof: Hughes[14] has estimated the disk and other properties of Halley's comet from a consideration of its performance during the 1910 apparition. He finds that $D^2 p_V = 5.90 \pm 0.33$ km^2, where D is the diameter and p_V is the geometric albedo at the V filter wavelength. The diameter derived by Hughes is approximately half that found by us at a similar albedo.

On the size of the galactic centre compact radio source: diameter < 20 AU

K. Y. Lo*, D. C. Backer†, R. D. Ekers‡, K. I. Kellermann‡, M. Reid§ & J. M. Moran§

The existence of a compact nonthermal radio source at the galactic centre was first suggested by Lynden-Bell and Rees[1] as the possible signature of a black hole. Such a source was detected unambiguously by Balick and Brown[2]. Very long baseline interferometry (VLBI) observations of the structure of this source, hereafter referred to as Sgr A*, have been made for several years[3,4]. In all previous experiments, the visibility amplitudes, measured over a restricted (U, V) range, could be fitted only to the simplest model of brightness distribution, that is, to a circular gaussian. We have re-observed Sgr A* at λ3.6 cm and λ1.35 cm with many baselines, using the more sensitive receivers and VLBI recording terminals now available. These observations set an upper limit of 20 AU (3×10^{14} cm) to the diameter of Sgr A* at λ1.35 cm and reveal for the first time an elongated structure at λ3.6 cm, with the position angle of the long axis almost parallel to the rotation axis of the Galaxy. Sgr A* is unique in our Galaxy, but resembles most closely the compact radio sources at the centre of external galaxies. Observations of the central 4 arc s (0.2 pc) at radio and other wavelengths are best explained by a single massive collapsed object at the galactic centre.

The λ3.6-cm observations were made on 7 May 1983, using six telescopes: Haystack 36-m; National Radio Astronomy Observatory (NRAO) 43-m; Fort Davis 26-m; Goldstone 64-m (DSS14); Owens Valley Radio Observatory (OVRO) 40-m; and Hat Creek (HCRK) 26-m. The MkIII VLBI recording terminals[5] were used with an effective recording bandwidth of 28 MHz. Observations alternated between Sgr A* and the neighbouring calibrator source NRAO530. The absolute flux-density scale was fixed by observations of NRAO530 relative to 3C286 (assumed flux density of 5.4 Jy) with DSS14.

Observations at λ1.35 cm were made on 23 June 1983, using four telescopes: Haystack 36-m, NRAO 43-m, Very Large Array (VLA) phased D-array and OVRO 40-m. The MkIII recording terminal was used with a 56-MHz bandwidth. We calibrated with the H_2O maser source in Sgr B2, ~0.7° away. At the end of each Sgr A* observation, Sgr B2 was observed for 1 min. We have adjusted the scale so that the total flux density of Sgr A* was ~1.5 Jy, a value consistent with the measurement at the VLA during the observations. The size of the gaussian model discussed below is completely independent of the flux-density scale.

At λ3.6 cm, the calibrator source NRAO530 was detected on all baselines, whereas the compact radio source in Sgr A* was detected only on the short baselines formed between the DSS14, OVRO and HCRK telescopes (for visibility coverage, see ref. 6). The visibility amplitudes of Sgr A* (Fig. 1) were fitted to two simple models, namely, circular and elliptical gaussian brightness distributions. The baseline most sensitive to the difference of the two models is DSS14–HCRK because of the relatively large rotation of the baseline. The elliptical model is preferred.

The eliptical gaussian model based on all three baselines has the following parameters: the major-axis (half-power) diameter is 15.5 ± 0.1 milliarc s (marc s), and an axial ratio of 0.55 ± 0.25, with the long axis oriented at a position angle (PA) of 98 ± 15°. From 08:30 to 10:00 UT, the closure phase of Sgr A* on the DSS14–OVRO–HCRK triangle is <5°. This suggests that the elongated source is very symmetrical, but the closure phase is measured over a very limited time.

The present λ3.6-cm results, together with our earlier work[3] spanning 8 yr, set an upper limit of 0.6 marc s yr^{-1} to any change in the observed size (corresponding to a radial expansion velocity of ~16 km s^{-1} at 10 kpc). The combined data on the transcontinental baselines to DSS14 set an upper limit of 0.011 Jy (5σ) at λ3.6 cm for any component of Sgr A* with diameter ≤1 marc s, within a 2 arc s × 2 arc s box centred on RA(1950) = 17 h 42 min 29.3 s, dec.(1950) = −28° 59′ 18.2″.

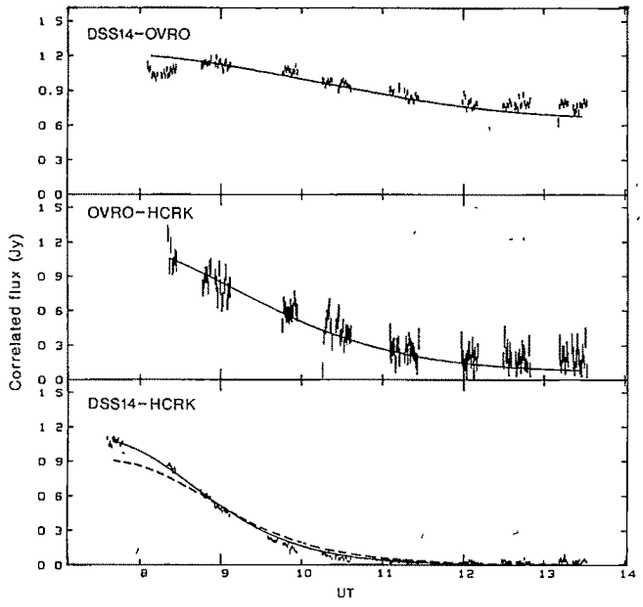

Fig. 1 Fringe amplitudes of the galactic centre compact radio source Sgr A* at λ3.6 cm (7 May 1983). The values beyond 11.00 UT on the HCRK baselines correspond to 2.5σ upper limits to the correlated flux density. The error bars represent ±1σ in the fringe fitting. The solid curves represent the best-fitting elliptical gaussian model visibility (major-axis half-power diameter = 15.5 ± 0.1 marc s, PA = 98 ± 15°, axial ratio = 0.55 ± 0.25). The dashed curve is the circular gaussian model visibility. On the other two baselines, the circular and elliptical gaussian model visibilities are essentially the same.

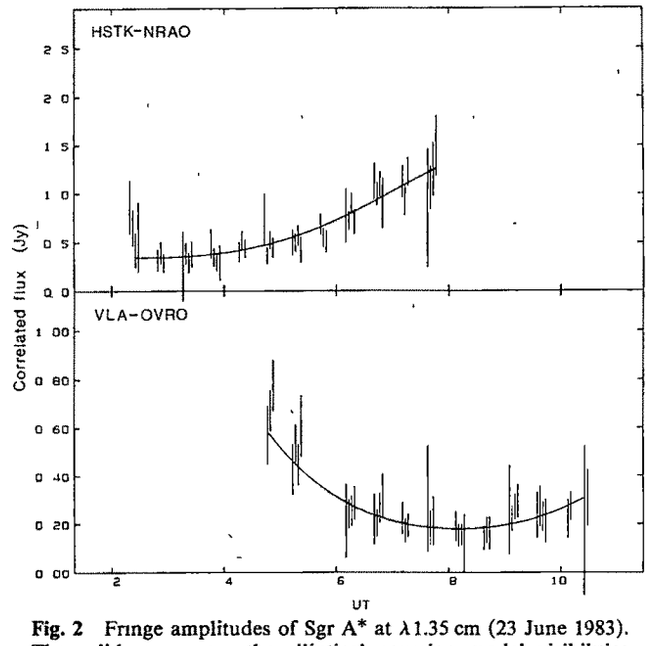

Fig. 2 Fringe amplitudes of Sgr A* at λ1.35 cm (23 June 1983). The solid curves are the elliptical gaussian model visibilities (major-axis diameter = 2.2 ± 0.2 marc s, PA = 87 ± 30°, axial ratio = 0.55 ± 0.5).

The λ1.35-cm data (Fig. 2) are well fitted by a circular gaussian model with a diameter of 2.1 ± 0.3 marc s. An elliptical gaussian fit, starting with the above model, results in a major-axis diameter of 2.2 ± 0.2 marc s, a position angle of 87 ± 30° and an axial ratio of 0.55 ± 0.5. The λ1.35-cm data are thus consistent with the elongated morphology observed at λ3.6 cm, scaled by λ^2, but do not require it.

The wavelength dependence of the angular size of Sgr A* can be derived from these data, the previously published 6-cm data[3] and 13-cm observations[7]. These are the only four wavelengths for which the angular size has been determined from visibility data with a range of variation exceeding a factor of two. All observations are mainly sensitive to the east–west brightness distribution. The sizes at λ = 13, 6, 3.6 and 1.35 cm are 203, 49.0, 15.5 and 2.1 marc s, respectively. Although these observations were obtained at different times, there is no evidence for time variations of the angular size. The exponent of the power-law dependence of the size on wavelength is 2.0 ± 0.1.

The λ^2 dependence of the source diameter could be attributed to self-absorption by internal thermal electrons[3,8], or ascribed to angular broadening of the intrinsic source size resulting from scattering by interstellar electrons[9]. The observed elongation of Sgr A* does not preclude the scattering interpretation, as a symmetrical elongated structure can be caused by scattering within a confined layer of anisotropic turbulence[10,11]. Asymmetric scattering from anisotropic turbulence in the interplanetary medium near the Sun has recently been observed (B. Rickett, personal communication). A brightness-distribution map of Sgr A* could resolve this ambiguity, because a complicated source structure would preclude interstellar scattering. Under either interpretation, the λ1.35-cm source size of 2.1 marc s (~20 AU) is an upper limit to the intrinsic source size of Sgr A*. Unless there is an abrupt change in the λ^2 dependence of the observed size for λ < 1.35 cm, the true size is ≤1.5 marc s.

If the observed size is dominated by scattering, the upper limit to the source-expansion rate observed at λ3.6 cm may not apply to the intrinsic expansion. However, even in the scattering case, the small λ1.35-cm size places an upper limit on the intrinsic source expansion of 0.26 (2.1/8) marc s yr^{-1}, or ~6 km s^{-1}, for the intrinsic source size not to exceed the scattering angle. Therefore, measurements at the two wavelengths imply an upper limit to the intrinsic source expansion velocity of <16 km s^{-1} averaged over 8 yr.

The observed parameters of Sgr A* are summarized in Table 1; its properties are similar to those of compact radio sources in galactic nuclei and quasars[12], but at a much lower luminosity. The physical conditions of the radio source implied by the observed properties have been discussed previously[8,13]. The extremely small size indicates that the scale of the underlying energy source must approach stellar dimensions. However, models of the radio source invoking stellar objects, such as a young supernova remnant, a pulsar[9], pulsar-driven wind[13] or a binary stellar radio source[8], are inconsistent with the observations[3]. Furthermore, there is no other radio source with comparable strength to Sgr A* found in the central five square degrees of the galaxy (D.C.B. and R. Sramek, unpublished results). Sgr A* is a unique radio source in the Galaxy. On the other hand, it resembles closely a weaker version of the nuclear radio source in external spiral galaxies, such as M81 (NGC3031; ref. 14) and M104 (NGC4594; ref. 15).

Problems of confinement of the radiating particles[13] and the stability of the source size would require the emission to originate in a steady wind or jet. The observed elongation of the source that is almost parallel to the rotation axis of the Galaxy (PA ~ 122°) is possible supporting evidence. Further observational constraints on the nature of the radio source must await the construction of a brightness-distribution map.

Table 1 Observed properties of the galactic centre compact radio source

Source size	<20 AU (~3×10^{14} cm)
Wavelength dependence of size	$\lambda^{2.0}$ ($\lambda \geq 1.35$ cm)
Position angle of elongation	98 ± 15° (λ = 3.6 cm)
Axial ratio	0.55 ± 0.25 (λ = 3.6 cm)
Upper limit to source expansion	<16 km s^{-1}
Flux density variability ($\Delta S/2S$)*	≤0.2 (1975–83)
Spectral index (ref. 29)	~0.25
Turnover frequency (ref. 29)	≥89 GHz
Radio luminosity	~2×10^{34} erg s^{-1}
Brightness temperature	>7×10^8 K (λ1.35 cm)

* ΔS, peak-to-peak variation; S, mean flux density; ref. 28 and J. van Gorkom, K.Y.L. and M. Claussen, unpublished results.

The central few square degrees of the Galaxy are full of interesting and energetic phenomena on many size scales[16-19], in the middle of which lies the unique Sgr A*, coincident to within 0.5 arc s of IRS16 centre. IRS16 may be the primary source of the $\sim 10^7\ L_\odot$ of infrared and ionizing radiation from the centre[20-22]. A $3\times10^6\ M_\odot$ point mass within 0.5 pc of the centre is suggested by the latest Ne II observations (E. Serabyn and J. H. Lacy, in preparation). Furthermore, a large velocity ($\pm 750\ km\ s^{-1}$) outflow[23,24] and, possibly, a compact source of positronium[25] are also identified with the central 0.2 pc ($\sim 5\times 10^{17}$ cm, or ≤ 4 arc s).

Although the luminosity and ionization over the 10^{20}-cm scale of the galactic centre may be explained by a recent burst of star formation[26], the activities within the central 5×10^{17} cm require an alternative source of energy, such as a massive collapsed object in a quiescent state of low-level accretion[27]. The unique compact radio source and the other phenomena at the centre would be natural consequences of the presence of such an object.

We thank M. Cohen for encouragement and for reviewing the paper critically and Alan Rogers and Paul Ste Marie for help in the data reduction. Middle atmospheric NO and NO_2 observed by the Spacelab grille spectrometer

J. Laurent*, M.-P. Lemaitre*, J. Besson*, A. Girard*, C. Lippens†, C. Muller†, J. Vercheval† & M. Ackerman†

* Office National d'Études et de Recherches Aérospatiales, F-92322 Châtillon, France
† Belgium Institute for Space Aeronomy, B-1180 Brussels, Belgium

Almost 20 years after Nicolet[1] suggested the presence of nitric oxide in the upper atmosphere as a source of D-region ionization by solar Lyman α-radiation, this trace species was first observed[2] by the resonance fluorescence method; almost 10 years later, its vertical distribution was observed in the stratosphere by means of balloon-borne infrared absorption spectrometry[3]. Since then much emphasis has been placed on odd nitrogen compounds in the stratosphere, partly because of their role in controlling the ozone abundance. Many measurements have been made of NO, NO_2, HNO_3 and NO_3 in the stratosphere with inferences on the N_2O_5 abundance. Meanwhile, several determinations of NO in the mesosphere and in the lower thermosphere[4-10] have used resonance fluorescence and mass spectrometry[11]. We report here the first observation of NO from the low thermosphere down to the low stratosphere by instrumentation similar to that used previously on board balloon gondolas, but on this occasion the observation platform was Spacelab I, which gave access to higher altitudes. As before[12], NO and NO_2 were observed simultaneously.

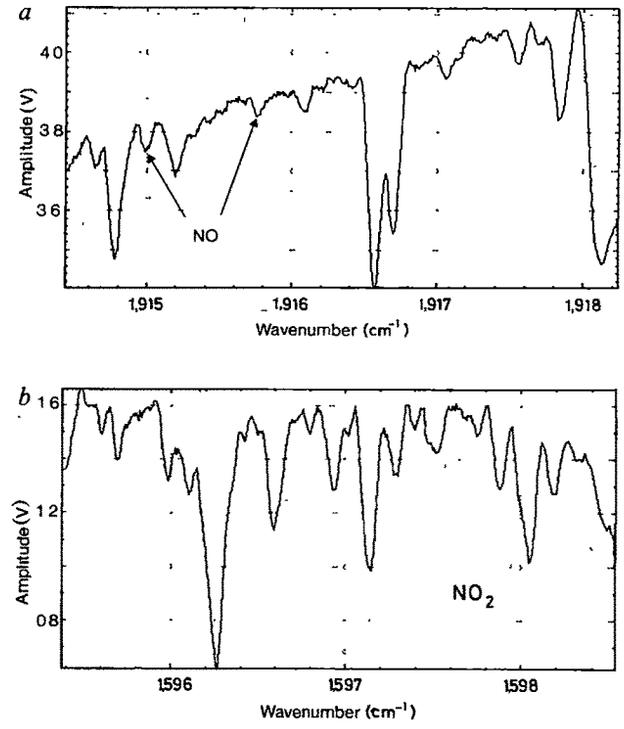

Fig. 1 *a*, Solar spectrum recorded at sunlight-tangent altitude equal to 86 km. Two NO absorption lines are indicated; all the other spectra lines are attributable to solar absorption features. *b*, NO_2 absorption spectrum recorded at sunlight-tangent altitude equal to 26 km. In this spectral region, the solar spectrum is a continuum. Most of the spectral features are attributable to nitrogen dioxide. In *a* and *b*, amplitudes are in arbitrary units and the origin of the scale is the level of total absorption for the solar radiation.

The infrared grille spectrometer on board the space shuttle during the first Spacelab mission has been described elsewhere[13]. During this mission, one Earth-limb solar occultation run was devoted to the observation of NO and NO_2 in the respective wavenumber ranges, 1,914.5-1,918 cm^{-1} and 1,595-1,598.5 cm^{-1}. The corresponding wavelengths were selected in the sixth and fifth orders of the grating by two interference filters, one for each of the two liquid nitrogen temperature-cooled detectors.

This observation took place over the southern Pacific Ocean on 1 December 1983, at sunrise after the very short nights of the high southern latitudes in their late spring. For the 20- and 100-km tangent-altitude locations, the solar depression angles did not exceed 0.3° and 1.4° respectively, during the course of the day. The geographical coordinates of the tangent points of the solar rays in the atmosphere were respectively 68° S, 129° W and 67° S, 118° W. Thus, the observations took place in almost full daylight; almost all the odd nitrogen was in the form of NO in the mesosphere and NO, NO_2 and HNO_3 in the stratosphere, according to our present knowledge of atmospheric photochemistry. NO and NO_2 spectra (examples are shown in Fig. 1*a*, *b*) were recorded every 2 s and the measured equivalent

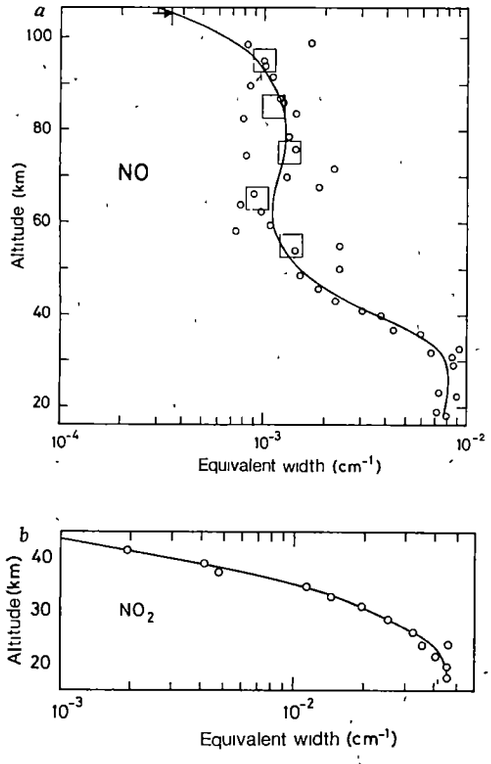

Fig. 2 Equivalent widths versus grazing-sunlight altitude for *a*, the NO absorption doublet at 1,914.99 cm^{-1} (the squares represent five kilometres averages) and *b*, the NO_2 multiplet centre at 1,597.15 cm^{-1}.

widths versus tangent heights in the atmosphere are shown in Fig. 2*a*, *b*.

The data, represented by the smooth curves in Fig. 2*a*, *b*, were invented using the molecular-line parameters of Rothman *et al.*[14] in the 'onion peeling' inversion method, which leads to the vertical distributions of NO and NO_2 shown in Fig. 3. Above 98 km altitude, the scanned wavelength intervals broadened to observe broader band solar spectra. The 1,914.99-cm^{-1} NO line region was observed again at 105 km tangent altitude where the NO signal was too weak to be detected. From 55–75 km of

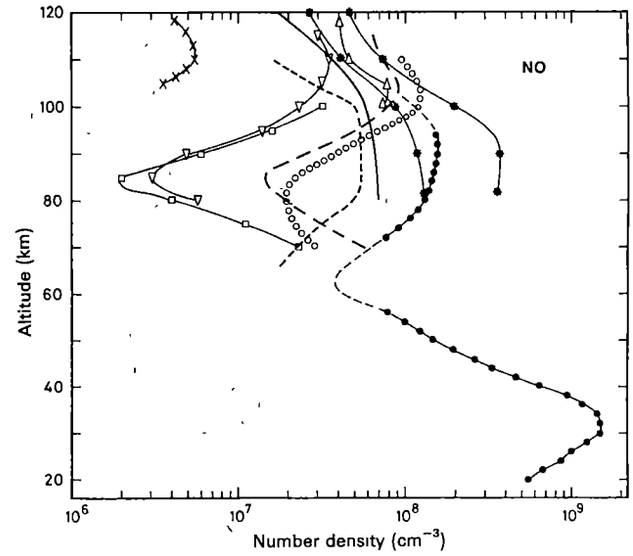

Fig. 4 Nitric oxide number densities presented in this paper are compared with the results of other authors. Barth[2] (——); Meira[4] (—·—·—); Tisone[5] (– – – –); Witt *et al.*[6] (○); Backer *et al.*[8] (□); Thomatsu-Iwagami[7] (▽); Thomas[9] (×), Trinks *et al*[11] (△); this work (—·—·—); Massie[10] (*—*, sunrise).

altitude a dashed line represents inverted NO number densities, so low that the slant absorption must be attributed to NO at higher altitudes. Hence, at this altitude the NO abundances can only be given tentatively and probably represent an upper limit.

The stratospheric portion of the observation is characterized by a high signal-to-noise ratio for the absorption lines. Hence, the uncertainty on the volume concentrations is small and the values, which will be discussed elsewhere, are in the range of previous observations. Our results are compared in Fig. 4 with other observations in the mesosphere and in the low thermosphere. Although our results are in rather good agreement with other observations at the highest altitudes, the differences become very large at 85 km, particularly with the vertical profiles exhibiting a minimum volume concentration at that altitude. The shape of the vertical profile compares as well as possible with the results of Barth[2] and Tisone[5]. The only other absorption measurements to compare with our data are those of Massie[10], based on OSO-8 observations of the (1.0) δ band at 182.94 nm, which are in good agreement.

Slight modifications of our new data may be necessary if further refinement were to alter significantly the orbit parameters of the shuttle during the first Spacelab mission. More observations will be possible when the instrument is flown in a mission dedicated to atmospheric studies. When this happens we should gain understanding of the the distribution of NO in the mesosphere, which shows a disagreement between the NO abundances derived from different observation methods. This has important consequences for modelling neutral and charged-particle abundances in the upper-middle atmosphere and ionospheric D and E regions.

Measurement of surface currents in Liverpool Bay by high-frequency radar

D. Prandle & D. K. Ryder

Institute of Oceanographic Sciences, Bidston Observatory, Birkenhead, Merseyside L43 7RA, UK

The backscattering of high-frequency radar echoes from the sea surface can yield useful information about ocean waves and surface currents[1–3]. The Rutherford Appelton Laboratory Ocean Surface Current Radar (OSCR) system is based on the CODAR system[4] but differs significantly in that it uses a beam-forming receive antenna to determine the direction of the backscattered signals instead of using the CODAR direction finding system. OSCR derives a radial component of surface velocity by measuring the shift in recorded spectra associated with advancing and receding waves. In this survey of surface currents in Liverpool Bay, using only OSCR, measurements were made first for 7 days from the Lancashire coast followed, 1 month later, by similar measurements from the Wirral coast. These were combined to compute current ellipses for the predominant M_2 tidal constituent. Spatial distributions of the ellipse parameters agree well with values obtained from a numerical model and from moored current meters. This new observational technique should provide data on the fine structure of near-shore surface currents for use in studies of sediment transport and pollutant dispersal.

The handicap of having only one OSCR unit was overcome by deploying it in an area where tidal currents predominate. Tidal measurements from two separate deployments could be combined to produce a stereoscopic image. Liverpool Bay was selected as a suitable site because, in addition to the convenient shoreline geometry (Fig. 1), the region is characterized by strong tidal currents flowing over complex bottom topography, thus producing horizontal structure on a scale commensurate with the resolution of OSCR. Despite the influence of major estuaries, the tidal forcing is sufficient to overcome vertical stratification. Moreover, harmonic analysis of tidal elevations in this region indicates the predominance of three major constituents, namely M_2, S_2 and N_2. This allows a reasonable resolution of the primary M_2 constituent from a data set as short as 25 h.

The computing system installed in OSCR at the time of this experiment limited data acquisition to measurements along just four beams per hour. Hence, the net duration of data recorded for each beam was restricted to between 1 and 4 days. Measurements were made over 14 beams each 6° wide; resolution along each beam consisted of 20 bins each 1.2 km long. Previous preliminary trial results[5] have indicated that, using an integration period of about 10 min, current measurements accurate to 1 cm s^{-1} can be obtained.

A simplified tidal analysis was performed by correlating (1) the time series $Z(t)$ for tidal elevations at Liverpool (predicted from harmonic constants) with (2) the time series $U(t)$ for the radial current component in a specific bin. A phase lag δt was introduced between these time series and the error $\varepsilon(\delta t)$ determined for the relationship

$$\varepsilon(\delta t) = \sum_{t=1}^{N} [(U(t) - \bar{U}) - \alpha(Z(t+\delta t) - \bar{Z})] \qquad (1)$$

where N is the total number of relevant observations, $\bar{U}$ and $\bar{Z}$ are means of the respective time series and the coefficient α was calculated by the method of least squares to minimize ε.

In this manner, the value for δt_{min} (within the range −12 h to +12 h) corresponding to the smallest overall value of ε was determined. The value δt_{min} was then assumed to represent the phase lag of current relative to elevation for the predominant M_2 constituent. Similarly the amplitude of the M_2 constituent of tidal current was assumed to be given by the product of α (corresponding to δt_{min}) and the M_2 amplitude for tidal elevation. The accuracy of this analysis was aided by the quiescent meteorological conditions with winds <10 knots for 80% of the time.

At each intersection point of the two beam sets shown in Fig. 1, the elliptical pattern of surface tidal currents for the M_2 constituent was calculated by linear interpolation of the respective current components in the nearest two bins. The component parts of Fig. 2 indicate the spatial distribution of the four parameters concerned: (1) amplitude of the major axis of the ellipse; (2) direction of the major axis; (3) phase or timing of the occurrence of maximum current relative to the lunar transit; and (4) ellipiticity, with positive values indicating anticlockwise rotation. Figure 2 also indicates comparable values

Table 1 M_2 tidal ellipse properties at 53° 28.3'N, 3° 15.4'W

	Amplitude (major axis) (cm s^{-1})	Direction* (deg)	Phase (deg)	Eccentricity (+ve anti-clockwise)
Numerical model	58	350	243	−0.02
Current meters (1)	54	351	237	−0.02
(2)	50	356	231	−0.04
High-frequency radar (surface)	61	342	232	+0.03
High-frequency radar corrected to mid-depth value	55	344	229	+0.08

* Measured anticlockwise from due east.

obtained from a numerical model based on a 1-km rectangular grid. In the model, the tides are specified at both the northern and southern limits of the Irish Sea and comparison between tide gauge recordings and model computations for M_2 elevations in Liverpool Bay indicates agreement to within 2% in amplitude and 7° in phase. Figure 2*a* is reproduced to a larger scale to illustrate the actual values of current amplitude obtained from the radar observations. The spatial coherence indicated by these values suggests that the precision of the radar measurements is of the order of 1 cm s^{-1}, thus substantiating theoretical estimates. Moreover, the agreement between spatial patterns from the radar measurements and the model establishes the accuracy of this instrument.

The surface amplitudes indicated by the radar are larger than the depth-mean values calculated in the model. This tendency is predicted from theoretical analysis of current structure[6,7]. Thus, for a position in the centre of the survey region, Table 1 indicates M_2 ellipse properties from (1) the numerical model, (2) two current meters, (3) the high-frequency radar surface measurements and (4) the high-frequency radar measurements corrected to reflect conditions at mid-depth. (The current meter deployments formed part of the OSCR evaluation experiment.) These latter corrections were carried out by resolving the ellipse into clockwise and anticlockwise components and assuming the current structure shown in Fig. 5 of ref. 6. Relative to surface values, the current ellipse at mid-depth exhibits a smaller amplitude, phase advance, increase in anticlockwise eccentricity and the direction may veer in either sense[7].

Table 1 also indicates that for the two current meters, located just 500 m apart, amplitude may vary by 10% and both phase and direction by 5°. Thus, allowing for the inherent spatial variability in current ellipse properties, both vertically and horizontally, the small discrepancies shown in Table 1 between the ellipse properties measured by the high-frequency radar and those obtained elsewhere appear entirely explicable. Likewise, the agreement between the high-frequency radar measurements and the numerical model shown in Fig. 2*b*, *c* and *d* for direction, phase and eccentricity respectively is within the limits of expected variability.

The residual circulation in Liverpool Bay is influenced by tides, winds and density gradients and hence may be highly variable in time. To construct a residual flow pattern from the present radar data involving velocity components measured on separate days up to 5 weeks apart must be of questionable validity. However, an examination of the residual current data was made both as an illustrative example of the potential use of dual OSCR systems and to indicate the order of magnitude of surface residuals even if the spatial distribution proved incoherent. Residual currents R for each bin were obtained from the expression

$$R = \bar{U} - \alpha\bar{Z} \qquad (2)$$

where $\bar{U}$ and $\bar{Z}$ represent the means calculated in equation (1) and the value of α corresponds to $\delta t_{\min}$. Then for each intersection point of the two beam sets, a residual current vector was calculated using linear interpolation between the respective

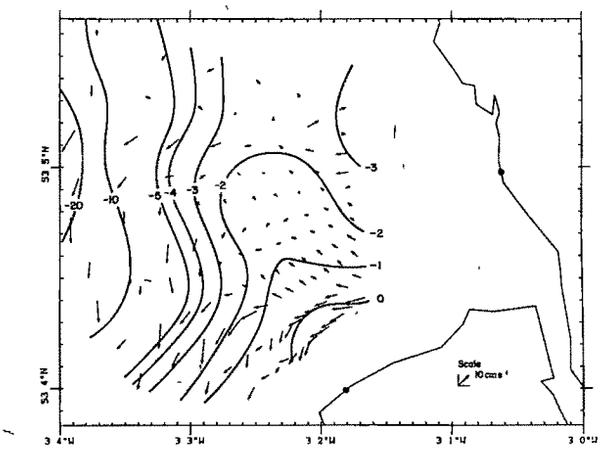

Fig. 3 Residual circulation measured by high-frequency radar. Streamlines are in units of 10^3 m^3 s^{-1}.

residual current components in the nearest two bins. Figure 3 shows these observed residual current vectors together with superimposed streamlines. The streamlines are based on the assumption that the surface residuals persist uniformly throughout the water column. The streamlines were constructed using the intersection of beam 9 from Hoylake and beam 5 from Crosby as a zero datum. The spacing of the streamlines was then determined along each beam from Hoylake by calculating the total flow orthogonal to each beam relative to a datum along beam 5 from Crosby. These datum values for beam 5 (Crosby) were initially determined in similar fashion by calculating flow orthogonal to the beam.

The results shown in Fig. 3 suggest residual currents at the surface of up to 19 cm s^{-1} with a mean value of about 5 cm s^{-1}. The maximum currents occur in the deeper water on the western boundary of the survey region. In this region, a strong southerly flow is indicated involving a flow of 20×10^3 m^3 s^{-1}, this latter circulation may be compared with a freshwater discharge of the Mersey of $\sim10^2$ m^3 s^{-1} and a net flow through the Irish Sea of about 60×10^3 m^3 s^{-1}.

Over the shallower regions in the eastern section, the residuals are much smaller and form an anticlockwise gyre. In the south-western section, a pronounced westerly circulation is suggested. Residuals measured by the moored current meters averaged over the period 1 April to 17 May 1984 were 5.6 cm s^{-1} towards the south-southwest 4.3 cm s^{-1} eastwards. The latter may reflect the proximity of this mooring to the knoll shown in Fig. 1 while the former value reflects assymetry in the direction of flood and ebb currents of some 10°. The magnitude of these currents is of the same order as the surface residuals shown in this region in Fig. 1, while the variation in their directions illustrates the limitations of conventional instruments for measuring residuals in regions of this kind.

Despite extensive efforts to measure the residual circulation in Liverpool Bay[8] there is no clear pattern against which to evaluate Fig. 3.

One residual flow component, seemingly overlooked in these earlier studies, is the Stokes drift arising from variation in total water depth over the tidal cycle. For the predominant M_2 constituent, a tidal elevation $\hat{Z}\cos\omega t$ combined with a tidal current $\hat{U}\cos(\omega t - g)$ produces a residual flow $\frac{1}{2}\hat{U}\hat{Z}\cos g$. Using the distribution of M_2 currents shown in Fig. 2 with the $\hat{Z}$ value of (295 cm, 318°) we calculate a net flow over the survey region due to Stokes drift of 10×10^3 m^3 s^{-1} directed southeastwards towards the Mersey (the direction corresponds to the net propagation of tidal energy). The velocities associated with this flow range from 2 cm s^{-1} in the deepest water to over 10 cm s^{-1} in the shallower southeasterly region. This Stokes transport must be counterbalanced by an Eulerian residual current component. The latter requirement may partially explain the strong westerly flow observed in the southern region of the radar data. However,

both observations and theory suggest that residual circulation in areas of the kind considered differ significantly between surface and bed and such considerations are beyond the scope of the present paper.

The residual circulation thus forms a coherent pattern with current magnitudes comparable with theoretically derived residual flow components. Most excitingly, high-frequency radar offers the possibility of measuring the residual circulations (at the surface) in such regions where conventional instruments have proven ineffective.

This initial evaluation of OSCR has confirmed the accuracy of the instrument and provided unique data on both tidal and residual circulation in Liverpool Bay. Further, more rigorous, determination of the accuracy of OSCR measurements is hindered by the absence of comparable independent measurements, the present results suggest a significant advance over the levels of accuracy cited in earlier high-frequency radar measurement[9-11].

Using the two OSCR units now available, similar surveys in other coastal areas can, in as little as 7 days, produce current data which may well supplant conventional data sets obtained over many years of observations. For the first time, the fine detail of spatial structure of surface currents can be measured. This should improve our theoretical understanding of the circulation within bays, around headlands, sand banks and so on, and thus be of direct benefit in studies of sediment transport, dispersal of pollutants or ship navigation.

The OSCR system was developed at the Rutherford–Appleton Laboratory under the direction of J. W. King; other members of the development group, F. D. G. Bennett, D. Eccles and K. Slater, participated directly in the Liverpool Bay experiment. Current meter observations were analysed by J. Howarth (IOS Bidston). We thank other staff from Bidston who participated in the measurement programme. D.K.R. is in receipt of a postgraduate studentship from the NERC.

Lake Untersee, a first isotope study of the largest freshwater lake in the interior of East Antarctica

W.-D. Hermichen, P. Kowski & U. Wand

Akademie der Wissenschaften der DDR, Zentralinstitut für Isotopen- und Strahlenforschung (ZFI), Permoserstrasse 15, DDR—7050 Leipzig, GDR

Perennially ice-covered lakes partially bounded by glacier ice are common in some Antarctic coastal regions[1] but very rare inside the continent. Here we describe hydrological studies on the largest freshwater lake of interior Antarctica, Lake Untersee (71°20′ S/13°30′ E, surface area 10 km², maximum depth >79 m)[2], showing that the lake arose from a melt-water pond during climatic optimum periods in the Holocene. At present, the studied water body is thermally, hydrogeochemically and isotopically homogeneous because of thermal convection during the austral summer. Lake Untersee is fed throughout the year by underwater melting of the adjoining glacier ice. Isotope data suggest a permanent ice cover during its existence. The drainless lake is constantly losing water through sublimation on the surface of the more than 2.5-m-thick ice cover. The salt content suggests that the present water body is the remainder of an amount of melt water at least 50 times as great.

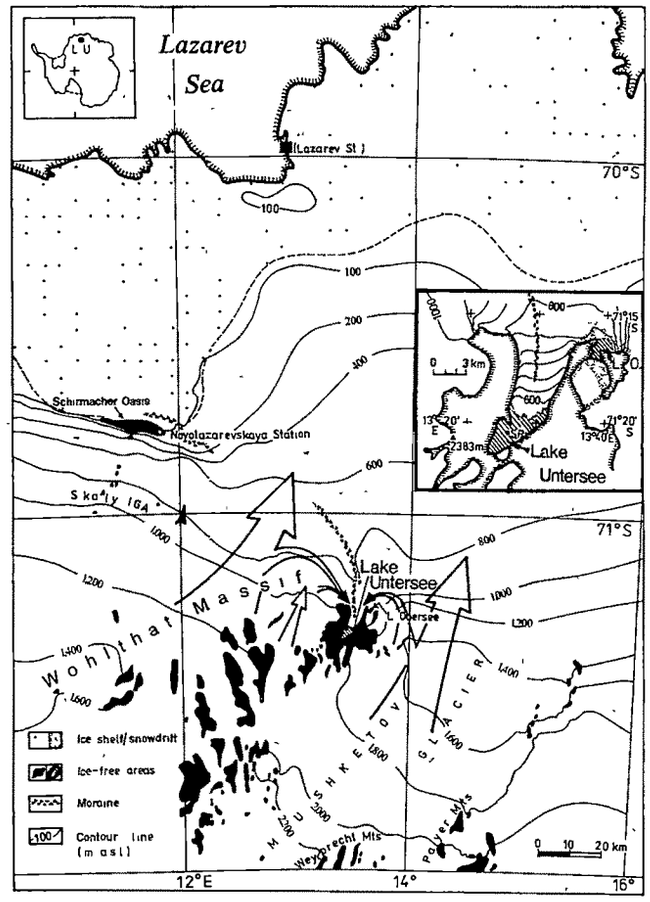

Fig. 1 Sketch map of the working area with locations mentioned in the text The arrows show the main glacier flows feeding Lake Untersee. L.U., Lake Untersee; L.O., Lake Obersee; S.P., sampling point.

On the northeastern margin of the mountains in central Dronning Maud Land, pilots of the German Antarctic Expedition in 1939 discovered two large dark ice planes under which liquid water was presumed to be present—Lake Untersee and Lake Obersee[3] (Fig. 1). Then, in 1969, a Soviet group explored Lake Untersee and proved the existence of a large water body under a 2.5-m-thick ice cover[2].

In March 1982 our group first implemented a hydrological sampling programme with the following results: (1) At the end of the summer, the water body sampled at depths of 5, 10, . . . , 40, 44 m was homogeneous down to the bottom (44 m), with respect to temperature ($T_{water} = (+0.45 \pm 0.05)$ °C), isotope composition ($\delta^2H_{water} = (-255 \pm 5)$ ‰, $\delta^{18}O_{water} = (-35.0 \pm 0.5)$ ‰) and salt content (sum of ions) ($M_{water} = (330 \pm 10)$ mg l^{-1}). Probably this remarkable homogeneity (within analytical error) results from convection, induced by the greenhouse effect of the ice cover, as known from lakes of the Schirmacher Oasis[4]. (2) The ice cover (interval 0–1.3 m) is characterized by $\overline{\delta^2H}_{ice} = (-250 \pm 5)$‰ and $\overline{\delta^{18}O}_{ice} = (-34.0 \pm 0.5)$ ‰. (The techniques of sample preparation and isotope analysis are described by Mühle *et al.*[5]. Isotope data refer to Standard Mean Ocean Water (SMOW).) (3) The tritium content of the water is below the detection limit, that is, <0.5 tritium units (TU). For comparison, large lakes of the Schirmacher Oasis, fed with melt water from old ice as well as from recent snow patches, have tritium contents of 6–8 TU (ref. 6). (4) Lake water is of sodium sulphate type with an extremely low magnesium content (Table 1, Fig. 2). (5) There are signs of primary production in the lake. As already observed[2] the bottom

is at least partially covered with an organic layer a few millimetres thick.

No continuous record of meteorological data is available, but the recent climate of the Lake Untersee region may be compared with that of the South Victoria Land dry valleys[7]: mean annual temperature of ~−20 °C and high summer aridity producing an annual sublimation rate of >200 mm of ice. In March 1982 no appreciable thawing was observed near the lake. The great difference in altitude between the lake surface (620 m above sea level (a.s.l.)) and that of the glaciers south of Lake Untersee (1,500–2,000 m a.s.l.) gives rise to strong catabatic winds.

Under recent climatic conditions the formation of such a large water body cannot be expected. Therefore, and because of the impossibility of increased endogenous heat flux, the origin of Lake Untersee must be sought in Holocene climatic optimum periods. The elucidation of the palaeoclimatic conditions of this area is the aim of investigations on organic deposits (fossilized stomach oils of petrels)[8] and ice-cores[9].

Relics of strandlines of boulders above Lake Untersee[3] indicate a former higher level of the lake and probably represent a pause in icesheet retreat (compare ref. 1). The salt content of the lake water is high compared with that of Antarctic snow and ice from locations at similar distances from the coast or similar altitudes (see Table 1)[10–19]. Marine aerosols (mainly Na^+ and Cl^-) and chemical weathering of rocks (mainly Ca^{2+} and SO_4^{2-}) are the principal sources of salts. Presumably, the local weathering solutions have a high Ca/Mg ratio because of widely distributed anorthosites (CaO/MgO > 50) in the Lake Untersee area.

For water-balance studies, chloride, which enters the lake exclusively as deposited marine aerosol via melting glacier ice, seems to be the most suitable indicator. A comparison of the Cl^- concentration of lake water (43.4 mg l^{-1}) and interior Antarctic precipitations (0.05–1 mg l^{-1}; see Table 1 and refs 10, 12, 13, 15, 19) shows the present-day water body to be the remainder of an at least 50 times larger quantity of melt water.

The isotope data indicate that Lake Untersee has been supplied mainly by underwater melting of old glacier ice in recent times. The hydrogeochemical characteristics of this inflow are determined by the precipitation chemistry of two nourishing areas (see Fig. 1): (1) the area between Richthofen, Weyprecht and Payer Mountains with a surface level of 1,400–2,000 m a.s.l. and deuterium contents of precipitations ranging between about −220 and −300‰ (ref. 20) and (2) the firn basin glacier between the Skaly IGA nunataks and the Wohlthat Massif with δ^2H ~ −200‰ (ref. 9).

If more than 200 mm are removed annually from the ice cover of the lake by sublimation, a corresponding regeneration of the floating ice cover may occur through freezing of water onto its underside during the low insolation season. However, the observed isotope differences $\delta_{ice} - \delta_{water}$ are lower than expected for a thermodynamically-equilibrated ice/water system[21] by ~15‰ (δ^2H) and ~1‰ ($\delta^{18}O$); the same tendency was observed in some lakes of the Schirmacher Oasis[4]. In both cases the ice formation seems to be diffusion controlled: concentration of the heavy isotopes in the forming ice produces a depletion in ^2H and ^{18}O in the adjacent water. If the rate of downward growth of ice is high enough, say 0.1 cm h^{-1}, diffusion, being the only active mixing process within the stably stratified water system (diffusion coefficient $D_{water}(0\,°C) = 1 \times 10^{-5}$ cm^2 s^{-1})[22], is unable to rehomogenize the liquid phase. Thus, the deeper freezing ice equilibrates thermodynamically not with the bulk water of the

Concentrations (mg l^{-1}) of cations were determined using an atomic absorption spectrometer; those of anions, by standard techniques of water analysis[27].

* Snow presumably altered by sublimation causing unusually high salt contents.

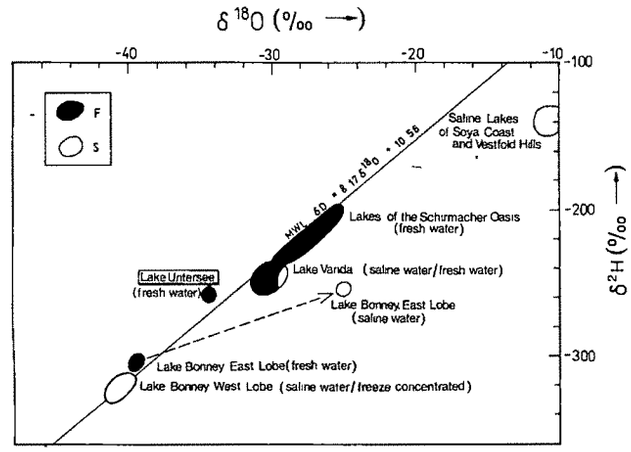

Fig. 3 Position of Lake Untersee water in the $\delta^2H/\delta^{18}O$ diagram (values versus SMOW). For comparison, data[23] of other Antarctic lakes with different evolutions are also shown. Freshwater lakes (type F) are slightly shifted isotopically to the left of the Meteoric Water Line (MWL)[21] by freeze-concentration. Saline lakes (type S) are, as a rule, isotopically shifted well to the right by dominating evaporation-concentration.

lake but with isotopically somewhat lighter water of the boundary layer. Because the sublimation of the ice cover takes place layer by layer without any isotope separation, the heavy-isotope content of the remaining liquid water decreases as the amount of water decreases[21] and it remains at slightly lowered values if input and sublimation are equilibrated[23]. In both cases, an increase in salt concentration is noted.

Lake Untersee has been predominantly or permanently covered with ice throughout its evolution. This is demonstrated by the position of its water isotope data in the $\delta^2H/\delta^{18}O$ diagram (Fig. 3), slightly shifted to the left from the global Meteoric Water Line (MWL)[21] by the isotope fractionation in the water/ice transition. The permanence of an ice cover is also supported by the occurrence of supra-glacial till boulders resting on the ice cover (compare ref. 1). The dominance of evaporation at an ice-free surface would have produced a shift to the right side of the MWL as observed in most of the Antarctic saline lakes[23].

A comparison of the strandline of the Lake Untersee on the basis of air photographs taken in 1939, 1961 and 1982 does not show any relevant change in the shape of the lake. Obviously, its mass balance in this period was approximately equalized.

More extensive work is in progress on the Lake Untersee environment as well as its Holocene evolution.

We thank the leaders and the helicopter crews of the 26th and 27th Soviet Antarctic Expeditions, M. Grelle for assistance in sampling, Drs M. Partisch and R. Zierath for hydrogeochemical analyses, Dr W. Kurze for tritium analyses and Mrs E. Kirschner for mass spectrometric measurements. This work was supported by the Central Institute for Physics of the Earth, Academy of Sciences of the GDR, Potsdam.

A new method for monitoring temporal trends in the acidity of fresh waters

Andrew L. Herczeg, Wallace S. Broecker, Robert F. Anderson & Sherry L. Schiff

Lamont-Doherty Geological Observatory and Department of Geological Sciences, Columbia University, Palisades, New York 10964, USA

David W. Schindler

Freshwater Institute, 501 University Crescent, Winnipeg, Manitoba, Canada R3T 2N6

Acid precipitation and the consequent increased acidity of fresh waters are subjects of widespread concern. Several organizations in the United States, Canada and Europe have established extensive monitoring programmes in an attempt to determine the relationship between the acidity of preciptation and the change in acidity of fresh waters. We contend here that the present strategies for monitoring temporal trends in the acidity of fresh waters will not yield results sensitive enough to detect trends in acidity even on a 10-year timescale. We propose here an alternative scheme based on calculations using precise measurements of dissolved inorganic carbon (DIC) and partial pressure of CO_2 (P_{CO_2}). This scheme eliminates biases inherent in *p*H electrode determinations and minimizes the perturbations in acidity caused by changes in the P_{CO_2} of lake waters associated with biological cycles.

A method that accurately and precisely yields hydrogen-ion activity is needed for the following reasons: (1) Aquatic biota are sensitive to hydrogen-ion activity. Most laboratory bioassay experiments refer to changes in, for example, quantity, distribution and viability of a given species as a function of *p*H. (2) Trace metal mobilization is one of the major effects of lake acidification. Hydrogen-ion activity is an essential parameter in metal speciation calculations. (3) Total alkalinity measurements cannot reliably substitute for measurements of hydrogen-ion activity. The presence of titratable organic anions leads to an overestimate of bicarbonate ion from acid titration data and hence to an underestimate of hydrogen-ion activity at any given P_{CO_2}. (4) The predicted response of a lake to acidification for a given *p*H of rain is complicated by many unknown factors such as dry fallout, soil and sediment neutralization and HNO_3 sequestering. Policies to set anthropogenic emissions of nitrogen and sulphur oxides must be based on sound predictive models derived from accurate empirical data.

The difficulties associated with measurement of *p*H using the standard glass/calomel- or combination-electrode systems have been well documented. In dilute natural waters, electrode determinations are very sensitive to sampling and handling artefacts and to liquid junction potential problems[1-6]. The use of a flow-cell electrode system[5] has to some extent remedied the last problem, although the technique has not yet received widespread application. More serious are interactions of dissolved organic carbon (DOC) and/or suspended matter with the electrodes, which cause systematic errors of up to 0.5 *p*H units[2-4].

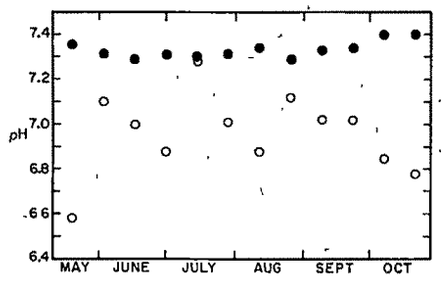

Fig. 1 Comparison of pH measured by electrodes (⊙) with pH calculated from DIC and P_{CO_2} data using equation (2) (●) for ELA lake 239 during the summer of 1982. DIC can be determined by acidifying a small volume of water to pH < 4 and then stripping the CO_2 with helium gas. The gas phase is analysed for CO_2 on a gas chromatograph or infrared analyser to a precision of better than 1%[11]. P_{CO_2} is determined by equilibrating an aliquot of water with a small volume of air and then an aliquot of the air is returned to the laboratory for GC or infrared analysis. Replicate equilibrations agree to within 2%. Equilibrations should be performed in the field because of the extreme sensitivity of the P_{CO_2} to biological processes. The hydrogen-ion content can thus be calculated with a precision of ±4% at pH 7 and ±10% at pH 5.6, which is substantially better than can be obtained by electrode measurements (±20%). The analytical precision of the pH electrode is a moot point because of the systematic errors of up to 0.5 pH units (a factor of three in H^+ activity) in the pH range 5.6–7. The measurements of DIC and P_{CO_2} are no more difficult or expensive than quality pH determination.

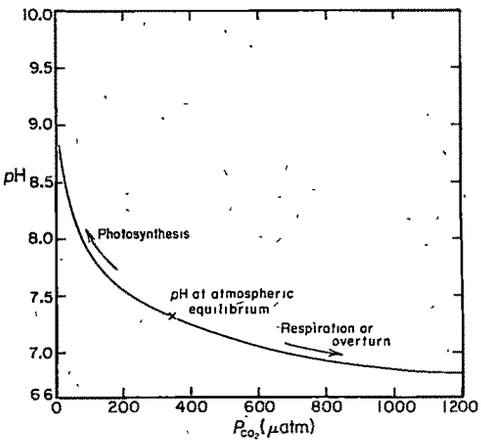

Fig. 2 Calculated dependence of pH on P_{CO_2} for lake 239 surface water. ($[HCO_3^-] = 115$ μmol l^{-1} at 20 °C.) The range corresponds to that which may be caused by algal blooms or overturn events. An upper P_{CO_2} limit of ~1,000 μatm can be achieved for surface water during fall overturn when hypolimnetic water (P_{CO_2} = 3,400 μatm; A.H., unpublished data) is brought to the surface at a faster rate than gas exchange can remove it to the atmosphere. Although we did not observe a P_{CO_2} depression in lake 239 during the summer, the response of eutrophied lakes to phytoplankton blooms[7–9] suggests that the P_{CO_2} of those lakes must be well below 10 μatm.

An intercomparison among 17 laboratories using standard electrode techniques was conducted, in which each was given an aliquot of a sample known to have a pH of 6.18 (ref. 6). They reported a mean value of 5.54 with a standard deviation of 0.74 pH units. At pH values below the accuracy and agreement were significantly better and it may be that the biases that plague electrode measurements become smaller as the hydrogen-ion activity increases.

As well as the abovementioned analytical problems, pH is sensitive to changes in P_{CO_2} (ref. 7). Photosynthesis, respiration and entrainment of hypolimnetic water, by temporarily raising or lowering P_{CO_2}, create a perturbation of the longer-term pH trend. For example, lakes that normally have a pH ≈ 7 when at equilibrium with atmospheric P_{CO_2} may have their pH driven as high as 10 during phytoplankton blooms because of the photosynthetic consumption of CO_2 (refs. 8–10). Although equilibrating water samples with standard atmospheric P_{CO_2} (340 μatm) potentially provides a means of circumventing this difficulty, this approach is subject to the electrode errors described above.

Highly accurate and reproducible hydrogen-ion concentrations can be calculated from measurements of DIC and P_{CO_2} (ref. 4) from the equilibrium relationship

$$pH = -\log \frac{[H_2CO_3^*]K_1}{([DIC]-[H_2CO_3^*])} \quad (1)$$

where $[HCO_3^-] = [DIC] - [H_2CO_3^*]$ at $pH < 8$ and $K_1 = [HCO_3^-][H^+]/[H_2CO_3^*]$, and $[H_2CO_3^*] = [H_2CO_3] + [CO_2]$.

The analysis of P_{CO_2} and DIC allows pH to be normalized to that which would prevail for equilibrium with the ambient P_{CO_2} in the atmosphere above the lake. The normalization is carried out as follows with the assumption that alkalinity is conservative:

$$pH^0 = -\log \left[\frac{P^0_{CO_2} K^0_H K^0_1 [H^+]_c}{[H_2CO_3^*]K_1} \right] \quad (2)$$

where the superscript refers to the value of a given parameter at mean atmospheric P_{CO_2} and 20 °C, K_H is the solubility of CO_2 and $[H^+]_c$ is calculated from DIC and P_{CO_2} measurements (equation (1)).

A comparison of pH obtained by direct measurement using a glass electrode with that calculated from DIC/P_{CO_2} measurements is shown in Fig. 1. Lake 239 at the Experimental Lakes Area (ELA), northwestern Ontario, is a Canadian Shield lake that was routinely monitored for pH, DIC and P_{CO_2} during the summer of 1982. The dissolved CO_2 content ($H_2CO_3^*$) of surface water averaged 13.5 μmol l^{-1} (normalized to 20 °C) during this period with a standard deviation of 0.3 μmol l^{-1} and was always close to equilibrium with the P_{CO_2} of the atmosphere. The normalized pH results calculated from the DIC/P_{CO_2} data show only a very small scatter around a mean of 7.33. In contrast, the electrode-measured pH data scatter over a range of 0.7 pH units with a mean of 6.93. The pH measurements were made using standard laboratory techniques at the ELA chemistry laboratory[11]. The comparison illustrates both the poor precision and inaccuracy of the pH electrode.

The calculated response of lake 239 surface water to changes in P_{CO_2} is shown in Fig. 2. Extremely low or high P_{CO_2} that can occur during phytoplankton blooms or overturn events, respectively, could produce variations in pH as large as 2 pH units (100-fold H^+ activity). Therefore, even if the *in situ* pH could be electrometrically measured accurately, time trends in acidity would be hard to detect if the P_{CO_2} fluctuations were not taken into account. However, when the P_{CO_2}/DIC method is used, the calculated pH (equation (1)) can be normalized as in equation (2), thus providing both the *in situ* and equilibrium values from a single set of measurements.

The perturbation of pH resulting from changes in the amount of organic acid anions may be important at lower bicarbonate ion concentrations. If during a given season there is a net production of consumption of 'organic' alkalinity, then the concentration of bicarbonate ion must change in the opposite sense to maintain the charge balance. If the P_{CO_2} remains constant through equilibration with the atmosphere, a change in the $HCO_3^-/H_2CO_3^*$ ratio produces a change in pH in accord with equation (1).

Total alkalinity (ΣaAlk) has been suggested as the best measure of acidification trends in lakes and streams. Because it can be measured with a precision of better than 1%, a reliable value for the free acidity of water at equilibrium with the atmosphere could presumably be calculated using equations (1) and (2). However, organic acid anions may comprise a substantial portion of the total alkalinity[4,12–16]. Therefore, attempts to calculate pH from measured ΣAlk without accounting for this component may be in error, especially at low $[HCO_3^-]$ ($pH \simeq 6$).

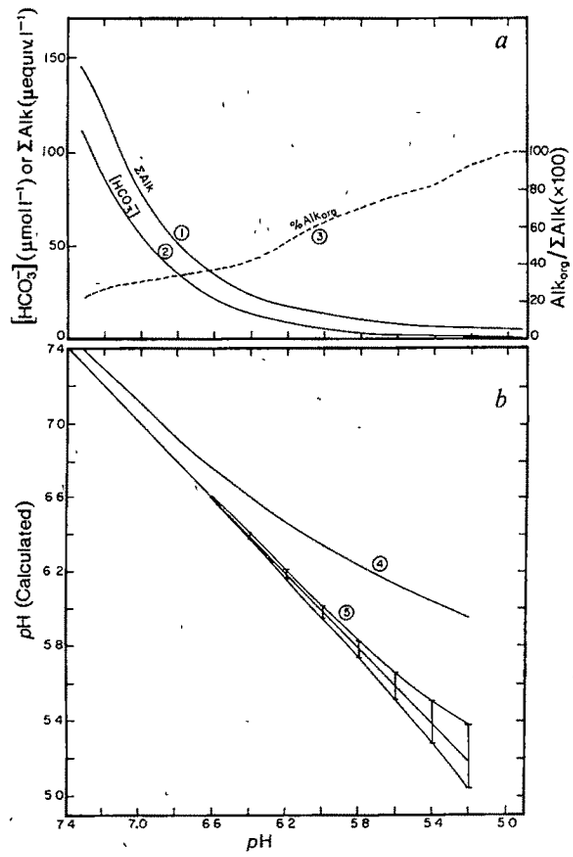

Fig. 3 *a*, The response of ELA lake 239 to acidification is shown by a simple open-system acid titration. Curves 1 and 2 represent the concentrations of ΣAlk and HCO_3^-, respectively, as a function of *p*H. Curve 3 indicates the fraction of ΣAlk made up of organic acid anions. $P_{CO_2} = 340$ μatm at 20 °C. *b*, The *p*H calculated for lake 239 by assuming that $\Sigma Alk = [HCO_3^-]$ is given by curve 4. These calculated *p*Hs deviate from the true values (curve 5) by an increasing amount as the acidification progresses. Error bars on curve 5 represent the analytical uncertainty of the calculated *p*H values using the P_{CO_2}/DIC method.

Consider again ELA lake 239, with an average ΣAlk = 146 μequiv. l^{-1}, $[HCO_3^-] = 113$ μmol l^{-1} and, by difference, $Alk_{org} = 33$ μequiv. l^{-1}. If this lake were to undergo acidification, the components of alkalinity might vary with *p*H as shown in Fig. 3*a*. Because the pKs for organic acids are generally much lower than pK_1 for $H_2CO_3^*$ (refs 12–16), most of $[HCO_3^-]$ will be consumed before there is a significant depletion in organic anions. At *p*H values near 6, ΣAlk is much greater than $[HCO_3^-]$, hence any attempt to calculate *p*H using K_1 will lead to serious error as is shown in Fig. 3*b* by comparing curves 4 (which assumes that $\Sigma Alk = [HCO_3^-]$) and 5 (which represents the *p*H calculated by the P_{CO_2}/DIC method).

The method for monitoring the acidity of lakes using DIC and P_{CO_2} measurements avoids both electrode and organic alkalinity problems and minimizes perturbations caused by fluctuations in P_{CO_2}. Given the variability of our calculated *p*H values for lake 239 (Fig. 1), we could reliably detect a change of >0.1 *p*H units in the equilibrium-acid status of the lake by making a single set of midsummer P_{CO_2}/DIC measurements at any time in the future. Collecting a few samples during a summer would reduce this detection limit by at least a factor of two.

The monitoring strategy described here is not intended for lakes that are already acidified. It is only applicable to waters with *p*H >5.5, below which the difference between DIC (that is, $[HCO_3^-]+[CO_2]$) and $[CO_2]$ becomes too small to permit accurate determinations of $[HCO_3^-]$. For lakes now on the brink of serious acidification effects (that is, in the *p*H range 5.5–7.0), our method provides a far more reliable and sensitive indicator of acidification trends than can be obtained by any other method.

Our proposal requires only that the determination of P_{CO_2} and DIC be included in the existing monitoring programmes.

We thank T. Takahashi and R. Hesslein for valuable discussions. Some of the analyses reported here were performed by the ELA chemistry group under the direction of M. Stainton and G. Linsey. This work was supported under the auspices of NSF grant DEB 80 17639 and the Department of Fisheries and Oceans, Canada.

Secular climate change in old-growth tree-line vegetation of northern Quebec

Serge Payette, Louise Filion, Line Gauthier & Yves Boutin

Centre d'études nordiques, Université Laval, Sainte-Foy, Québec, Canada G1K 7P4

The climate of the Northern Hemisphere changed during recent centuries, as shown by the Little Ice Age episode[1] and the warming trend of the past 100 years[2,3]. The ecological impacts of these changes have yet to be evaluated in several terrestrial ecosystems, incorporating direct evidence such as detailed botanical field observations[4]. We report here results of the analysis of a ~600-year response of a lichen–spruce woodland to this long-term trend, which are thought to be the first extensive illustration of these impacts in the Subarctic. It suggests that tree-line vegetation is in a dynamic equilibrium with climate in the absence of other external disturbances; this is emphasized by spruce reaction through phenotypic adaptation—a shift from stunted individuals (krummholz) to normal trees (forest)—and differential regeneration. This study produces evidence that marginal northern forests can persist through time and that successional processes, in the absence of fire, perpetuate the original lichen–spruce facies. The longest tree-ring chronology (AD 1398–1982) yet available in eastern North America was constructed from living and dead spruces found in the lichen woodland of our study.

It has been shown recently[5] that the extensive treeless areas within the northern Québec Forest–Tundra zone are the result of late Holocene fire disturbance and climatic change. Exceptions to this deforestation trend are found around the tree line near Hudson Bay, where old-growth coniferous vegetation persisted without any fire for several centuries. One of the best examples is a lichen–black-spruce (*Picea mariana* (Mill.) BSP.) woodland, 3–4 km long, about 10 km south of the present tree line in the Bush Lake area (57°47'N, 75°45'W). This stand occupies a well-drained site that burned for the last time around 900–850 yr BP, in the immediate vicinity of the sampling area, as indicated by two radiocarbon-dated charcoals found below the organic layer (UQ-163: 890 ± 55 yr BP; UQ-158: 850 ± 85 yr BP), that is, around dendroyears AD 1075 ± 57 and 1160 ± 86 using the radiocarbon-dated calibration curve of Stuiver[6].

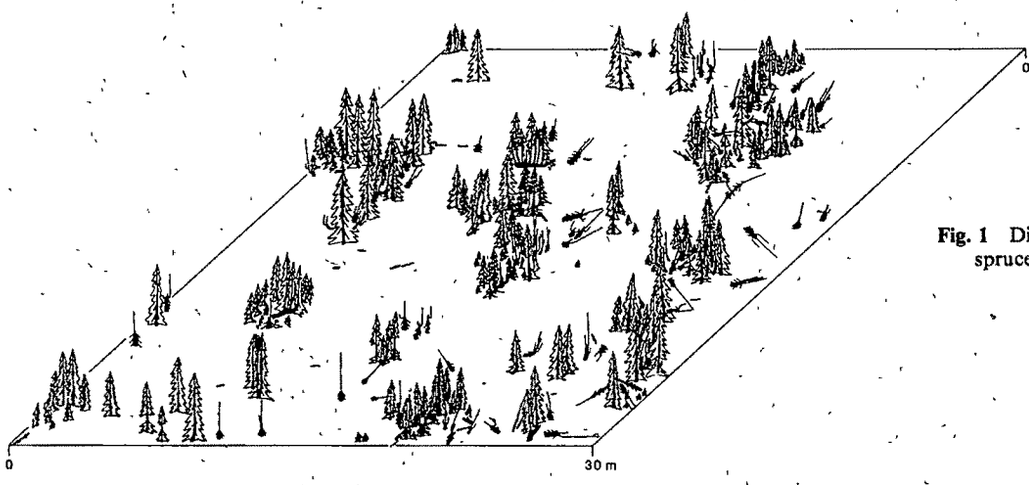

Fig. 1 Distribution of the living and dead spruces within the 900 m² quadrat.

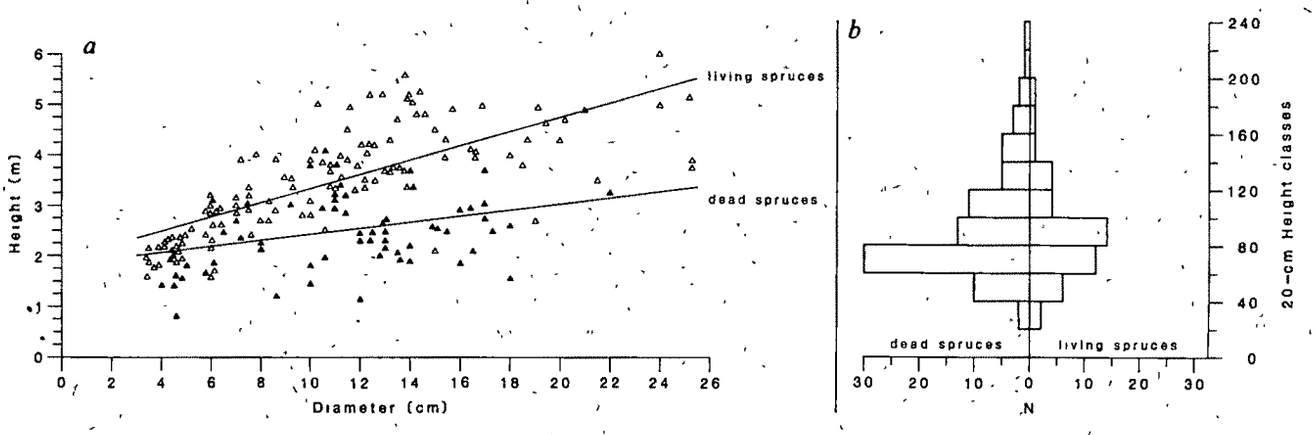

Fig. 2 *a*, Relationship between basal stem diameter and total height in living (△, $y = 1.9621 + 0.1391x$, $r = 0.74$) and dead (▲, $y = 1.8203 + 0.0604x$, $r = 0.35$) spruces. Differences in the regression slopes are statistically significant at the 0.001 level. *b*, Height (20-cm class) above ground of multiple-stem levels and branch leaders. The bulk of multiple-stem level distribution in dead and living spruces is respectively around 60–80 and 80–100-cm classes, which suggests an overal difference of 20 cm in depth of snow cover; the dead spruces were probably in an environment with less snow compared with living spruces.

The woodland consists of dominant living low spruce trees along with shrubby or subarboreal stunted leaning dead spruces (Fig. 1). We have postulated that the two contrasting growth forms developed under different climatic regimes; the abundance of dead spruces in such an environment made us suspect that the woodland was growing old in the absence of external disturbance—a unique situation for evaluating the stability of marginal northern forests.

A 900 m² (30m×30m) quadrat was used to determine the spatio-temporal development of the coniferous vegetation (Fig. 1). All the living and dead spruces were mapped and their growth forms, such as arboreal, subarboreal and shrubby, described (Fig. 1). Diameter at stem base, total height and winter damage expressed by morphological traits such as above-ground multiple-stem and branch leaders, along with bare (leafless and branchless) stems above snow cover, were measured on all individuals (Fig. 2). The origin, by layering or by seed, was determined from stem morphology, stem distribution and below-ground branch connections[7]. Samples of living spruces were taken at stem base and at the multi-stem level that is thought to mark the mean winter snow position. The dead stems were sampled immediately above the level of decomposition (stems rotted near the ground), generally 30–100 cm above ground level, and also at the snow-air interface and stem apex; although the real age, that is, the age of the stem at the ground level, could not be determined on these samples, the data were used to estimate the date of stem death.

Tree-ring measurements were performed on fine-sanded cross-sections with a standard micrometer (0.01 mm precision). The dating of dead stems was made possible because of the very good condition of preservation of these samples and the presence of such diagnostic light rings of very few latewood cells as those dated to AD 1593, 1816 and 1817 (L.F., S.P. and L.G., unpublished results). The tree-ring chronology was extended to AD 1398 by cross-dating. The oldest black spruce was 504 yr old, which extends the known longevity for that species[8] by at least 200 yr. The chronology was built from 39 radii belonging to 26 stems. Reaction wood[9] was common in leaning stems, but measurements made on the different sets of tree-rings, with or without compression wood, showed the same growth; samples with a changing direction of compression wood were rejected. Missing or incomplete rings were frequent, especially for the period 1600–1610, and annual rings were particularly narrow between 1398 and 1880, virtually at the lower limit of spruce growth. Because of these anatomical and morphological ring characteristics, the chronology has been based on the arithmetical mean of the 39 series. In addition, an overall-growth curve was produced from multiple polynomial fitting of the 39 series.

The 233 stems recorded consist of 136 living and 97 dead specimens (Fig. 1). Striking size differences were found between the two groups, especially with increasing size of basal stem diameter (Fig. 2*a*); large dead stems reached about 3.5 m in height, whereas large living spruces were 1–1.5 m higher. Living spruce boles are predominantly erect, radially symmetrical and, occasionally, eroded at the snow–air interface level, whereas dead spruces showed oblique and anisomorphic boles together with multiple-stem leaders located at a former snow–air interface

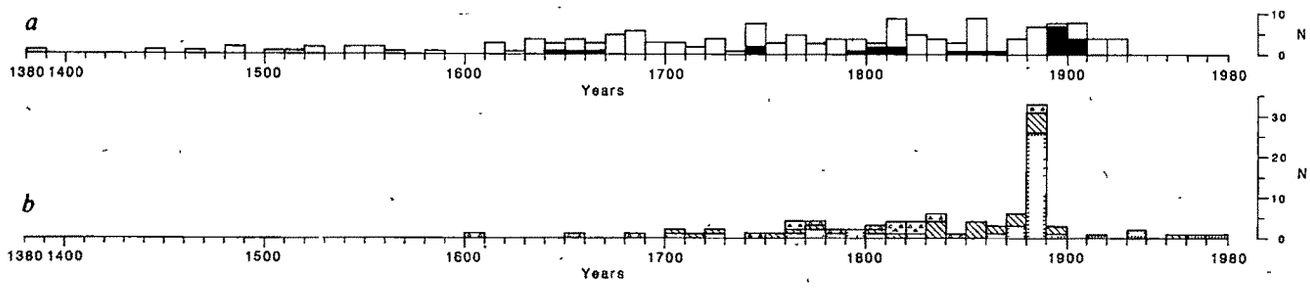

Fig. 3 *a*, Age structure of living spruces according to origin (white: layering; black: seed). Age distribution among 10-yr classes is thought to cover the difference between real stem age and stem age at the sampling level. Because the age structure is of the present-day (sampling year in 1983) living individuals, the data cannot reliably be extrapolated back in time. Absence of seedling establishment in the climatically favourable period of the 1930s and 1940s appears to be related to quadrat sampling size; areally small clustered cohorts from that period were found a few metres away, but are not incorporated here in the age structure histogram. We think that the naturally low seedling regeneration rate of this lichen woodland during the past centuries could be estimated more properly with larger sampling units. *b*, Mortality dates of spruces (triangle, death of stem apex; hatched, death of stem at the snow-air interface; dot, death of basal stem, that is, below the snow-air interface). 10-yr class. Mortality dates were estimated only for well-preserved outer stem sections, which give the overall mortality trend of established stems during the past two centuries, but not for previous centuries because of an unknown proportion of decomposed stems.

level (Fig. 1). Frequency distribution of postulated snow-air levels between living and dead spruces suggests that the former were growing in an environment with less snow (Fig. 2*b*), under colder conditions probably associated with frost desiccation and deep-freezing of exposed leaves[10,11].

The all-aged structure of the living spruce population (Fig. 3*a*) indicates continuous development during the past centuries, mainly through layering. Only 16% were identified as seed-origin individuals and 50% of these germinated between 1890 and 1910; the remaining seed population established episodically between 1640 and 1870. Layering occurred continuously throughout the past 600 yr (young layers were not sampled within the quadrat). Mortality was also an important component of the spruce population dynamics, particularly between 1700 and 1980 (Fig. 3*b*). Tree-ring analysis of dead stems revealed differential mortality according to the position of the living tissues relative to snow cover. Above-snow stems often died 100 yr earlier than stem sections located at the snow-air interface; death of the trunk followed within a few decades. An important feature here is the rather sudden mass mortality of spruces during a 10-yr period, between 1880 and 1890, when 57% of the subfossil population died. At that time, 70% of the dying spruces were older than 200 yr and 30% were older than 250 yr. Senescence appears to be one factor explaining the mass mortality; considerable reduction of the photosynthetic structure is a possible factor, as suggested by the very low growth during many decades before death. The cost of reproduction[12] may have also some influence here on the overall vigour of the old-aged and moribund spruces at a time when cone production was stimulated. In fact, this period of mass mortality coincides with a short interval of seedling establishment (Fig. 3*a*, *b*). Other factors such as pathogen attacks (for example, fungus, insects) remain uncertain.

Tree-ring responses to the long-term developmental process of spruce vegetation are clearly expressed in the 600-yr chronology (Fig. 4). Two periods of different duration are shown, a slow-growth period between 1398 and 1890 and a faster growth period afterwards. Very narrow rings were formed during the first period, especially around 1420–1435, 1480–1495, 1600–1610, 1690–1700, 1825–1830, 1835–1840 and 1855–1860. Most of the period corresponds to the Little Ice Age, particularly between 1550 and 1850 (ref. 1). Yearly variations in ring width were not important except before 1520; but, more data are needed to evaluate thoroughly the period before 1550 where short intervals of larger tree rings and presence of tree-like subfossils suggest less severe climates than during the Little Ice Age. Low stature and limited photosynthetic mass during that period could have caused variability in tree-ring responses, although the overall ring pattern is one of climate suppression on tree growth. Large tree-ring widths during the second period are associated with milder climates well documented by instrumental records[2]. Yearly variability is higher here and tree growth climaxed in the 1930s and early 1940s, during maximum warmth[2]. A reversal in the growth trend occurred afterwards and corresponds to the post-1940s cooler conditions registered in the Northern Hemisphere, except for a brief interval between 1950 and 1960 (ref. 14).

The Bush Lake lichen woodland represents an outstanding example of vegetation response to climate change in the absence of other known external disturbances. The discovery of older dead spruces may extend the chronology to 800–900 yr. The ecological impacts of the Little Ice Age climate were significant in terms of spruce morphology and regeneration, because the population formed a krummholz (stunted spruces) of predominant long-lived layers. However, episodic seedling establishment occurred during short intervals, such as 1640–70, 1740–50, 1800–20 and 1840–60. An important conclusion here is that krummholz may regenerate sexually during short milder periods, as suggested by the tree-ring chronology. Another is that shifting from krummholz to forest expresses a major change towards milder conditions culminating during this century. This shifting in growth habit appears to be a large-scale phenomenon observed throughout the northern Québec Forest–Tundra. It is also important to consider that the time lag in growth-form shifting, attributable to change in climate, is determined in part by the time when the critical position of apical buds and needles relative to the winter snow pack is reached. This suggests that winter climate defines the climate threshold where apices of growing spruces, or exposed buds, needles and twigs, located at the snow-air interface, experience harsh conditions that eventually discriminate the future growth forms among long-lived individuals. Seedlings established during the past two centuries that have developed into tree form, probably reached the snow-air interface when the winters became somewhat milder. Therefore, we may conclude that the time lag between a change in

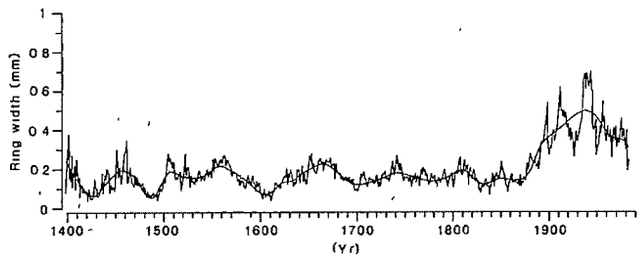

Fig. 4 Tree-ring chronology, AD 1398–1982, built from 26 stems of living and dead spruces (mean ring width in mm from 39 radii). Also included is the long-term growth curve derived from polynomial fitting[13].

climate and phenotypical spruce response is many years, sometimes a few decades, a situation controlled in growing spruces by apical-bud residence time into the critical snow–air interface. The transition from the Little Ice Age to the present regime was also characterized by mass mortality in old-aged spruces that were not able to take advantage of the new favourable climates and by the replacement of these spruces by seedlings that later formed normal trees. Although we know of no other similar example of mass mortality in northern forests that is not caused apparently by insect outbreaks, we believe that our results suggest a possible link with the changing ecological conditions that occurred at the end of the nineteenth century, when old spruces with limited photosynthetic mass were already engaged in a lengthy process of dying. A closer look at the biological effects of energy expenditure in senescent or moribund spruces during a period of climate recovery, could lead to a better understanding of this intriguing phenomenon. Finally, we conclude that the overall developmental sequence described here indicates that lichen woodlands can regenerate sexually in the absence of fire disturbance and do not degrade into tundra vegetation as suggested elsewhere[15]. It illustrates the importance of vegetation inertia, in a fire-free ambience, for persistence of communities in cold environments characterized by episodic sexual regeneration. From a climatological viewpoint, the conditions expressed by this old-growth vegetation were probably associated during the Little Ice Age with very cold windy winters with thin snow cover and cool moist summers and, during the recent warming, with milder and snowier winters (a postulated 20-cm mean increase in snow depth based on growth forms, Fig. 2*b*) and mild summers. The 600-yr chronology exhibits the marked differences observed among dead and living spruces and it may be considered as a typical example of secular climatic change in the eastern part of the North American Subarctic.

We thank Professor J. C. Ritchie (Toronto) for revising our manuscript and for useful suggestions. This study has been supported financially by the Natural Sciences and Engineering Research Council of Canada (NSERC) and the Ministère de l'éducation of Québec (FCAC Program). We also thank Mr. Ivan Grenier for drafting the figures, Dr Paul Comtois for field assistance.

Isotope assessment of Holocene human diets in the southwestern Cape, South Africa

Judith C. Sealy & Nikolaas J. van der Merwe

Department of Archaeology, University of Cape Town, Private Bag, Rondebosch, 7700 Cape Town, South Africa

Models of seasonal mobility to exploit seasonally abundant food sources have been proposed for prehistoric hunter-gatherers in many parts of the world[1–3]. Some such hypotheses involve fundamental and insufficiently tested assumptions about the nature of both hunter-gatherer societies and the archaeological evidence that they leave. The present study is an independent test of such a hypothesis proposed for the southwestern Cape of South Africa. In this strongly ecologically differentiated area there are four distinct ecological zones that would have offered four different sets of resources to prehistoric people. Obvious modern seasonal fluctuations in these resources, plus a considerable amount of archaeological evidence, led to the suggestion that prehistoric hunter-gatherers moved in a regular seasonal cycle across the zones[4,5]; this would have allowed them to make maximum use of temporarily plentiful plant and animal foods in some areas, while avoiding lean periods in others. However, as reported here, direct measurements of food intake, as reflected in the stable carbon isotope ratios of archaeological human skeletons, reveal that this was not the case. The implications of this study extend beyond the relevance to local archaeology to more general questioning of the ways in which archaeological data should be used to generate hypotheses.

Figure 1 shows the four north–south ecological zones of the southwestern Cape: the Atlantic shoreline, the temperate coastal plain, the Fold Mountain Belt and the semi-desert Karoo. Each zone has a different geology, rainfall and vegetation. Holocene archaeological sites in the area contain quantities of plant and animal food waste, much of it identifiable as having been collected in the summer (in the mountains) or in the winter (on the coast).

Inland sites are rich in the remains of edible plants: corm casings from starchy Iridaceae corms (at their most palatable

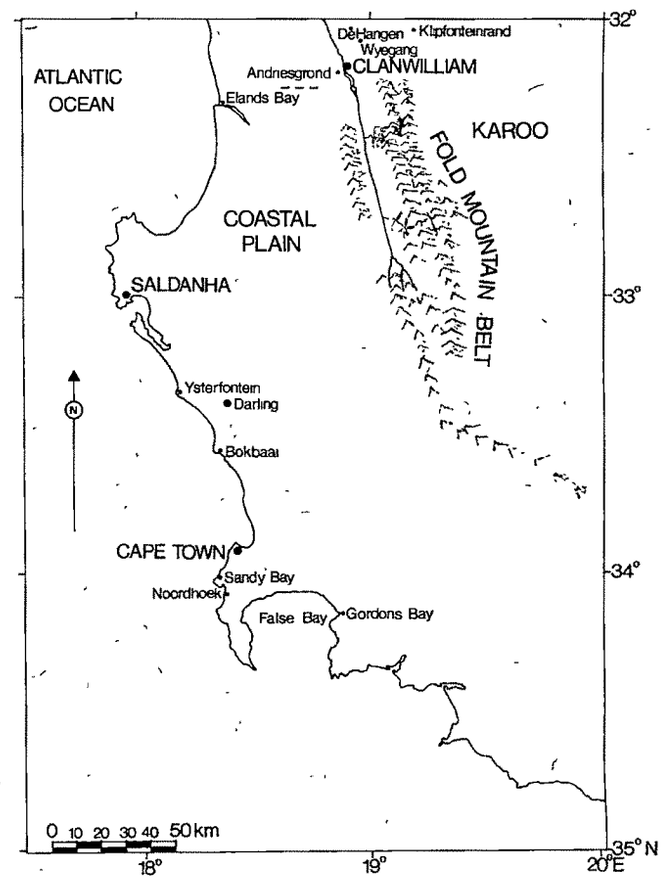

Fig. 1 Map showing geographical features of the southwestern Cape and localities of the skeletons listed in Table 1.

in late summer) and seeds from the fruits of summer-fruiting plants. The faunal assemblages are dominated by tortoise bone (tortoises are most active, and hence easiest to collect, in summer). The second most common animal is the rock hyrax (*Procavia capensis*). Examination of the stage of tooth eruption in juvenile hyrax mandibles reveals that almost half of those from

All pottery so far found in the area post-dates 2,000 yr BP; its association with skeletons therefore constitutes an approximate guide to their ages. Some of these skeletons (those from Saldanha South) lie outside the area for which the seasonal mobility hypothesis was originally formulated. They are included mainly to demonstrate the consistently positive character of coastal isotope values. Pta, radiocarbon dates from the Pretoria laboratory; OxA, dates from the Oxford radiocarbon accelerator.

the cave of De Hangen (the site with the largest faunal assemblage) were probably killed between October and May. Finally, historical accounts of meetings between European travellers and 'bushman' hunter-gatherers in the area all refer to summer encounters.

The coastal segment of the seasonal round is represented at sites such as Elands Bay Cave: like most coastal sites, this has few plant food remains but large quantities of limpet and mussel shells. If shellfish were a common, reliable resource taking the place of plant foods as a coastal staple[4–6], Parkington[4] suggested that it would have been safer to exploit them in winter. Winter outbreaks of the poisonous dinoflagellate *Gonyaulax catenella* are less common than summer ones; these diatoms render filter-feeding shellfish (such as mussels) toxic to man. The most common marine mammal from the Elands Bay deposits is the Cape Fur Seal (*Arctocephalus pusillus*). Young seals are born in November and nearly all the excavated mandibles are those of yearlings that died between July and October; seasonal rings on a small sample of canines from adult male seals obtained from the same site apparently also reflect this short time period[7]. The bones of several species of birds that are winter visitors to the nearby Verlore Vlei estuary (for example, flamingos) are found throughout the Holocene levels of the cave deposits. Winter is also the time when the Vlei, swollen by winter rains, used to break through into the sea, carrying with it organic material that would have attracted fish such as the white steenbras (*Lithognathus lithognathus*), common in the cave deposits.

Thus, there is a considerable amount of archaeological evidence for summer occupation at De Hangen and winter occupation at Elands Bay Cave. Inland and coastal sites have been seen as different segments of one integrated subsistence economy. People supposedly moved between the various resource zones in such a way as to exploit peaks in animal and, particularly, plant resources, while avoiding troughs. Recently, Parkington[5] has fitted his seasonal mobility hypothesis more securely into a chronological framework. He now expects that it will be found to apply, in the form outlined above, mainly in the period between 4,000 and 2,000 yr BP; before this, from 8,000 to 4,000 yr BP, there was a hiatus in the occupation of Elands Bay Cave and of at least one other site nearby, while after 2,000 yr BP the system was probably seriously disrupted by the emergence of pastoralists with domesticated animals on the coastal plain.

The seasonal mobility hypothesis is directly testable by measuring the $^{13}C/^{12}C$ ratio. The use of $\delta^{13}C$ measurements ($\delta^{13}C_{sample} = [^{13}C/^{12}C_{sample}/^{13}C/^{12}C_{standard}] - 1 \times 1{,}000‰$) as a source of dietary information is now an established archaeological technique[8,9]. Most previous studies incorporating such measurements have, however, been limited by having to use global averages for the isotope ratios of the dietary base. In the study reported here, we began by analysing samples of all the foods that we know were important in the diet of prehistoric humans in the southwestern Cape. We also included a cross-section of other edible organisms that would leave no trace in the archaeological record.

The results of the analyses form very clear patterns, which are presented in full elsewhere[10]. In summary, the mean $\delta^{13}C$ value of the marine-based foods consumed by people living on the coast (shellfish, crayfish, fish, seal and seabird meat) is $-15.6 \pm 1.6‰$ (range = −12.3 to −19.4‰, $n = 29$). The edible parts of terrestrial plants have a mean $\delta^{13}C$ of $-25.4 \pm 1.8‰$ (range = −22.3 to −29.2‰, $n = 26$) whereas terrestrial animal meat has a mean of $-23.6 \pm 1.3‰$ (range = −20.9 to −25.8‰, $n = 15$). Therefore, a marine-based diet has an isotope 'signature' substantially different from a terrestrially based one; this difference would be reflected in the bones of people consuming these foods (the absolute values for bones being some 5‰ more positive as isotope discrimination proceeds stepwise along trophic levels).

Next, we analysed several archaeological human skeletons, some of which were found at the coast and some in the mountains. If they represent a seasonally transhumant population they should all have broadly similar $\delta^{13}C$ values intermediate

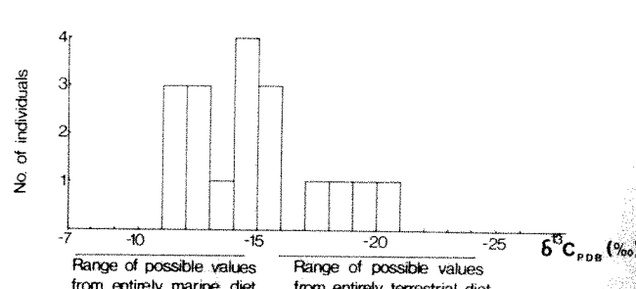

Fig. 2 Histogram of the results given in Table 1.

between the values for purely marine and purely terrestrial diets; it is obvious from Table 1 that this is not the case. Instead, the coastal skeletons reflect a predominantly marine diet and the inland skeletons an almost entirely terrestrial diet. Clearly, whatever seasonal round either group might have engaged in, they do not represent segments of the same subsistence economy.

The coastal skeletons show $\delta^{13}C$ values that range from almost entirely marine-derived (−11‰) to values which could reflect up to 50% terrestrial food composition (−15‰). We consider that the sample is as yet too small to detect geographical or chronological patterning, though this will be one of the principal aims of further work. The most interesting point is not that some coastal people consumed terrestrial foods (available, in any case, near the shore) but that, in direct contrast to nearly all models of prehistoric coastal subsistence[4–6,11], a significant proportion of the coastal population consumed an entirely marine diet and so must have spent all its time on the shore. Seventeenth-century European settlers described 'strandlopers' doing this[12]; from the isotope data it seems to be a pattern of life extending back at least as far as the beginning of the Holocene.

This result may seem surprising in view of the extremely plausible arguments for seasonal mobility summarized above. Closer examination of these arguments, however, reveals that although the evidence is consistent with such a hypothesis, it is also extremely inconclusive[10]. Although people certainly were living in the mountains in the summer and on the coast in winter, the hypothesis rests on the unproven assumption that they were the same people and that they were not living in the mountains in winter, or on the coast in summer—this would be much more difficult to demonstrate, but it is essential to do so to postulate population movement between the two areas. We suggest that comparable hypotheses formulated for other parts of the world might benefit from similar critical re-examination.

We thank John Parkington, who suggested this project, provided the archaeological samples, and partly financed the project through his Spatial Archaeology Research Unit, supported by the Human Sciences Research Council of South Africa. Other colleagues also gave us free access to ideas and unpublished data, and we thank the many people who helped to collect samples. We thank John Vogel of the CSIR in Pretoria and the Radiocarbon Accelerator Laboratory at Oxford University for the radiocarbon dates. Additional financial support was provided by the Council for Scientific and Industrial Research and the Harry Oppenheimer Institute for African Studies at the University of Cape Town.

Evidence for echolocation in the oldest known bats

Michael J. Novacek

Department of Vertebrate Paleontology, American Museum of Natural History, New York, New York 10024, USA

The earliest-known bats are represented by excellent fossil material, including virtually complete skeletons of *Icaronycteris index* from the early Eocene (50 Myr BP) of western Wyoming[1,2] and *Palaeochiropteryx tupaiodon* from the middle Eocene (45 Myr BP) 'Grube Messel' of western Germany[3,4]. These taxa have been closely allied[1,5] with Recent Microchiroptera, a suborder of diverse bats noted for their powers of ultrasonic echolocation[6]. A problem with this relationship is the alleged absence in the Eocene forms of specializations in the auditory region[7] and other aspects of the skeletal system[1,2]. It has been proposed, therefore, that the oldest bats are members of a group more primitive and possibly ancestral to the Microchiroptera and the visually oriented Megachiroptera[8]. Previously undescribed specimens now show, however, that *Icaronycteris* (Fig. 1) and *Palaeochiropteryx* (Fig. 2) share special basicranial features with microchiropterans which suggest comparable refinement of ultrasonic echolocation. These results support the theory that a sophisticated sonar system was present in the earliest records of microchiropteran history.

The ultrasonic echolocation of living microchiropterans has been related to the structure of the middle-ear ossicles[9–15], laryngeal-hyoid apparatus[16,17] and the cochlea[9,14,18–20]. The ear ossicles are not well preserved in *Palaeochiropteryx*, but in *Icaronycteris* there is a partial malleus with a large orbicular apophysis (Fig. 1). This rounded process is well developed in microchiropterans, but is absent or weak in non-echolocating megachiropterans[9–13]. In microchiropterans the ossicles are tightly articulated for optimal tuning at ultra-high frequencies[12–14]. Mechanical analysis[13] suggests that the orbicular apophysis shifts the centre of mass of the malleus away from the rotational axis of the ossicle chain, increases the moment

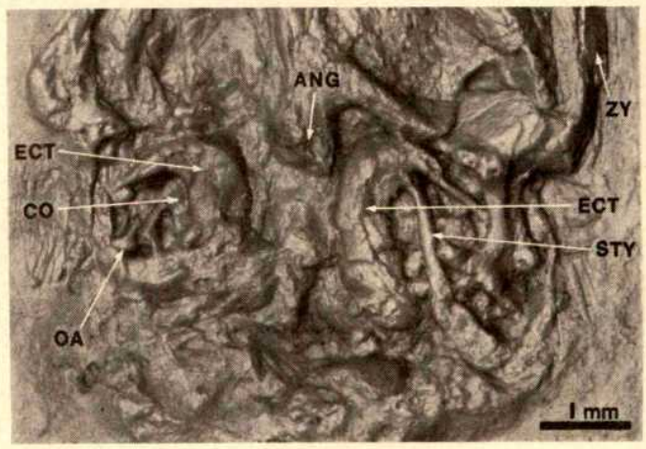

Fig. 1 Ventral aspect of cast of posterior skull of *Icaronycteris index*, University of Wyoming (UW) 2244. ANG, angular process of lower jaw; ECT, ectotympanic ring; CO, cochlea; OA, orbicular apophysis of malleus; STY, stylohyal; ZY, zygomatic arch. In this specimen the stylohyal lies lateral to its normal position ventral to the ectotympanic.

of inertia and lowers the natural frequency of the ossicle system. The apophysis may therefore contribute to the attenuation of natural frequencies that might otherwise be too high, even for echolocating bats[13].

Icaronycteris (Fig. 1) and *Palaeochiropteryx* (Fig. 2) both have a well-developed stylohyal element. In megachiropterans, as in most mammals, the stylohyal is usually a weak filamentous structure easily lost in macerated skulls[21]. The stylohyal in microchiropterans is the site of well-developed muscles that constrict the pharynx and brace the hyoid apparatus[16,17]. The hyoid stabilizers allow the extrinsic laryngeal muscles to pull from the hyoid and move the larynx forward[17], an action that precedes the emission of a series of high-frequency pulses[22]. The stylohyal, then, is an important component of a laryngeal-hyoid apparatus, whose variable design influences the charac-

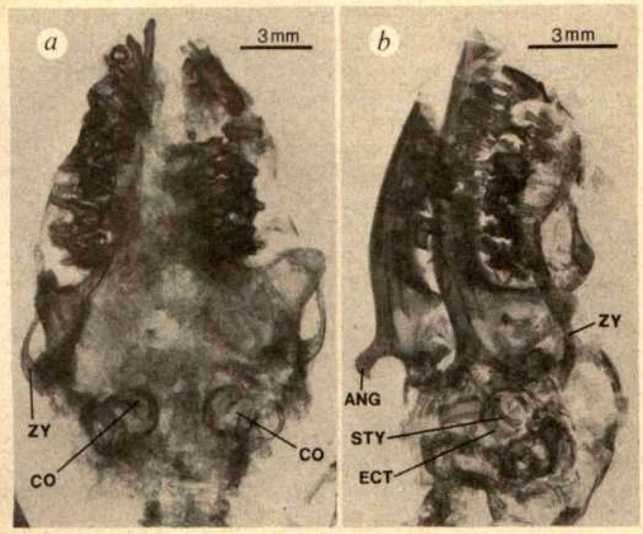

Fig. 2 *Palaeochiropteryx tupaiodon.* Positive prints of radiographs of a dorso-ventral view of Senckenberg Naturmuseum und Forschungsinstitut SMF-ME 788-B (*a*) and a lateral view of SMF-ME 1127 (*b*). Abbreviations as in Fig. 1.

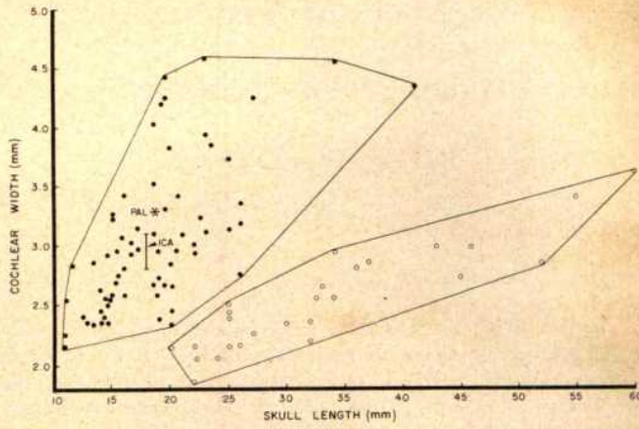

Fig. 3 Plot of maximum width of cochlea (ordinate) against skull length (abscissa) for 96 species of Microchiroptera (●), Megachiroptera (○), *Palaeochiropteryx* (*) and *Icaronycteris* (vertical line represents range of error in estimate of maximum cochlear width). Points represent 17 of 19 Recent bat families (two monotypic families of microchiropterans, the Myzopodidae and Craseonycteridae, are omitted). Convex polygons define the outer boundaries of values for each of the two suborders. Cochlear width has a weaker correlation and more positive allometry with skull length in microchiropterans ($r = 0.64$, slope = 0.80) than in megachiropterans ($r = 0.92$, slope = 0.30).

teristics of high-frequency vocalizations in different bat species[17].

The most striking resemblance between these Eocene bats and living microchiropterans is in the large relative size of the cochlea. The dimensions of this structure are easily determined in *Palaeochiropteryx* (Fig. 2). In *Icaronycteris*, the cochlea is less well preserved, but an estimate of its size can be made from measurements between auditory structures adjacent to the cochlea (Fig. 3). The maximum width of the cochlea is a meaningful functional parameter because it is equal to the maximum width of the basal turn, that region of the cochlea especially receptive to high-frequency vibrations in adult mammals[14,19,20,23–25]. A plot of maximum cochlear width against skull length for 96 species of bats shows no overlap between Megachiroptera and Microchiroptera, and supports the observation[14,15,18] that the cochlea in microchiropterans is unusually large relative to the size of the skull. The great expansion and increased torsion of the cochlea in these bats is accommodated by a unique pattern of arrested ossification of the petrosal and adjacent elements during ontogeny[26]. *Palaeochiropteryx* and *Icaronycteris* fall well within the range of relative cochlear size for Microchiroptera and exceed values for several living species within this suborder (Fig. 3). Thus, the implication is strong that these early bats share with living echolocating bats a cochlea of comparable ontogeny and function.

The basicranial evidence reviewed here supports the contention[1,5] that the oldest bats share several derived features with microchiropterans and are members of that group. Nevertheless, the fossil bats, particularly *Icaronycteris*, retain a number of very primitive features in the sternum and distal appendages[1,2,8]. This mosaic of traits suggests that the development of a sophisticated auditory and laryngeal system preceded the acquisition of certain other structures. Ultrasonic echolocation and its correlative morphology have been demonstrated in all living microchiropterans so far studied[14,15,26–28]. Thus, evidence from living taxa and the fossil record are consistent with the argument that ultrasonic echolocation is a primitive sensory mode for microchiropterans.

Echolocation also occurs in the megachiropteran genus *Rousettus* and in certain cetaceans, seals, insectivorans, rodents, birds and even some blind humans[28]. Microchiropterans are unique, however, in producing echolocation calls that are structured in frequency changes over time, a mode particularly effective in hunting volant, nocturnal prey. Other echolocators, including *Rousettus*, use transient, broad-band clicks[28]. Moreover, no other mammalian group shows an auditory architecture and ontogeny closely similar to that of microchiropterans[26]. It seems unlikely, then, that ultrasonic, time-structured echolocation was an early or primitive condition for all bats, only to be secondarily lost in the visually oriented megachiropterans. A more plausible notion is that ultrasonic echolocation was derived within bats, possibly from a condition where low-intensity, broad-band echolocation was used primarily for communication and gathering of habitat information, while vision, olfaction and direct audition (listening to sounds of prey) were used in the search for food[28]. This transition, according to the evidence reported here, occurred earlier than 50 Myr ago, the time of first appearance of bats in the fossil record.

I thank J. Franzen (Senckenberg Museum) and J. A. Lillegraven (University of Wyoming) for loan of the fossils and M. C. McKenna, A. Wyss, M. Norell, K. Koopman, L. Flynn and J. Flynn for comments. H. Tuengerthal, R. Gooris, L. Meeker and C. Tarka prepared the figures. Research was supported by the Frick Laboratory Endowment Fund (American Museum of Natural History).

Course correction circuitry translates feature detection into behavioural action in locusts

H. Reichert, C. H. F. Rowell & C. Griss

Department of Zoology, University of Basel, Rheinsprung 9, CH-4051 Basel, Switzerland

Like other flying animals, locusts must maintain course stability despite turbulence and motor errors. Accordingly, they must detect course deviations and then correct them. The compound eyes, the ocelli and the cephalic wind hairs all detect different sensory consequences of flight instability[1–3], and descending interneurones bring this information to the thorax[4–9]. One such interneurone of this population (the tritocerebral commissure giant neurone) is known to elicit correctional steering[10]. Here we characterize three additional pairs of descending deviation detector neurones and show how their information is translated into altered drive to the flight motoneurones. The central pattern generator for flight[11–13], modulated by proprioceptive feedback[14], gates the signal of the detector neurones in thoracic premotor interneurones[9], ensuring that the flight motoneurones are affected only during flight. Further, the gating process transforms the phase-independent information of the deviation detectors into a phase-dependent signal modulated at wing-beat frequency, and transfers it to those flight motoneurones active at the time and appropriate to the corrective action required.

We recorded intracellularly, with dye-filled microelectrodes, from the three pairs of descending interneurones and their identified postsynaptic cells in the thoracic ganglia of locusts (*Locusta migratoria* (L. 1758)) during flight motor activity[12], to correlate their morphological and functional characteristics. Course deviations were simulated by an artificial horizon, provided with a central wind jet (Fig. 1*b*). In some experiments the ocelli were stimulated independently via light pipes that excluded light from other sources[9]. These procedures established the role of the three interneurones as highly specific absolute deviation detectors, which integrate sensory information from the compound eyes, the ocelli and the wind hairs. Table 1 summarizes the excitatory input characteristics of the three cells.

We have named these interneurones DNI, DNM and DNC, so called because they receive input from the ipsilateral, medial and contralateral ocelli, respectively (Fig. 1*a*). All have been in part described previously, but because of confusion in the literature (Table 2), we find it necessary to rename them. Input from the compound eye confers on these cells sensitivity to large field movement and to direction of movement. Figure 1*c* shows an example of the specific nature of compound eye input. A simulated roll deviation presented to the compound eyes results in excitation of the left DNC only if the roll is clockwise and away from the horizontal position. For a roll of this specific type of given amplitude, the response of the cell increases with increasing divergence of the artificial horizon from the horizontal. The cell does not respond to a clockwise roll towards the horizontal, nor does it respond to an anticlockwise roll towards or away from the horizontal. This cell also responds with similar specificity to deviations in the pitch and yaw axes (Table 1). The optimal combination of compound eye stimulation for this cell is what the animal would experience during a diving, banked turn to the side contralateral to the axon.

Excitatory input from the wind hairs or ocelli complements the compound eye input in an aerodynamically compatible and directionally specific manner. For example, a cell which is excited by a visually simulated yaw to the left is also excited by wind directed towards the animal's head from the right which would in nature accompany this yaw. If compound eye input causes the cell to be excited by a simulated clockwise roll, it

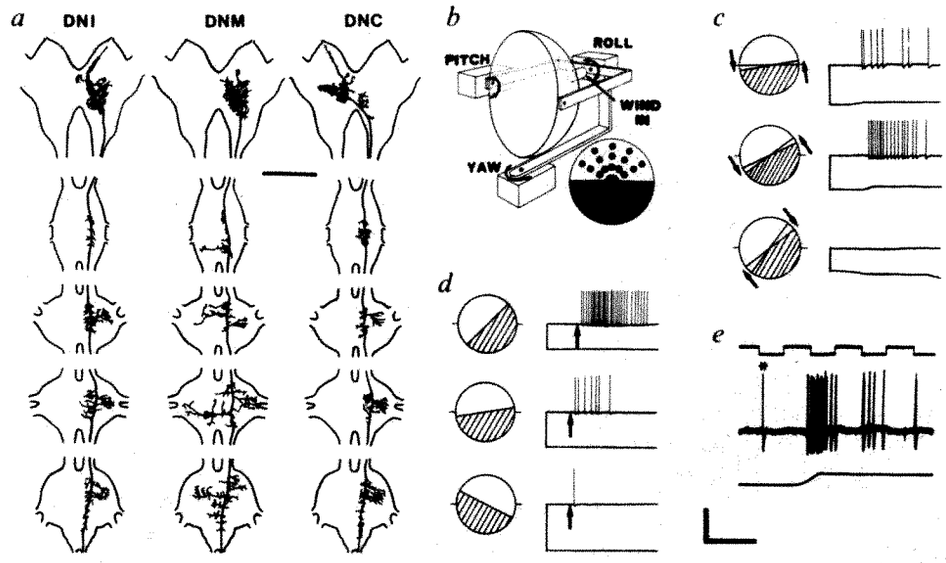

Fig. 1 The descending deviation detector neurones DNI, DNM and DNC. *a*, Morphology and nomenclature. The units are so named because they receive input from the ipsilateral, medial and contralateral ocelli, respectively, where ipsi- and contralateral are defined as the side on which the axon of the interneurone runs. This is clearly reflected in the location of the input arborizations in the brain. In the remaining ganglia, DNM is distinguished by its bilateral projection, while DNI and DNC project only unilaterally and are very similar in structure. All three units are paired. We distinguish individual units as left and right with reference to the connectives in which the axon descends to the thorax. Drawings are based on 20–30 successful intracellular fills (either Lucifer yellow[35] or hexamine cobalt chloride with subsequent intensification[36]) of each unit. Scale bar, 800 μm. *b*, Stimulus apparatus producing simulated course deviations. The animal's head was placed at the centre of a remotely steerable translucent hemisphere, on which was painted the opaque pattern shown, representing an artificial horizon and a structured visual field; the whole was illuminated diffusely with daylight from above and behind. The hemisphere, which was also equipped with a central air tube for simulation of wind on the head in flight, could be rotated around all three orthogonal axes and thus simulate pitch, roll and yaw deviations. *c*, Response of the left DNC to simulated clockwise and anticlockwise rolls away from (upper two records) and towards (lower record) the normal flying position. The sketches show the initial and final positions of the horizon, and the arrows the direction of its rotation. Only clockwise rolls away from the normal position evoke graded responses. Upper traces: intracellular recording, scale bars 50 mV, 200 ms; lower traces: roll monitor, vertical scale bar 75°. *d*, Response of same unit as in *c* to three identical frontal wind stimuli (onset at arrows) during maintained simulated visual rolls to various positions, as shown in the sketches. Calibrations as in *c*. Non-preferred orientations of the visual world inhibit the response to wind. *e*, Response of a DNI (centre trace, intracellular recording, scale bars 5 mv, 200 ms) to a visually simulated roll (lower trace, vertical scale bar 75°) and to simultaneous ON/OFF stimulation of the ipsilateral ocellus by means of a separate light pipe (upper trace, light at 565 nm modulated by 1 $\log_{10}$ unit, upward going = ON, duty cycle 200 ms). Ocellar OFF stimuli evoke only single spikes when presented alone (asterisk). These summate with the response induced by visually signalled roll. Ocellar ON stimuli are functionally incompatible with the visual information, as they imply a roll in the opposite direction; they strongly inhibit the visual response, which otherwise would consist of a long phasic-tonic burst, as in the middle record of *c*.

Table 1 Excitatory input characteristics of deviation detector neurones

	DNI	DNM	DNC
Ocellus producing reliable* excitation with OFF stimulation	Ipsilateral	Medial	Contralateral
Most effective visually simulated deviation (that is, via compound eyes)	Roll ipsilateral Pitch down Yaw ipsilateral	Pitch down	Roll contralateral (Pitch down)† Yaw contralateral
Most effective wind direction corresponds to	Yaw ipsilateral	Pitch down	Yaw contralateral

Data were derived from 60–100 experiments on each cell.
* DNI received additionally weak input from the medial ocellus, and DNM from both ipsi- and contralateral ocelli. In a fraction of the population, these weak inputs can evoke spikes.
† Weak response.

will also be excited by selective darkening of the right ocellus, which would in nature be darkened by such a roll[15].

The response properties of a deviation-detecting neurone are not, however, shaped simply by summation of excitation from three sensory sources. Mutual inhibition between the different sensory inputs is also important, and prevents a response if there is a conflict in information content. For example, Fig. 1*d* shows that the position of the visual world can alter the response of the cell to a constant wind stimulus. If the horizon is rolled to a 'visually preferred' position (Fig. 1*d*, top records), indicative of a specific deviation, and held there, the response to a frontal wind stimulus is strong (here 34 action potentials). If the horizon is held in a near-horizontal position (Fig. 1*d*, middle records), the same wind stimulus produces only a modest excitation (7 action potentials). Finally, if the horizon is rolled to a 'visually antipreferred' position, one which does not represent a deviation of interest to this cell, its response to the identical wind stimulus is virtually eliminated (1 action potential). Similarly, Fig. 1*e* shows that the ocellar input can inhibit the response to compound eye input. Darkening of the left ocellus produces an action potential in the left DNI, which responds visually to an anticlockwise roll. However, selective illumination of the same ocellus via a light pipe strongly inhibits the response of the neurone to an otherwise effective visual roll stimulus. Inhibition of the wind input by ocellar input[8] and inhibition of the compound eye input by wind input can be demonstrated in similar ways. These inhibitory relations reflect the relative probability of error for a conflict occurring in natural conditions (for example, turbulence could affect the wind hairs without producing a course deviation; the eyes would experience no change in stimulus, and the two inputs to the interneurone would convey conflicting information were it not for the inhibition). Taken together, these interactions ensure that the firing of any of these neurones is a reliable indication of a specific and well-defined deviation from course. Each neurone responds optimally to that specific combination of sensory stimuli which would impinge on the compound eyes, ocelli and wind hairs during a specific deviation. The units are formally multimodal, but we feel that this is not a useful description; the feature detected by these neurones, their 'emergent modality', is course deviation.

The cells central to the transformation of the firing of these deviation detectors into appropriate steering manoeuvres are a population of thoracic interneurones[9] that have three important characteristics[16] (see Fig. 2*e*): (1) they are postsynaptic to specific descending deviation detectors, (2) they are powerfully presynaptic to specific flight motoneurones and (3) they receive

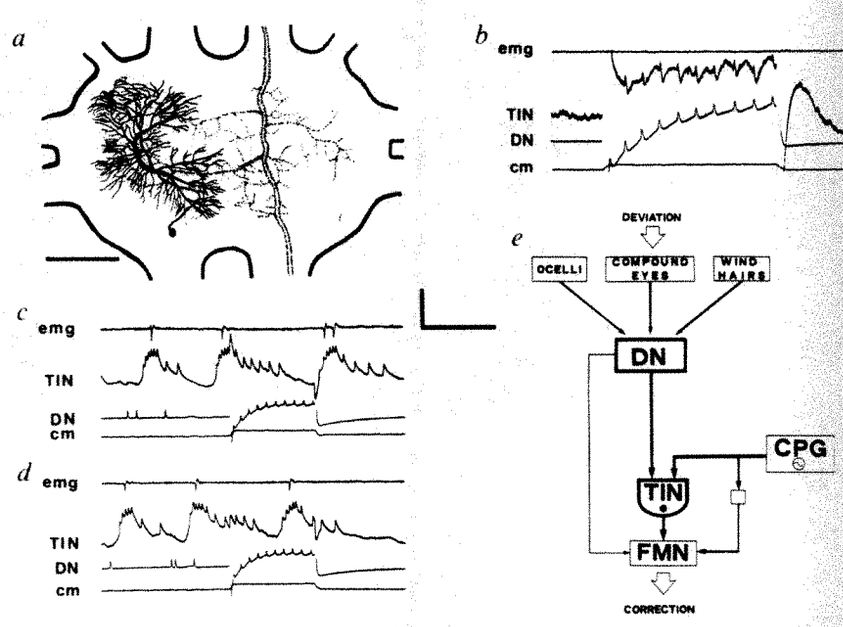

Fig. 2 Flow of information from the deviation detector neurones (DN) to the flight motoneurones (FMN) is gated in the thoracic interneurones (TIN) by summation with a phasic signal derived from the central pattern generator for flight (CPG). *a*, Presynaptic DNM (dotted) and representative postsynaptic TIN (solid) in mesothoracic ganglion (scale bar, 300 μm). *b*, Simultaneous intracellular recordings in a non-flying locust (scale bars 2 mV and 50 mV, respectively, 50 ms) from the TIN and DN shown in *a*, and an extracellular recording from the dorsal longitudinal depressor muscle ('emg') which serves as a monitor of flight activity. A depolarizing current of 10 nA ('cm') injected into DN evokes 10 action potentials, which in turn evoke small 1 : 1 excitatory postsynaptic potentials (e.p.s.ps) in the TIN. (The small high-frequency deflections on the TIN trace are artefacts caused by capacitative coupling between the two electrodes. The input bridges of both recording amplifiers are balanced, but the high current necessary to evoke a brisk burst of action potentials from an axon penetration results in a sizeable stimulus artefact.) *c*, *d*, Same experiment as *b*, but during flight motor output, indicated on the emg trace by periodic depressor muscle potentials. Scale bars 20 mV (TIN), 100 mV (DN) and 100 ms. The TIN receives strong synaptic drive from the CPG, depolarizing in the depressor phase. Note that in *c* and *d* the current pulses come at different points in the wing-beat cycle. During the depressor phase, e.p.s.ps evoked by spikes in the DN increase the number of action potentials in the depolarized TIN by ~50%, which in turn influences the postsynaptic FMN (not shown). Visual stimuli can cause a spike rate in the DN 50% greater than that induced here by current injection, so that this figure underplays the potential effect. During the elevator phase, the same DN activity does not evoke spikes in the TIN, and thus has no effect on the FMN postsynaptic to that cell. *e*, Summary diagram indicating the main relationships in the circuitry discussed here. Thickness of arrows is roughly proportional to the relative strength of the interaction. The TIN population is symbolized as an AND-gate, reflecting its role. CPG drive reaches the FMNs not only via the TINs, but also by other interneurones which do not receive DN input.

Table 2 Synonomy of the deviation detector neurones

Fast ipsilateral, Fast ipsilateral (medial)	Fast contralateral	Fast medial	9

Deviation detector neurones have been mentioned under different names by previous authors; all used *Schistocerca* rather than *Locusta*, but we can detect no differences. Their descriptions were based on partial dye fills (for example, thoracic ganglia but not the brain, or vice versa) and either incomplete physiological data or none at all. The only complete structure previously given[8] is actually derived from two separate units, one filled in the brain and one in the thoracic ganglia. Normally, the oldest nomenclature would be adopted (in this case the $O_{1...n}$ system[28]). This is no longer practical, as is evident from the table. Abbreviations: $O_{2,3,...}$, ocellar interneurone 2, 3, . . .; ip 1, ipsilateral 3rd-order ocellar neurone; cl 1, contralateral 3rd-order ocellar neurone; i.o., ipsilateral ocellar neurone; c.o., contralateral ocellar neurone; VIP, ventral nerve cord unit, ipsilateral to its soma, protocerebral soma; VCP, ventral nerve cord unit, contralateral to its soma, protocerebral soma.

rhythmically alternating excitatory and inhibitory drive from elements of the flight central pattern generator[13], at phase angles characteristic for each interneurone. One such thoracic interneurone is shown in Fig. 2*a*. In a non-flying animal, the firing of the presynaptic DNM evokes only subthreshold synaptic potentials in this thoracic interneurone (Fig. 2*b*). Postsynaptic flight motoneurones are consequently not affected and no behaviour results. However, in a flying animal the flight central pattern generator is operative and delivers rhythmic drive to the thoracic interneurones. If the deviation detector is now fired (Fig. 2*c*, *d*), the synaptic input it evokes in the thoracic interneurone summates with central pattern generator drive, causing the interneurone to fire an increased number of action potentials. This augmentation occurs only when the drive is depolarizing (Fig. 2*c*, *d*). Because of the rhythmic nature of the depolarizing and hyperpolarizing potentials evoked by the flight central pattern generator in the thoracic interneurone, the tonic deviation signal is transformed into phasic activity of the premotor interneurones. Sensory information is gated at the level of the thoracic interneurone. The appropriate postsynaptic flight motoneurones will consequently receive additional drive, phase-coupled with the wing-beat cycle, for the duration of the descending deviation signal. This additional phase-coupled motor drive can either alter the phase of firing of one of a pair of homologous bilateral motoneurones, or alter the number of action potentials in the discharge of affected motoneurones, or even recruit an otherwise silent motoneurone. These comprise the mechanisms which have been shown to operate during steering behaviour by intact locusts[17-20]. All the flight motoneurones and the premotor interneurones are spiking cells with all-or-none threshold characteristics, clearly a prerequisite for this mechanism. We describe elsewhere[16] circuitry in which the CPG-evoked depolarizations in the premotor interneurones summate with inhibitory postsynaptic potentials derived from the deviation detector neurones, rather than with their excitatory postsynaptic potentials, but which has similar effects on the firing pattern of the motoneurones. That summation of inputs to spiking premotor interneurones could lead to gating of the signal to motoneurones has been postulated previously[21], but not demonstrated.

The deviation detector neurones also make direct connections with the flight motoneurones[8,9]. We have shown elsewhere[16] that these connections produce much smaller postsynaptic potentials than those mediated by premotor interneurones. This is understandable in view of the need to avoid flight muscle contraction when the animal is not flying; the direct input to the flight motoneurone must be small enough to avoid firing it, even though the motoneurone receives an almost continuous barrage of sensory excitatory postsynaptic potentials from other sources. In flight, however, these direct postsynaptic potentials are also subject to a similar gating process by the flight central pattern generator, which drives the motoneurones directly[13] as well as the premotor interneurones.

Thus, at the thoracic level, a two-stage gating process ensures that the intrinsically phase-independent information from the deviation detectors: (1) elicits a response in the flight motoneurones only when the flight central pattern generator is operative, that is, in the behavioural context of flight, (2) is phase coupled, that is, is transformed into a phasic signal modulated at wing-beat frequency and (3) is automatically applied to the appropriate group of flight motoneurones which are active at the time of arrival of the signal, obviating the need for any further decision-making in the brief interval between stimulus and response.

The complete steering behaviour of the animal involves not only the modulation of wing beat treated here, but also movements of head, abdomen and hind legs[11,22-24]. It remains unclear whether the circuitry described here participates in these elements. However, we have evidence that the information brought to the thoracic ganglia by the other deviation-sensitive interneurones is processed in the same way as described above. Furthermore, the circuit principles documented here seem to be generally applicable and significant. In vertebrates, for example, locomotor control involves descending pathways from projection areas in the brain to segmental motor centres in the spinal cord and thence to spinal motoneurones[25]. Moreover, a gating process has been postulated and ascribed to the level of the segmental interneurones[26,27]. This scheme is comparable in detail to the circuitry documented here for the locust (see Fig. 2*e*). Indeed, we expect that similar principles of neuronal organization will be found in all animals that need to integrate a rhythmic motor output with non-phase-locked exteroceptive information, a need that occurs in most forms of locomotion.

We thank P. Wehrli for technical assistance and W. W. Stewart for a gift of Lucifer yellow. This research was supported by the Schweizerischer Nationalfonds.

Neuronal growth, atrophy and death in a sexually dimorphic song nucleus in the zebra finch brain

Masakazu Konishi & Eugene Akutagawa

Division of Biology, California Institute of Technology, Pasadena, California 91125, USA

The song control nuclei of the zebra finch brain contain more neurones of larger diameter in the male than in the female[1]. This sexual dimorphism is thought to result from differential growth of neurones in the two sexes[2–4]. Using neurohistological techniques and radioactive tracers, we have studied the development of several forebrain nuclei involved in the control of song and find that the dimorphism arises from neuronal atrophy and death in the female brain as well as from an increase in cell-body size and afferent terminals from other forebrain nuclei in the male. Although the timing of these events varies from nucleus to nucleus, the sequence is essentially similar in all of them except area X. Here we describe the events in one of these nuclei, the robust nucleus of archistriatum (RA), as an example.

Zebra finches breed well in captivity and provide chicks of known ages all year round. Neurone counts were made on sections stained with cresyl violet and the neuronal connections from HVc (ventral nucleus of hyperstriatum caudal division) to RA were traced by conventional autoradiographical methods. The distinct boundaries of RA are convenient for the measurement of various cytoarchitectonic and cellular properties at all stages of development. For the measurement of RA volume, the boundaries of the nucleus in every third section were drawn with a Zeiss camera lucida onto a sheet of paper and the area within the boundaries was calculated by a computer-aided planimetric method. Because of the error involved in the sampling method, the average between the minimum and maximum estimates of the volume was chosen as the best estimate. The same planimetric method was used for the calculation of soma area from perikaryal outline tracings. For the purpose of this report, the neurone density and number were determined only for a few selected age groups and are not shown in graphical form. Sections having the largest cross-sectional areas of RA were photographed *in toto* and neurones were counted on enlarged prints. The number of neurones counted in each section divided by the volume of the section gave an estimate of the neurone density, which did not differ by more than 10% from that obtained by counting the number of neurones in random sample grids under a microscope. The total number of neurones in RA was estimated by multiplying the neurone density by the RA volume.

The cytoarchitecture of RA reveals few differences between the sexes soon after hatching but later begins to diverge towards growth in the male and atrophy in the female (Figs 1, 2). The growth in RA volume in the male is mainly the result of changes in the size and density of neuronal cell bodies; the somata become larger and less densely packed. The estimate of neurone number at day 15 ranges from 9,100 to 14,900 (median = 11,300) and from 9,200 to 14,900 (median = 9,600), respectively, for the male and the female. These numbers should be compared with those of adult birds which range from 9,300 to 14,300 (median = 13,600) for the male and from 2,400 to 3,700 (median = 2,900) for the female. Thus, the female RA loses about two-thirds of its neurones by the adult stage, whereas the male RA retains essentially the same range of neurone numbers. The sharp decline of RA volume in the female after day 30 results from both a decrease in the neurone number and size on one hand and an increase in the neurone density on the other; the cells are fewer, smaller and more densely packed. These small cells were identified as neurones by retrograde labelling from the target areas of RA neurones[3].

During their development RA neurones are mainly innervated by axons from HVc and to a lesser extent by axons from MAN

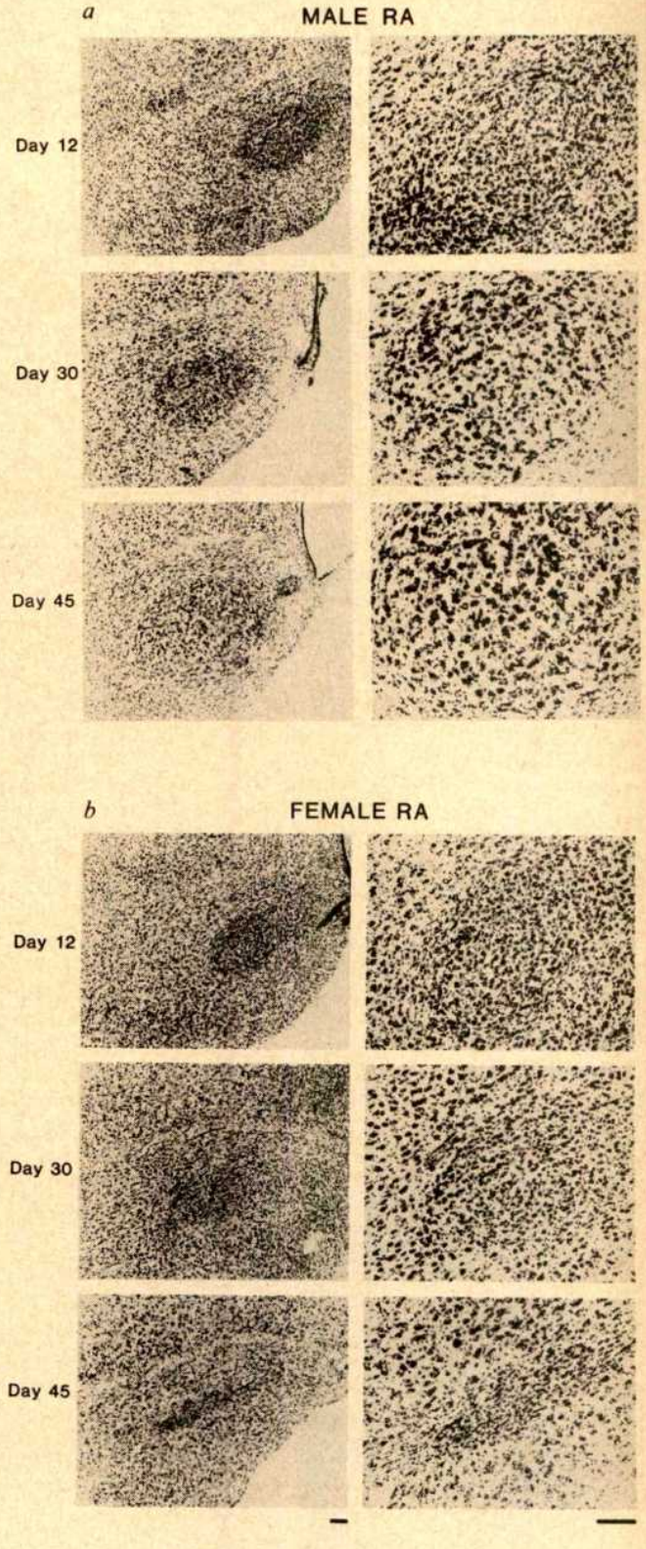

Fig. 1 Contrasting developmental stages of RA in the two sexes. At day 12 after hatching, the male (*a*) and female (*b*) RAs are similar in size; at day 30, the cell bodies of neurones are smaller in the female RA than in the male RA. By day 45 the female RA has shrunk, whereas the male RA has grown both in volume and soma size. For histological examination of brains, birds were anaesthetized with Equithesin, perfused with saline and then 10% formalin. After overnight immersion in 20% sucrose solution, brains were cut in 30 μm thickness with a freezing microtome, and these sections were stained with cresyl violet. Each photomicrograph shows the largest cross-sectional area of RA for a given age in a parasagittal section. Low- and high-magnification pictures of the same section are shown side by side. Scale bars, 100 μm.

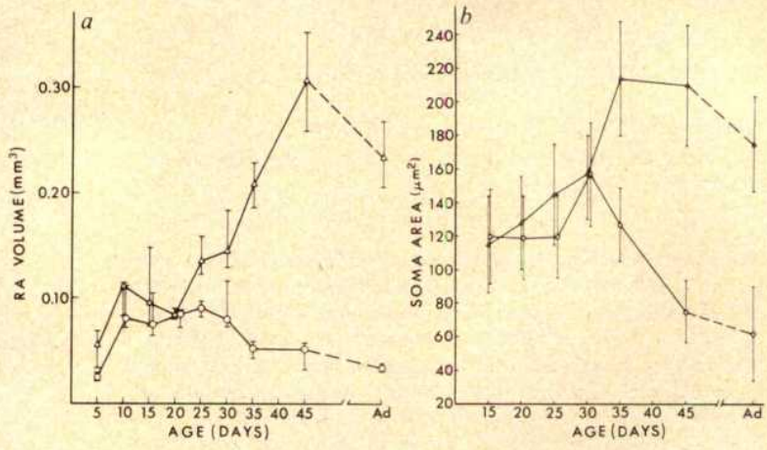

Fig. 2 Quantitative comparison of architectonic and neuronal changes (male, △; female, ○). Dashed lines indicate unsampled age intervals. *a*, Changes in RA volume. For each age and sex group, the median and range of the RA volume of five birds are plotted as a function of age. From days 5 to 20 after hatching, RA grows to about an equal volume in both sexes. Thereafter, the male RA continues to grow with a steep increase in growth rate at about day 30, although there is a temporary dip in the growth curve at about day 20. The volume of the female RA, on the other hand, remains almost constant from day 10 to day 30 when a sharp decline begins. *b*, Changes in neurone size. Each of five birds used for each age and sex group provided a sample of 50 neurones for the computation of a mean and standard deviation. The graph plots the means of the five means and standard deviations as a function of age. In the male, the mean cross-sectional area of RA neurones increases steadily, reaching a plateau at about day 35. In the female, the mean soma area remains more or less constant until about day 30 when it begins to decrease rapidly.

(magnocellular nucleus of anterior neostriatum). The time course and pattern of innervation also show differences between the sexes. An injection of tritiated proline in HVc and its immediate vicinity in 15–25-day-old chicks of either sex results in an accumulation of radioactivity (grains) around RA (Fig. 3), while control injections outside HVc and its adjoining areas do not produce this pattern of grain distribution. Furthermore, when radioactivity accumulates within the boundaries of RA as in males older than 35 days, the ring of grain density around the nucleus disappears (Fig. 3). Whatever the identity of the ring may be, labelling within the boundaries of RA indicates innervation of its neurones. Thus, the male RA appears to remain uninnervated until about day 30 when it suddenly becomes innervated. This stage corresponds to the beginning of the steep increase in RA volume. The soma density begins to decrease rapidly at about this age, presumably because the accommodation of the incoming afferent fibres results in an increase in the distance between RA neurones. The female RA appears to remain largely uninnervated, although sparse connections between HVc and RA may present in the adult[3].

The above findings indicate that cell atrophy and death constitute a normal process of sexual differentiation in the brain. In theory, differences in neurone number and size in sexually dimorphic areas of the brain may result from differential proliferation, growth, atrophy, death or migration[5,6]. However, we did not consider cell atrophy and death in our earlier work on the zebra finch. Consequently, we did not consider that early oestrogen may masculinize the female RA by preventing cell death[2–4]. As to cell migration, it is very unlikely that large neurones emigrate from the female RA and small neurones migrate into it. Neurogenesis is reported to occur in the adult zebra finch brain[7]. Because neurogenesis in the adult is generally not restricted either to the song-control system or to one sex, it is perhaps not a major factor in the sexual differentiation of the song-control system. The presence in the male and the absence in the female of neuronal connections between HVc and RA suggest a causal relationship between innervation and neuronal growth: the afferent innervation of RA may be essential for the growth of its neurones; alternately, the growth of RA neurones may induce innervation by HVc fibres. How oestrogen mediates one of these processes is not known.

The origin of brain sex differences by neuronal growth in the male and cell death in the female is not unique to the zebra finch, for all well-documented cases of brain sex differences appear to involve cell death in the female. Recent evidence indicates that differences in neurone populations between the sexes in the preoptic area and the bulbocavernosus nucleus of mammals involve growth of neurones in the male and cell death in the female[8–11]. Cell death is a common phenomenon in the development of the nervous system; however, the role of cell death in development varies from system to system[12]. For sexually dimorphic systems the significance of cell death is clear; neurones disappear in the female system because females do not need to exhibit the behaviour controlled by the relevant neurones. Why are the neurones that are destined to die produced in the first place? It could be that a genetic programme uses the same set of genes for a homologous neural circuit in both sexes and an epigenetic process determines the fate of the circuit in the two sexes.

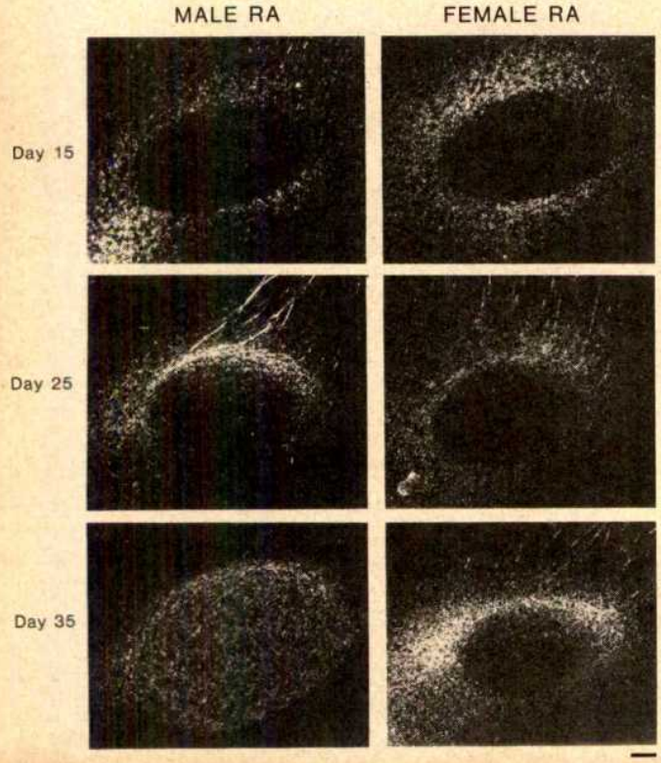

Fig. 3 Sex differences in innervation of RA. A glass pipette, 15 μm in tip diameter, was used for the iontophoretic injection of tritiated proline into HVc. The survival time after the tracer injection was 3 days. Brain sections for autoradiography were exposed for 30 days at 4 °C. Dark-field autoradiographs of RA show the distribution of silver grains for three different ages. These patterns of grain distribution appear when tritiated proline is injected in HVc and its immediate vicinity. The unlabelled oval area is RA. At day 15 both male and female RA fail to accumulate radioactivity no matter how large the injection area may be. At day 25 the male RA shows some labelling within its boundaries and is completely labelled by day 35. Note the absence of labelling outside the boundaries of RA. In contrast, the female RA remains mostly unlabelled throughout its development including the adult stage. These changes in labelling indicate when and to what extent RA becomes differently innervated in the two sexes. Scale bar, 100 μm.

We thank Drs C. E. Carr and P. Patterson for reading the manuscript and Chris Yo for assistance. This work was supported in part by a grant from the Whitehall Foundation.

Changes of free calcium levels with stages of the cell division cycle

Martin Poenie*, Janet Alderton†, Roger Y. Tsien* & Richard A. Steinhardt†

* Departments of Physiology-Anatomy and † Zoology, University of California, Berkeley, California 94720, USA

Although the regulation of events in the cell division cycle by calcium or other cations has been the subject of much interest and speculation[1-10], experimental studies have been hampered by the difficulty of measuring submicromolar intracellular free calcium concentrations ($[Ca^{2+}]_i$) over an entire cell cycle. We now describe experiments using a new fluorescent calcium chelator, fura-2 (see Fig. 1c for structure), for continuous measurement of $[Ca^{2+}]_i$ from fertilization through the first cleavage of individual eggs of the sea urchin *Lytechinus pictus*. We also show for comparison the results of parthenogenetic activation by ammonia. In addition to the known transient rise of $[Ca^{2+}]_i$ at fertilization, further peaks are now revealed during pronuclear migration, nuclear envelope breakdown, the metaphase/anaphase transition and cleavage. Parthenogenetic activation by ammonia also elicits a sustained rise starting at nuclear envelope breakdown.

Fura-2 is a fluorescent tetracarboxylate chelator that exhibits a spectral shift in excitation maxima on binding calcium[11]. Increasing free Ca^{2+} increases the fluorescence excited by 350 nm light and decreases the fluorescence from 385 nm excitation. The ratio of fluorescence excited by 350 nm to that excited by 385 nm is a measure of $[Ca^{2+}]_i$ in which the uncertainties in dye concentration, cell thickness and absolute optical efficiency of the instrument are cancelled. We measured 350/385-nm ratios from single eggs, injected with fura-2, on a fluorescence microscope that had rapidly alternating excitation wavelengths[12]. Ratios were calibrated in terms of $[Ca^{2+}]_i$ by comparison with dye samples of known $[Ca^{2+}]_i$. Figure 1*a* shows the fluorescence signal during fertilization, recorded simultaneously at 350 nm and 385 nm excitation wavelengths. Shortly after addition of sperm, the fluorescence from 385 nm excitation fell dramatically whereas the fluorescence from 350 nm increased. Changes in the 350/385-nm fluorescence ratio are shown in Fig. 1*b*, while Fig. 1*c* shows the actual $[Ca^{2+}]_i$ after dye calibration. From these records we calculated that resting $[Ca^{2+}]_i$ averages 144 ± 10.3 nM (mean ± s.e.m., $n = 11$), with extremes between 70 and 250 nM (data not shown). The fertilization transient takes ~12 s from beginning to peak and rises to an average of 1.95 ± 0.16 μM ($n = 11$). Levels as high as 3.5 μM were observed, although such eggs were usually polyspermic. These values are close to those estimated previously from fertilization experiments with aequorin-loaded eggs[13]. The fertilization transient lasts ~5 min, during which time the sperm is incorporated into the egg and the sperm nucleus is transformed into the male pronucleus[14,15].

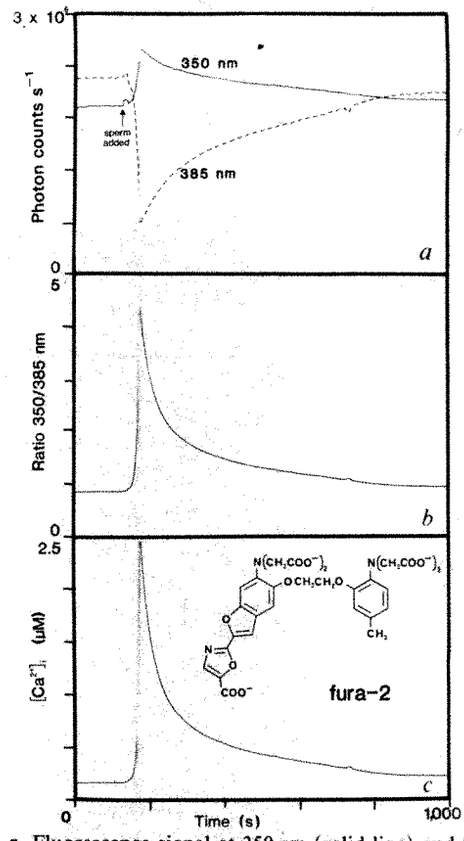

Fig. 1 *a*, Fluorescence signal at 350 nm (solid line) and 385 nm (dotted line) excitation during fertilization, ending just before the onset of a second (pronuclear migration) peak. The addition of sperm (at the arrow) caused a small artefact which can be seen to cancel out when ratios are taken (see *b*). Shortly after the addition of sperm, the fluorescence at 385 nm decreases dramatically (broken line) whereas the signal increases at 350 nM (solid line). *b*, Fluorescence ratio (R), obtained by dividing the fluorescence values at 350 nm by those at 385 nm. This ratio changes in the same direction as $[Ca^{2+}]_i$ and can be used to calculate $[Ca^{2+}]_i$ from the equation[11] $K(R-R_0)/(R_s-R) = [Ca]$, where R_0 is the ratio at 0 calcium and R_s is the ratio at saturating calcium. K represents $K_d(F_0/F_s)$, where K_d is the effective dissociation constant for fura-2 in the appropriate conditions, F_0 is the fluorescence at 385 nm in 0 Ca and F_s is the fluorescence at 385 nm in saturating calcium solutions. R_0 and R_s were obtained from droplets of fura-2 reference standards containing 50 μM fura-2, 155 mM KCl, 25 mM NaCl, 100 mM MOPS neutralized with KOH to *p*H 7.02 and either 10 mM K_2H_2-EGTA or 1 mM $CaCl_2$. The effective dissociation constant for fura-2 was determined to be 7.74×10^{-7} M by cuvette titration of 5 μM fura-2 in the above KCl/NaCl/MOPS medium with 10 mM EGTA buffers. The necessary dissociation constants for Ca-EGTA buffers were measured at 18°C in 225 mM KCl and 25 mM NaCl (ref. 11). *c*, Actual $[Ca^{2+}]_i$ values derived from the ratio in *b* after applying the calculation shown above. The inset shows the structure of fura-2.

Methods. *Lytechinus pictus* eggs were microinjected with a solution of 40 mM fura-2, 5 mM $CaCl_2$ and 0.66 M potassium gluconate (the injection solution was prepared by hydrolysing the fura-2 pentaethyl ester in 1 M KOH and neutralizing the hydrolysate with D-gluconic acid lactone). Typical dye loadings were 50-200 μM based on comparison with 100-μm droplets of dye standards. Excitation light was provided by two Spex Industries monochromators preset at 350 nm and 385 nm and selected in rapid alternation (15 Hz) by a rotating chopper mirror. These wavelengths were displaced from the true excitation peaks to avoid the transmission cutoff of glass optics at lower wavelengths. Emitted light was collected through a 500-530-nm interference filter and photon-counted in synchrony with the chopper so that the signals from the two excitation wavelengths were stored in separate memories of a Spex Datamate microcomputer. Monochromator slits of 0.25 mm were used, giving a 0.9-nm bandpass, and an attenuator screen further reduced the excitation intensity fivefold. Dye bleaching was usually undetectable, yet the photometer count rate was $1\text{-}2 \times 10^6$ photon counts per s; uninjected eggs gave $0.5\text{-}1.5 \times 10^4$ counts per s. All experiments were at 18 °C.

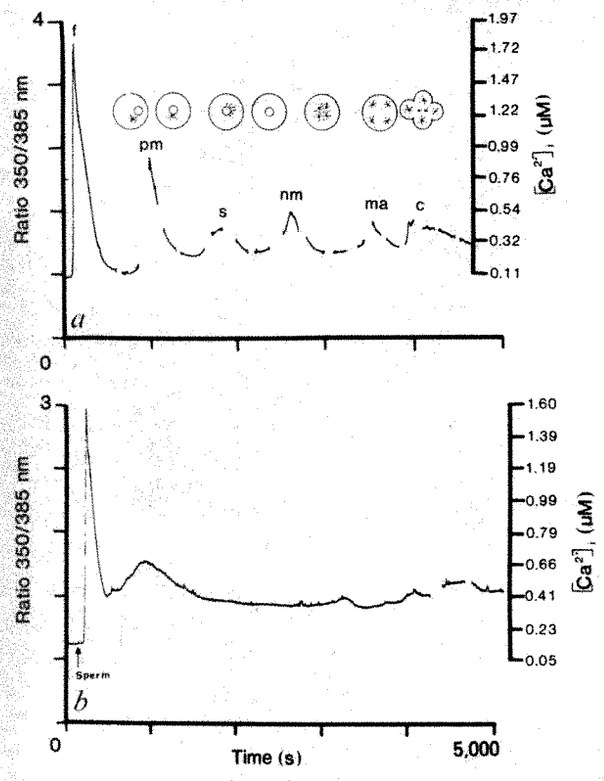

Fig. 2 Two complete records from fertilization to the first cell division. ***a*** Shows clearly the pattern of calcium fluctuations during the cell cycle seen in our records. Peaks in this record are especially prominent, as the post-fertilization baseline $[Ca^{2+}]_i$ is unusually low. However, the peak calcium levels still attain normal values, similar to those of the corresponding periods of *b*. The breaks in the trace were periods in which the trace was interrupted in order to take transmitted light photographs (not shown) to record any corresponding morphological events: f, fertilization peak; pm, pronuclear migration peak; s, streak stage peak; nm, nuclear membrane breakdown peak; ma, metaphase/anaphase peak; c, cleavage peak. This example happened to be polyspermic, and the first division resulted in four cells. ***b*** Is a typical trace where the post-fertilization baseline is higher. This egg underwent normal cleavage between the first and second breaks at the end of the record.

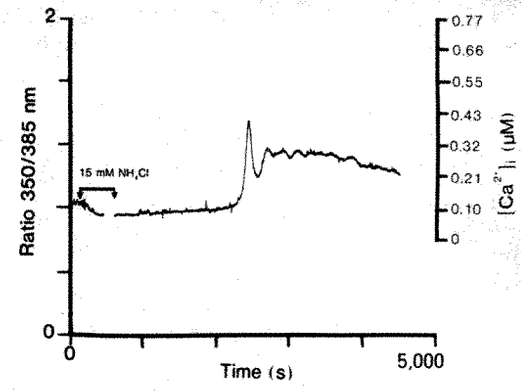

Fig. 3 A typical example of an egg activated by a 10-min pulse (arrows) of sea water containing 15 mM ammonium chloride, *p*H 8.0. From previous measurements[21], intracellular *p*H would be expected to rise from 6.9 towards 7.4–7.6 during ammonia exposure and to remain permanently above 7.3 even after ammonia withdrawal. Calcium levels can be seen to fall slightly with the addition of ammonia, but to rise sharply at 40 min after the addition. These results are typical of three similar experiments. Further experiments (not shown) give similar results even when ammonia is left in continuously or when external calcium is reduced to 10^{-7} M.

The low illumination intensities required with fura-2 and its apparent low toxicity allowed continuous measurement of calcium throughout the cell cycle. Embryos routinely cleaved at least three times (see Fig. 1 legend for details). Figure 2 shows two examples of continuous records obtained from fertilization to first cleavage. Cyclical changes in $[Ca^{2+}]_i$ coincide with specific events of embryo development and the cell division cycle. Figure 2*a* shows particularly well-defined $[Ca^{2+}]_i$ peaks corresponding to different stages of the cell cycle. In the most typical records (see Fig. 2*b*), peaks reach values similar to those in Fig. 2*a* but appear less striking because they rise from a permanently elevated plateau level of $[Ca^{2+}]_i$. Both records reveal that at 10–12 min after fertilization, a second, surprisingly large, increase in $[Ca^{2+}]_i$ occurs. Photographs taken during the breaks in Fig. 2*a*, as well as many observations during other experiments, indicate that this peak occurs during pronuclear migration. The average peak $[Ca^{2+}]_i$, 665 ± 51 nM ($n = 8$), is well above the mean post-fertilization baseline of 277 ± 28 nM ($n = 8$). EGTA-induced reduction of the external calcium concentration to 10^{-7} M did not affect this peak or subsequent peaks, suggesting that the increases in calcium result from release from internal stores (data not shown).

In 10–20% of the embryos (including that of Fig. 2*a*), we observed another calcium peak associated with the streak stage (the period of pole separation and DNA synthesis)[16]. This transient was seen in both polyspermic and monospermic embryos.

Another elevation of $[Ca^{2+}]_i$ occurred 50–60 min after fertilization, with an average peak value of 404 ± 20 nM ($n = 8$). Photographs indicate that the increase in $[Ca^{2+}]_i$ occurs close to or during nuclear envelope breakdown. This peak in free calcium may explain earlier findings of Bennet and Mazia[17] in which unfertilized eggs that had been fused with fertilized embryos underwent cortical granule breakdown in the unfertilized half when the fertilized half began mitosis. The trigger for Ca^{2+} at nuclear envelope breakdown may have triggered the release of Ca^{2+} stores in the unfertilized half.

A fourth peak was observed ~70 min after fertilization, with a mean value of 410 ± 10 nM ($n = 6$). Photographs and visual checks suggest that this peak occurs during the metaphase/anaphase transition, although precise timing is difficult because we cannot resolve the actual chromosome movements. However, in Fig. 2*a*, the spindle was newly formed before the peak, and spindle elongation, corresponding to late anaphase, did not occur until after the peak, thus indicating that the metaphase/anaphase transition occurred during the period of the peak. Although other investigators have suggested that calcium may be involved in the metaphase/anaphase transition, until now there has been no evidence that an increase in $[Ca^{2+}]_i$ actually takes place. Izant has reported that injections of calcium buffered at 1 μM or 50 nM free calcium, respectively, shorten or lengthen the duration of metaphase[4]. Wolniak *et al.* reported a decrease in chlortetracycline staining during metaphase, suggesting that a release of calcium stores occurs at the onset of anaphase[7].

Finally, we observed an increase in $[Ca^{2+}]_i$ associated with cleavage. We found that calcium rises to a mean value of 412 ± 34 nM ($n = 7$); this increase slightly precedes and occurs in conjunction with the developing cleavage furrow. The notion that calcium may regulate the activity of the contractile ring has been suggested by several investigators using injection of calcium buffers or ionophore A23187 (refs 1, 2, 6), although attempts to measure a change with aequorin have been equivocal[1,18]. On the other hand, $[Ca^{2+}]_i$ measurement in *Xenopus* embryos using ion-selective microelectrodes consistently failed to show evidence of cell-cycle-related fluctuations in calcium[19]; this was perhaps a result of species differences or localization of calcium rises that always missed the electrode tip.

The general elevation of baseline $[Ca^{2+}]_i$ and upward fluctuations during the cell cycle are not the only ionic events that follow fertilization of sea urchin eggs. A rise in internal *p*H, normally dependent on external Na^+, is known to be necessary for development[20,21]. The addition of ammonia to sea water, which artificially elevates the internal *p*H, induces many of the

events of the cell cycle, such as DNA synthesis, chromosome condensation and nuclear envelope breakdown[22]. We hypothesized that if calcium is pertinent to these cell-cycle events, ammonia might affect $[Ca^{2+}]_i$; however, at first sight this seems unlikely as ammonia does not cause a cortical reaction or any obvious change in NADP/NAD ratios, both of which are calcium-dependent consequences of fertilization[23,24]. We measured $[Ca^{2+}]_i$ in ammonia-treated eggs (Fig. 3) and found that during the first 40 min after addition of ammonia, $[Ca^{2+}]_i$ either decreased slightly or did not change. A decrease in $[Ca^{2+}]_i$ would be interesting in light of the finding that the activity of the calcium-sequestering system is enhanced by elevated pH[25]. However, at ~40–55 min, $[Ca^{2+}]_i$ rose to levels characteristic of fertilized eggs entering mitosis (350–400 nM) and remained elevated thereafter. Inspection revealed that the nuclear envelope broke down at 60–70 min, shortly after the increase in $[Ca^{2+}]_i$. Similar results were obtained even if external calcium was lowered to 10^{-7} M, indicating that ammonia can eventually reset the intracellular calcium levels even in the absence of external calcium. This finding requires a revision of the conclusions reached by Zucker *et al.* on the action of ammonia on the nuclear envelope[26]. Using aequorin, they were unable to detect these low calcium concentrations during the ammonia treatment and so concluded that ammonia exerted its effect through alkalinization alone. Although ammonia does raise $[Ca^{2+}]_i$ after 40–55 min, earlier events, such as the acceleration of protein synthesis which starts 25 min after ammonia addition, must be pH responses not mediated by calcium[27].

The observed correlation between mitotic events and changes in $[Ca^{2+}]_i$ does not prove that these changes are required for the observed events. The causal relationship between ionic and mitotic events will be clarified when a means becomes available for controlling $[Ca^{2+}]_i$ at given times.

The study of retrovirus-induced leukaemias in mice is a powerful tool for the elucidation of the normal regulation of the haematopoietic system. The acute murine spleen focus-forming viruses (SFFV) can be classified according to the haematopoietic lineage on which they exert their effects in the adult mouse. Here we report a new SFFV isolate, the AF-1 virus, with the novel ability to transform cells of the mononuclear phagocyte lineage. The virus was isolated from sarcomas that were induced on passage of a cloned Friend helper virus (F-MuLV, 643/22F)[1] in newborn BALB/c mice. We have cloned the transforming defective subunit of the AF-1 viral complex in NRK cells and isolated several subclones. Analysis of the proviral genome in two non-producer cell clones reveals that AF-1 virus contains Harvey v-*ras*-specific sequences (Fig. 1). Thus, AF-1 virus is closely related to Harvey murine sarcoma virus (Ha-MSV)[2], and is, at present, the only tool by which permanent cell lines can be obtained from mononuclear phagocytes in the mouse.

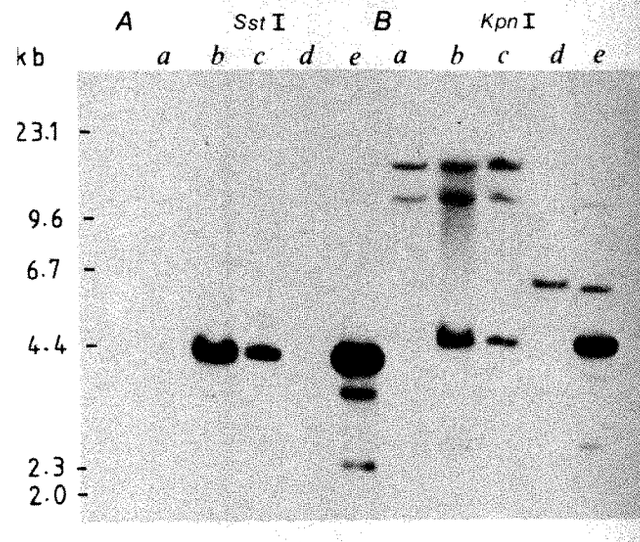

Fig. 1 Southern blots showing Ha-*ras* sequences. *Sst*I(*A*) and *Kpn*I(*B*)-digested high-relative molecular mass DNA was electrophoresed in horizontal 0.8% agarose gels and transferred to nitrocellulose filters[17]. The filters were hybridized in stringent conditions[18] to 10^6 c.p.m. ml^{-1} of ^{32}P-labelled clone BS9 of v-Ha-*ras* (specific activity 2×10^8 c.p.m. μg^{-1})[19]. Lanes *a*, NRK; *b*, AF124T; *c*, AF124TC1$_3$; *d*, 3T3; *e*, HT3. *Hin*dIII-digested *c*1857 DNA served as relative molecular mass markers: kb, kilobases. AF124T is an NRK non-producer cell clone of AF-1 virus (see text). AF124Tc13 is a subclone of AF124T. HT3 is a Ha-MSV non-producer cell clone[20].

Intravenous injection of AF-1 virus rapidly caused splenomegaly and anaemia in adult DDD (*Fv-2*^{s}) (Table 1) and B6.S mice (data not shown). DDD mice infected with AF-1 virus died within the first 25 days of the disease. C57BL/6 mice of *Fv-2*^{2} or *Fv-2*^{r} genotype were more resistant than DDD mice. C57BL/6 *Fv-2*^{r} mice survived for up to 50 days after infection. The relative resistance of C57BL/6 mice was also shown using spleen focus formation as the parameter of viral host range (T.F. *et al.*, unpublished observations).

The histological examination of AF-1 virus-infected DDD (*Fv-2*^{s}) mice revealed that the rapidly progressing spleen enlargement results from the growth of a tumour of the monocyte-macrophage/histiocyte lineage (Fig. 2). Transformed histiocytic cells were first detected in the marginal zone of the spleen 6 days after infection and then invaded the adjacent red and white pulp. At later stages these tumour cells were also found in bone marrow, lymph nodes, Peyer's patches and many parenchymal organs, but not the thymus or the brain. During the course of the disease, the cellularity of the bone marrow decreased 10-fold and at later stages the tissue recovered from the femoral cavity consisted mainly of histiocytic tumour cells. The disseminated and invasive growth of the malignant histiocytic neoplasm and the pronounced pancytopenia in AF-1 virus-infected mice were strikingly reminiscent of human malignant histiocytosis (also known as malignant medullary reticulosis), which is a systemic and fatal histiocytic tumour of both children and adults[3–6].

We also studied the effects of AF-1 virus on haematopoietic colony-forming cells (Table 1): 18 days after infection of DDD mice with AF-1 virus, no early erythroid precursor cells (burst-forming units—erythroid, BFU-E) could be detected in the bone marrow. Late erythroid precursor cells (colony-forming units—erythroid, CFU-E) were markedly decreased in the bone marrow and the spleen. The disappearance of erythroid colony-forming cells in the haematopoietic tissues of AF-1 virus-infected mice correlated well with the progressive decrease of erythroid precursor cells in the histological specimens.

The myeloid/monocytic precursor cells (CFU-C), however, were increased in the spleen of AF-1 virus-infected mice and most of them proliferated in the absence of stimulating factors. At other time points after infection with AF-1 virus, DDD (*Fv-2*^{s}) mice also showed factor-independent CFU-C in the bone marrow. In our culture system this factor-independent CFU-C formation from spleen cells of AF-1 virus-infected mice was linear, with plating densities ranging from 10^4 to 10^5 cells per dish, indicating that the factor independence is not related to the presence of factor-producing accessory cells. We obtained further evidence from studies using secondary transfer of granulocyte–macrophage and macrophage colony-forming units (CFU-GM and CFU-M) of AF-1 virus-infected mice (ref. 7 and T.F., unpublished observations). Thus, all of 17 factor-independent CFU-C from bone marrow and all of 6 factor-independent CFU-M from the spleen of DDD mice 5 days after infection with AF-1 virus continued to proliferate after transfer to liquid culture without stimulating factor for 4 months, whereas the proliferation of CFU-M transferred from uninfected controls to cultures without stimulating factors stopped after 4–6 weeks.

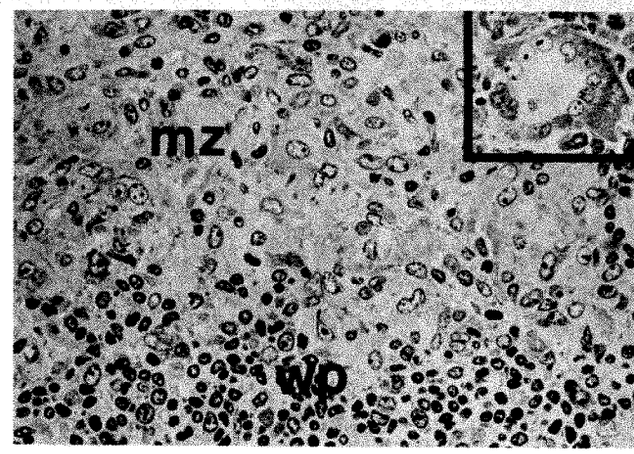

Fig. 2 Spleen of DDD mouse 10 days after infection with AF-1 virus. The normal cellular composition of the marginal zone (mz) of the white pulp (wp) is replaced by cohesively growing histiocyte-like tumour cells spreading into the red and white pulp. The tumour cells are characterized by irregular rounded, elongated, reniform or lobulated nuclei of variable size with finely dispersed chromatin and one or several prominent nucleoli. They possess abundant pale eosinophilic cytoplasm with irregular blurred cell borders. In poorly differentiated tumour cells, strong basophilic staining of the cytoplasm is seen. Bi- and multinucleated cells (inset) and mitotic figures are present. Glycol-methacrylate embedding, Giemsa stain, ×240.

Table 1 Effect of AF-1 virus on haematopoietic colony-forming cells in adult DDD mice

			Uninfected	AF-1 virus-infected
Spleen weight (mg) (mean of three measurements)			100	1,787 ± 180
Haematocrit (%)			49	34
CFU-E*	Bone marrow	None	0	0
		+Ep	180 ± 17	4 ± 1.0
	Spleen	None	0	0
		+Ep	25 ± 2.2	15 ± 1.2
BFU-E	Bone marrow	None	0	0
		+Ep	0	0
		+Wehi	0	0
		+Ep + Wehi	22 ± 3.1	0
	Spleen	None	0	0
		+Ep	0	0
		+Wehi	0	0
		+Ep + Wehi	3 ± 0.1	0.3 ± 0.2
CFU-C	Bone marrow	None	0	0
		+Wehi	104 ± 12	37 ± 4.2
	Spleen	None	0	20 ± 1.5
		+Wehi	6 ± 1.2	22 ± 0.8

Three-month-old female inbred DDD mice were injected intravenously with 6×10^3 spleen focus-forming units (SFFU) of AF-1 virus and used for the experiment 17 days after infection. AF-1 virus was rescued from 19TC13 non-producer cells with the F-MuLV clone 643/22N. This helper virus alone does not induce spleen focus formation or splenomegaly in adult mice. The technique for the assay of haematopoietic colony-forming cells has been described elsewhere[15]. Cells obtained from spleen cell suspensions or flushed out of the femoral cavity were plated at a density of 1×10^5 cells per ml in Iscove's modified Dulbecco's medium (Boehringer, Mannheim) containing 10% fetal calf serum (Flow), 0.8% methylcellulose (Fluka AG, Buchs, Switzerland), 180 μg iron-saturated human transferrin (Behringwerke, FRG) in 35-mm Petri dishes (Greiner). Where indicated, 0.5 U ml^{-1} erythropoietin (Ep) partially purified from the urine of patients with Fanconi's anaemia[15], was added. A 10% concentration of Wehi-3 conditioned medium (Wehi) was used as a source of factors (multi-CSF) that stimulate BFU-E and CFU-C formation *in vitro*[16]. Erythroid colonies of at least 20 cells were counted as CFU-E 2 days after the establishment of the culture. BFU-E form large erythroid colonies which were counted on day 9 of culture. CFU-C were recorded on the same day as BFU-E and represent the sum of macrophage, granulocytic and macrophage/granulocytic colonies.

* Data are the number of colonies per 10^5 cells plated and were obtained from three independent experiments using three mice.

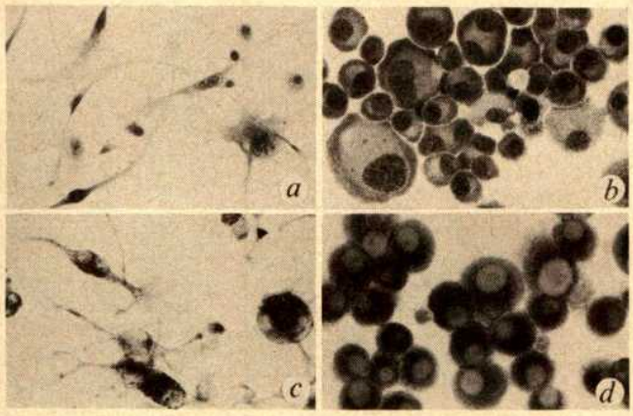

Fig. 3 HA15/A adherent (*a*, *c*) and HA15/S non-adherent (*b*, *d*) permanent cell lines obtained from spleens of DDD mice after infection with AF-1 virus. *a*, Cell line HA15/A is characterized by a pleomorphic cell type resembling macrophages. The cells obviously differ in size, cellular configuration and nuclear morphology. The cells are round or bi- and multipolar with round, oval or lobulated nuclei. The pale cytoplasm is heavily vacuolated and possesses long plump or delicately branched processes which occasionally terminate in irregular pseudopods. Multinucleated cells are present (*c*). *b*, Cell line HA15/S consists of monoblast-like cells of different size with round, chromatin-dense nuclei, strongly basophilic cytoplasm and prominent paranuclear Golgi bodies. Mono- or multinuclear polyploid cells with atypical nuclear configuration can be recognized. Both cell lines shown strong reactions with acid phosphatase (*c*, HA15/A cells) and nonspecific esterase (*d*, HA15/S cells). *a*, Giemsa, ×127; *b*, Giemsa, ×200. *c*, Acid phosphatase using naphthol AS-B1 phosphate as a substrate[6], no nuclear stain ×127. *d*, Nonspecific esterase using α-naphthyl butyrate as a substrate[5], no nuclear stain, ×200.

We found that 25% of the factor-independent AF-1 virus-infected CFU-M could be further propagated and maintained as permanent cell lines.

Cell lines were also easily established from spleen cell suspensions of AF-1 virus-infected DDD mice (cell line HA15) as early as 5 days after infection, which suggested early transformation of the target cell by AF-1 virus *in vivo*. The transformed cells proliferated readily in culture requiring neither prior passage of infected tissue *in vivo* nor a long period of tissue culture, unlike, for example, Friend leukaemia cells[8].

Shortly after establishment, the AF-1 virus-transformed cell lines mainly consisted of adherent slow-growing cells. Forced passage in culture resulted in the isolation of two sublines composed of either mainly adherent cells (HA15/A) or suspended growing cells (HA15/S). Cytologically, HA15/S cells exhibited morphological features of monoblasts and HA15/A cells resembled macrophages (Fig. 3*a*, *b*). Both sublines showed activity of nonspecific esterase and acid phosphatase (Fig. 3*c*, *d*) but no expression of Mac-1 antigen[9–11]. The lack of Mac-1 antigen expression may either be a consequence of the viral transformation or indicate that the AF-1 virus target cell is among the subpopulation of mononuclear phagocytes that does not express this antigen, for example, the histiocytes of the spleen[12]. HA15/A and HA15/S cells expressed Fc receptors, whereas only HA15/A cells could phagocytose immunoglobulin-coated polystyrene particles[13]. HA15 cells released virus that transformed fibroblasts and caused spleen focus formation and splenomegaly. The pathogenic property of this virus was not different from the AF-1 virus rescued from the non-producer cells.

Attempts to establish permanent cell lines from spleen cell cultures or CFU-C of uninfected or Ha-MSV-infected mice have failed; the cell lines ceased to proliferate after 2–3 weeks of culture. As both Ha-MSV and the AF-1 virus contain the *ras* oncogene (Fig. 1), it will be of interest to determine whether the immortalization of a subpopulation of mononuclear phagocytes is a property of either the *ras* oncogene or the viral long terminal repeat of AF-1 virus in combination with the *ras* oncogene. So far, restriction mapping of the genomes of Ha-MSV and AF-1 virus has shown subtle differences between the two in the long terminal repeat region of the genome but not in the *ras* oncogene. Recently, AF-1 virus has been molecularly cloned to pinpoint the genetic elements that make its leukaemogenic properties so unique.

In summary, AF-1 virus is a new murine spleen focus-forming virus carrying a *ras*-related oncogene that possesses the unique property of transforming cells of the mononuclear phagocyte lineage *in vivo*. The AF-1 virus-infected DDD mouse is uniquely appropriate as a model for studying the pathogenesis of human malignant histiocytosis, for which a viral etiology has been proposed[14].

Human T-cell lymphotropic retrovirus type III (HTLV-III), also called lymphadenopathy-associated virus (LAV), has been identified as the aetiological agent of acquired immune deficiency syndrome (AIDS)[1–9]. The sera of most patients with AIDS or AIDS-related complexes, and of asymptomatic individuals infected with HTLV-III, contain antibodies against antigens of HTLV-III[4,10–12]. The characterization of these antibodies and their corresponding viral antigens is important not only for understanding immunity against HTLV-III and the pathology of AIDS, but also for the development of diagnostic methods and preventive vaccine for AIDS. Following the successful establishment of a long-term T-cell line permissive for HTLV-III replication[1], large quantities of virus have been produced, facilitating the purification of viral proteins and the development of mouse monoclonal antibodies

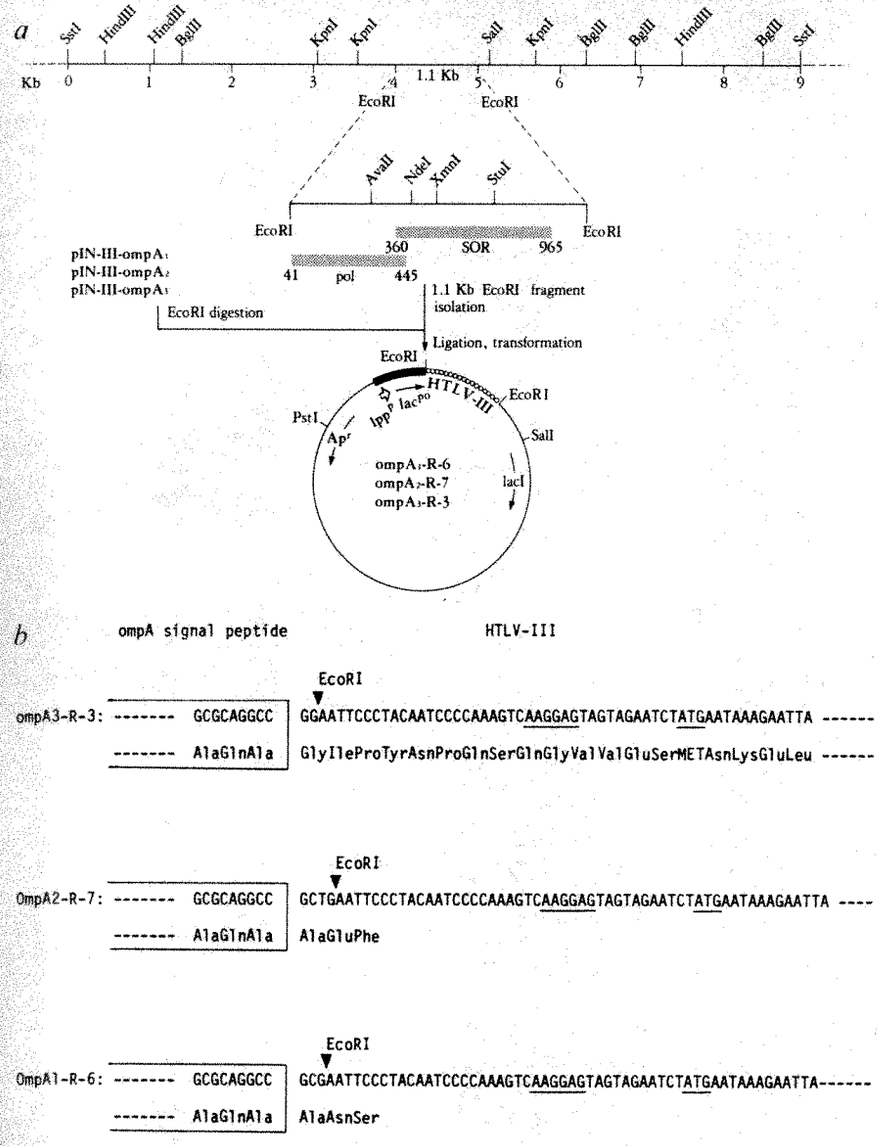

Fig. 1 ***a***, Construction of recombinant plasmids ompA1-R-6 (01R6), ompA2-R-7 (02R7) and ompA3-R-3 (03R3) carrying HTLV-III inserts. The 1.1-kb *Eco*RI fragment was excised from clone λBH10, purified by gel electrophoresis and ligated to plasmid vectors pIN-III-ompA1, -ompA2 and -ompA3 which had been cut previously with *Eco*RI. The ligation mixture was used to transform *E. coli* K-12 strain JA221 (ref. 17) and the resultant ampicillin-resistant colonies were isolated for further characterization. The 15,000-M_r peptide is presumed to start at nucleotide 41 and end at position 445 and the sequence of the short open reading frame extends from nucleotides 360 to 965 (see text). The top line shows the restriction map of HTLV-III insert of clone λBH10 (refs 13, 16). The dotted line indicates the left-hand and right-hand arms of λ vector λgtWESλB. The solid line indicates the HTLV-III DNA. The two shaded regions indicate the two open reading frames included in the 1.1 kb *Eco*RI fragment, the 3′ end of the *pol* gene and the SOR. ***b***, The nucleotide sequence of the ompA signal peptide and the pertinent region of recombinant plasmids 01R6, 02R7 and 03R3. The sequence of the ompA signal peptide is boxed. The postulated Shine–Dalgarno sequence AAGGAG and the initiation codon ATG are underlined. Abbreviations: lpp^p, *lpp* promoter, lac^{po}, *lac* promoter-operator; AP^r, ampicillin-resistance gene.

against several viral antigens[10,24]. More recently, the structure of HTLV-III proviral DNA has been elucidated[13–16]. We now report the production, by genetic engineering methods, of a peptide encoded by a gene segment of HTLV-III. A 1.1-kilobase (kb) *Eco*RI DNA segment from an isolate of HTLV-III was inserted into a *lpp* and *lac* promoter-coupled expression vector, pIN-III-ompA. *Escherichia coli* transformants of this plasmid produced a peptide of relative molecular mass (M_r) 15,000 (15K) which was strongly immunoreactive with anti-HTLV-III antibodies present in sera from AIDS patients. Lysates of the clones expressing this 15K peptide inhibited the reactivity of the p31 virion protein with AIDS sera, suggesting that it is a fragment of the viral p31 protein. The peptide reacted with sera from all 20 AIDS patients but none of the 8 normal controls tested. These results suggest that the peptide may be useful for detecting anti-HTLV-III antibodies in blood samples.

The expression vector used, pIN-III-ompA (ompA), contains the lipoprotein (the most abundant protein in *E. coli*) gene promoter (*lpp*) and the *lacUV5* promoter-operator (Fig. 1*a*)[17]. The ompA vectors also contain the DNA segment encoding the lac repressor, which allows the expression of the inserted DNA to be regulated by *lac* operon inducers such as isopropyl-β-D-thiogalactoside (IPTG). The ompA cloning vehicles contain three unique restriction enzyme sites, *Eco*RI, *Hin*dIII and *Bam*HI, in all three reading frames, so that DNA can be inserted into any of these restriction sites.

Various restriction fragments were excised from the recombinant clone λBH10, which contains a 9-kb HTLV-III DNA insert in the *Sst*I site of the vector λgtWES.λB (ref. 13). These restriction fragments were then inserted into the ompA vectors in all three reading frames and used to transform *E. coli* JA221 cells[17]. Transformants were first screened for HTLV-III DNA by *in situ* colony hybridization using HTLV-III DNA probes[18], and the positive clones then screened for expression of HTLV-III antigenic peptides using HTLV-III-specific antibodies.

This approach identified several gene segments that encode peptides showing immunoreactivity with anti-HTLV-III antibodies, among these a 1.1-kb *Eco*RI restriction fragment. When this fragment was inserted into the ompA vectors in the three reading frames (Fig. 1*a*), IPTG induction of transformants of all three plasmid constructs, designated ompA1-R-6 (01R6), ompA2-R-7 (02R7) and ompA3-R-3 (03R3), produced a 15K peptide that was strongly reactive with anti-HTLV-III antibodies in sera from AIDS patients (Fig. 2). This reactivity was not detected with sera from normal individuals (data not shown).

DNA sequence analysis of the three recombinant constructs confirmed that, as planned, each recombinant had a different reading frame of the HTLV-III (+)-strand coupled to the coding sequence of each vector. Only in 03R3 was the reading frame of the inserted DNA in phase with that set by the signal peptide in the ompA vector; in 01R6 and 02R7 the *pol* gene segment DNA was out of phase (Fig. 1*b*). Examining the DNA sequence closely, we found that there was a 6-base pair (bp) ribosome binding site, AAGGAG (Shine–Dalgarno sequence), located at nucleotide position 24–29 and an initiation codon, ATG, located 11 bp downstream (position 41–43). We believe that the 15K

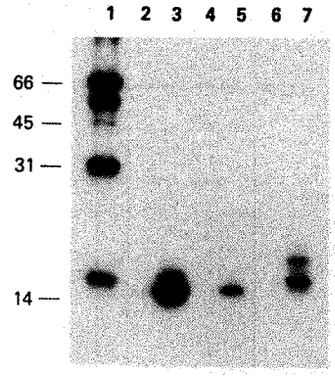

Fig. 2 Immunoreactivity with AIDS sera of HTLV-III antigens produced in bacterial cells containing plasmids 01R6, 02R7 or 03R3. Lane 1, purified HTLV-III virions; lanes 2, 3, 01R6 uninduced and induced with IPTG; lanes 4, 5, 02R7 uninduced and induced; lanes 6, 7, 03R3 uninduced and induced. Numbers on the right represent M_r standards ($\times 10^{-3}$).

Methods. Cells were grown at 37 °C in L-broth containing 100 μg ml^{-1} ampicillin to an A_{600} of 0.2. The cell cultures were then divided into two aliquots; IPTG was added to one aliquot to a final concentration of 2 mM (induced) and the other aliquot received no IPTG (uninduced). After 2 h incubation at 37 °C, the cells were collected and lysed in gel loading buffer[22]. Total cell lysates from the equivalent of 0.2 ml cell culture or purified NP40-disrupted HTLV-III virions were electrophoresed on 12.5% SDS-polyacrylamide gels by the method of Laemmli[22]. The proteins on the gels were then electrophoretically blotted onto a 0.45-μm nitrocellulose filter[23]. The blots were first incubated with a blocking buffer (5% non-fat dry milk, 0.1% Antifoam A, 0.1% Na-azide in phosphate-buffered saline) for 2 h at 37 °C and then with fresh blocking buffer containing 5% goat serum for 2 h at room temperature. AIDS patients' or normal donor sera were then added to a final dilution of 1:100 and the blots were incubated at 4 °C overnight. After incubation the filters were washed three times with washing buffer (0.5% deoxycholic acid, 0.1 M NaCl, 0.5% Triton X-100, 10 mM phosphate *p*H 7.5, 0.1 mM phenylmethylsulphonyl fluoride) for 30 min each and then incubated with fresh blocking buffer containing 5% normal goat serum for 1 h before adding ^{125}I-labelled goat anti-human IgG (10 μCi μg^{-1}) to a final dilution of 1×10^6 c.p.m. ml^{-1}. After 30 min, the iodinated probe was removed and the nitrocellulose blots were washed with washing buffer three times for 20 min each, dried and exposed to Kodak XAR-5 X-ray film.

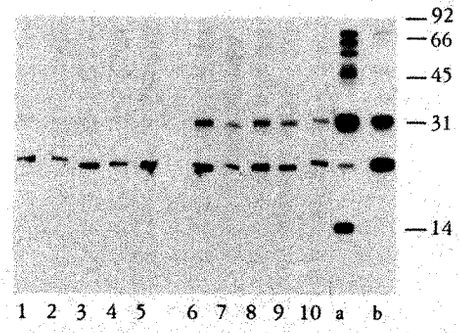

Fig. 3 Inhibition of reaction between HTLV-III antigens and an AIDS serum by 01R6 lysate. Lanes 1–5, 01R6 cell lysate of 50, 75, 100, 200 and 400 μl, respectively; lanes 6–10, control cell lysate of 50, 75, 100, 200 and 400 μl, respectively; lane *a*, no cell lysate (with serum from AIDS patient A60); lane *b*, no cell lysate (with serum from AIDS patient E.Y.).

Methods. Clone 01R6 or control cells in 10-ml cultures were induced with IPTG at an A_{600} of 0.2 and the cells were collected after 2 h, resuspended in 1 ml 10 mM Tris-HCl *p*H 8.0, and sonicated. NP40-treated HTLV-III was fractionated on a 12.5% SDS-polyacrylamide gel and electro-transblotted onto a nitrocellulose filter paper. The paper was cut into ~30 strips which were then incubated with a well-characterized AIDS serum (from patient E.Y., which had elevated anti-p31 antibodies) in the presence of increasing amounts of lysate of clone 01R6 (lanes 1–5) or a negative control (lanes 6–10). The lysates were then used in the competition inhibition immunoassay. The further immunoblotting procedure was performed as described for Fig. 2.

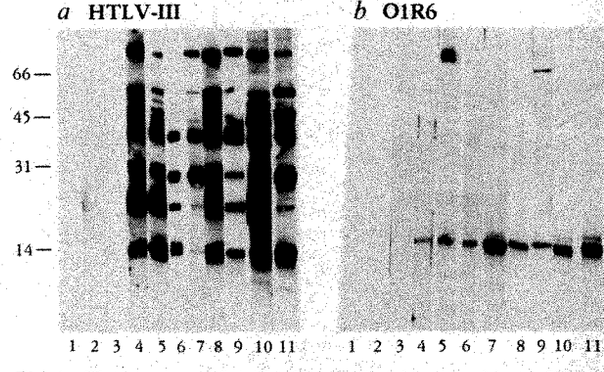

Fig. 4 The presence of antibodies against the recombinant HTLV-III-encoded 15K peptide in sera from AIDS patients and healthy individuals. Purified HTLV-III virus (*a*) or total cell lysate of bacterial clone 01R6 (*b*) were electrophoresed and electroblotted onto nitrocellulose filters, and protein strips were reacted with serum samples as described for Fig. 3. Lanes 1–3, healthy donors; lanes 4–11, AIDS patients.

peptide synthesized by all three recombinants is translated from the transcripts using this internal initiation codon. If this is true, the peptide would start from the ATG located at position 41–43 and end at the stop codon at position 446–448, producing a peptide of 135 amino-acid residues encoded by the 3'-end segment of the *pol* gene of HTLV-III. As further evidence that the 15K peptide is indeed derived from the *pol* gene, clones containing only the 5'-end *Eco*RI/*Nde*I fragment (Fig. 1*a*) still produced the same 15K peptide (data not shown).

In addition to the 15K peptide, the 03R3 construct, in which the reading frame of the HTLV-III DNA *pol* gene is in phase with that set by the vector, produced another two peptides ~19K and 16.5K in size (Fig. 2). It is possible that the 19K peptide contains an additional 35 amino-acid residues, 21 of which are from the signal peptide encoded by the ompA3 vector, with 14 encoded by the inserted HTLV-III DNA itself. The 16.5K peptide may be the processed 19K peptide in which the signal peptide is cleaved.

The 01R6 and 02R7 constructs also produced another peptide of ~17.5 K (Fig. 2) which was weakly reactive with sera from AIDS patients, but whose origin is unclear. Note that the 1.1-kb *Eco*RI fragment contains a second potential coding region, designated as the short open reading frame (SOR), extending from nucleotides 360 to 965 (Fig. 1*a*)[16]. Four of the five AUG methionine codons in this region are near the 5' end of this open reading frame. However, there is no clearly recognizable ribosome binding site at the 5' end of this open reading frame. Furthermore, several recombinant clones containing DNA fragments of the SOR, when inserted into the open reading frame vector pMR100, produced λCI-HTLV-III-β-galactosidase tripartite fusion proteins which showed little immunoreactivity with anti-HTLV-III antibodies in sera from AIDS patients[19].

Because the RNA-dependent DNA polymerase of retroviruses is a minor component of the virions, we were surprised to detect immunoreactivity against the 15K peptide in sera from AIDS patients. To identify this immunoreactive peptide with respect to the banding pattern of HTLV-III virion antigen in SDS-polyacrylamide gel electrophoresis, we used a competition inhibition immunoassay. Identical filter strips containing electrophoresed disrupted HTLV-III virions were incubated with a well-characterized serum from an AIDS patient in the presence or absence of lysates of 01R6, or control bacterial clones. Lysates of 01R6 blocked the immunoreactivity of the viral p31 protein with the AIDS serum, but lysates of control cells did not (Fig. 3). This result suggests that the recombinant 15K peptide encoded by the 3' end of the viral *pol* gene is also a part of another virion protein, p31, in contrast to a previous proposal

that p31 is a cellular protein which co-purifies with HTLV-III virions[10].

We next evaluated the prevalence in AIDS patient sera of antibodies against the 15K peptide. A panel of sera from AIDS patients and normal healthy individuals was tested in Western blot analyses using 01R6 lysate as the source of antigen. All of 20 AIDS sera and none of the 8 normal controls reacted with the 15K peptide (Fig. 4), indicating that most, if not all, AIDS patients produce antibodies against the viral p31 protein.

Thus, the 15K peptide described here seems to be encoded by the 3′ end of the viral *pol* gene located at the 5′ side of the 1.1-kb *Eco*RI fragment and to be related to the HTLV-III virion protein p31. The precise nature of the viral p31 protein remains unclear. However, in other retroviruses, such as avian myoblastosis virus and murine leukaemia virus, the 3′ end of the *pol* gene has been shown to encode, in addition to the reverse transcriptase, an endonuclease, RNase H, which seems to be essential for virus replication[20,21]. The p31 peptide encoded by the 3′ end of the HTLV-III *pol* gene may represent the corresponding RNase H of this virus. Work is in progress to purify and sequence the 15K peptide from bacterial clones expressing it. The peptide is also being evaluated for use as the solid-phase immunoadsorbent in immunoassays screening for anti-HTLV-III antibodies in serum samples.

We thank Dr M. Inouye for providing the ompA vectors, Dr R. Ting (Biotech) for the purified HTLV-III, Dr V. R. Zurawski Jr for helpful discussions, Dr H. Schoemaker and Mr M. Wall for supporting the work, and S. O'Haire and D. Scollon for typing the manuscript.

Hepatitis B virus contains pre-S gene-encoded domains

A. Robert Neurath*, Stephen B. H. Kent†, Nathan Strick*, Patricia Taylor* & Cladd E. Stevens*

One of the open reading frames on hepatitis B virus (HBV) DNA comprises the coding region (designated the *env* gene) for the virus envelope proteins. Studies on messenger RNA transcription suggest that this gene has the potential to code for three related proteins[1]: (1) a protein of 226 amino acids identified as a major protein constituent of the HBV envelope, termed S-protein; (2) a protein with 55 additional amino acids at the N-terminal coded for by a portion of the *env* gene upstream of the S-gene (pre-S); (3) a protein corresponding to the entire *env* gene (pre-S + S). Synthetic peptides from the N-terminals of proteins (2) and (3), and antisera to them have been used to study the occurrence and properties of pre-S sequences. The results presented here provide unambiguous evidence that all three *env* encoded proteins are present in HBV particles; synthetic peptides corresponding to the gene encoding pre-S are highly immunogenic and can be used in diagnostic tests for detection in human sera of antibodies preferentially recognizing HBV; such antibodies, specific for pre-S determinants, are elicited during hepatitis B infection and by immunization with HBV proteins (2) and (3); the hepatitis B vaccine licensed in the United States does not contain pre-S proteins; and the pre-S proteins of the HBV envelope contain domains specifically recognized by liver cells. These findings suggest that pre-S determinants are important in virus-neutralizing responses and should be present in HBV vaccines.

Table 1 Interaction of HBV (HBsAg) with human hepatoma cells

Cells used	Antibodies added	Percentage of cells attached to HBsAg-cellulose
HepG2 (human hepatoma)	—	80–95 (14 experiments)
HeLa	—	10–20
Rat hepatocytes	—	10–20
HepG2	Anti-pre-S(120–145) (15 mg IgG ml^{-1})	60
HepG2	Anti-pre-S(12–32) (15 mg IgG ml^{-1})	30
HepG2	Anti-pre-S(120–145) + anti-pre-S(12–32) (7.5 mg IgG ml^{-1} each)	20
HepG2	Anti-HBV serum devoid of anti-S-protein[5]	8
HepG2	—	0 (BSA-cellulose)

HBV (HBsAg) was attached to *N-N′-p*-phenylenedimaleimide-derivatized sulphydryl cellulose under conditions described for linking of pre-S(120–145)[2]. About 4 mg of HBV (HBsAg) was linked to 1 g of the cellulose derivative. A control cellulose derivative was prepared by linking bovine serum albumin (BSA) to the activated matrix. The cellulose derivative (40 mg) suspended in TS (0.14 M NaCl, 0.01 Tris-HCl, 0.02% NaN_3 *p*H 7.2) containing 10 mg ml^{-1} BSA (TS–BSA) was mixed with $\sim 2 \times 10^6$ washed HepG2 human hepatoma cells[15], suspended in TS–BSA and incubated for 30 min at 37 °C, followed by 1 h at 4 °C. HeLa cells and clone 9 normal rat liver cells (American Type Culture Collection) were used as controls. The cell/cellulose mixtures were layered on top of 1 ml of 33% (w/w) Hypaque and centrifuged at 3,000 r.p.m. for 2 min. The cellulose derivative with attached cells pelleted in these conditions; unattached cells recovered from the Hypaque/TS–BSA interphase were diluted five-fold in TS–BSA and pelleted by centrifugation. The relative proportion of adsorbed and unadsorbed cells was determined by measurement of lactate dehydrogenase (LDH) activity in appropriate aliquots of cell lysates obtained after exposure to the detergent Triton X-100 (5 mg ml^{-1} in H_2O). LDH activity was determined using Sigma diagnostic kit no. 500. In initial experiments, similar results were obtained with HBV-cellulose and HBsAg-cellulose. Because of the limited quantities of HBV available, HBsAg-cellulose was used in subsequent experiments.

Peptides corresponding to the N-terminals of proteins (2) and (3) were synthesized and used to raise antisera in rabbits. High levels of anti-peptide antibodies were elicited (Fig. 1*A*, *B*).

The use of anti-pre-S (120–145) in Western blots of HBV particles identified components of relative molecular mass (M_r) ~33,000 (~33K), ~36K, ~45K and ~67K (Fig. 1*C*, lane *d*). A similar experiment with anti-pre-S (12–32) identified the ~45K protein alone (data not shown), indicating that this component corresponds to protein (3), the full-length translation product of the *env* gene, while the ~33K and ~36K components correspond to protein (2)[2–4]. The ~45K component was not detectable in Western blots of 22-nm sub-viral particles lacking the nucleocapsid (hepatitis B surface antigen, HBsAg)[2]. This is consistent with previous evidence for antigenic determinants on the HBV envelope which are underrepresented or absent from

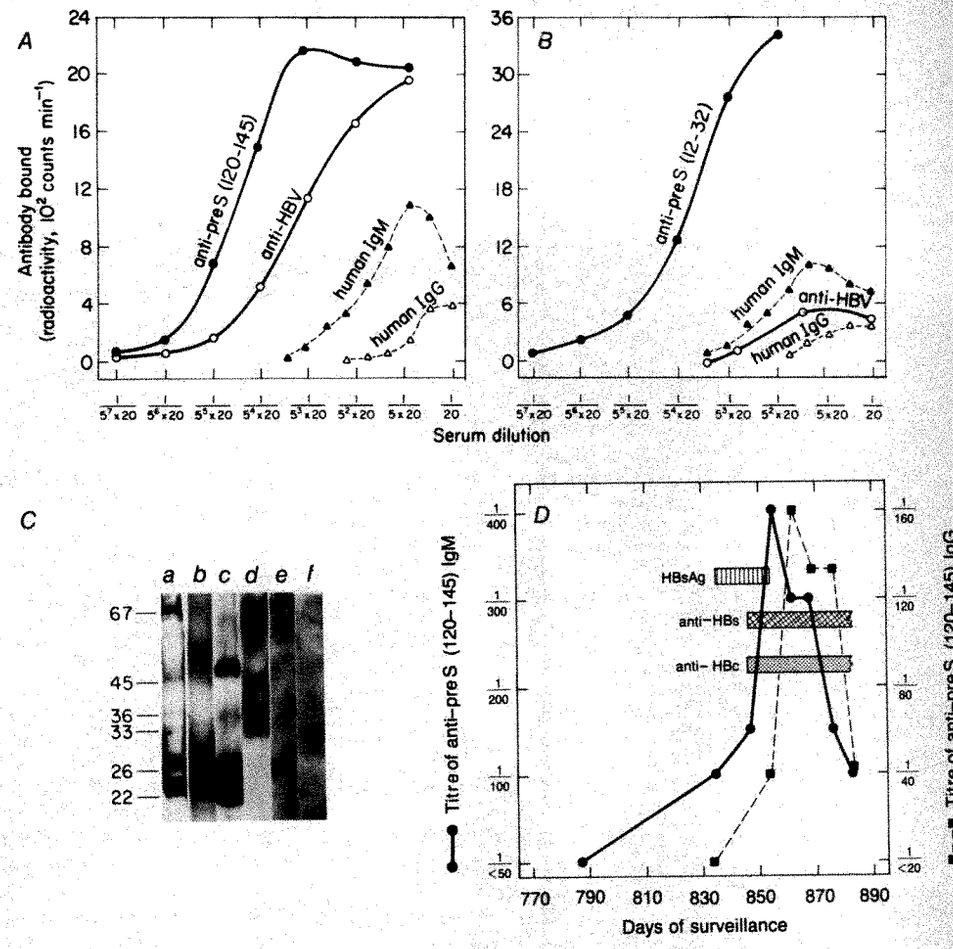

Fig. 1 ***A, B,*** Radioimmunoassays of IgG antibodies in serial dilutions of: rabbit antisera to pre-S (120–145) (*A*) or pre-S(12–32) (*B*) (●), to HBV (○) (devoid of antibodies to S-protein detectable by RIA[5]); IgG (△) and IgM (▲) in serum of a patient who had recovered from hepatitis B. The latter serum was obtained before antibodies to the S-protein were detectable. Immulon 2 Removawell strips (Dynatech Laboratories) were coated with 20 μg ml^{-1} of either free pre-S(120–145) or pre-S(12–32), then coated with gelatine (2.5 mg ml^{-1} in 0.1 M Tris, *p*H 8.8). The conditions for coating and the double-antibody RIA were described elsewhere[2,13]. The peptides corresponding to subtype adw2 (ref. 16) were synthesized as described elsewhere[2]; their sequences are MQWNSTAFHQTLQDPRYRGLYLPAGG [pre-S(120–145)] and MGTNLSVPNPLGFFPDHQLDP (pre-S(12–32)], according to the one-letter amino acid code. ***C,*** Polyacrylamide gel electrophoresis of HBV (*a, d*), serum-derived HBsAg after pepsin treatment (components of the Merck, Sharp & Dohme hepatitis B vaccine)[10] (*b, e*), and HBsAg produced in yeast[11] and lacking sequences corresponding to pre-S protein (*c, f*). Separated polypeptides were either stained with silver (*a–c*) or transferred to nitrocellulose and reacted with anti-pre-S (120–145) followed by ^{125}I-labelled protein A (*d–f*)[2]. ***D,*** Development of antibodies to the pre-S gene-encoded protein of HBV during acute hepatitis B infection. Antibodies to pre-S (120–145) were quantified; HBsAg, anti-HBs and anti-HBc were assayed using commerical test kits (Abbott Laboratories). The broken line at the end of the bars corresponding to the different markers of HBV infection indicates their presence at the end of surveillance. Antibody titres represent the highest dilution of serum at which radioactivity counts corresponding to the specimens, divided by counts corresponding to equally diluted control serum, were ≥2.1.

HBsAg[5–9]. To confirm this, we studied the reaction of an anti-HBV serum with two synthetic peptide analogues of the pre-S protein; the antiserum reacted at high dilutions with both peptides (Fig. 1*A, B*).

The synthetic peptides were also recognized by antibodies in sera of individuals who had just recovered from acute hepatitis B (Fig. 1*A, B*). Figure 1*D* shows the time course of development of antibodies recognizing pre-S (120–145) in a selected patient; similar results were obtained when antibodies recognizing pre-S (12–32) were assayed (data not shown). IgM antibodies recognizing the peptides were detected during HBsAg antigenaemia before antibodies to the S-protein (anti-HBs) or to hepatitis B core antigen (anti-HBc) were detectable. After production of the latter two antibodies, the titre of antibodies with anti-pre-S specificity declined. In some cases, antibodies recognizing the synthetic peptides were present even before HBsAg was detected in plasma, or when HBsAg never appeared in blood and the only marker for hepatitis B was anti-HBc and later anti-HBs.

HBV particles were recognized much more efficiently than HBsAg in radioimmunoassay (RIA) tests with anti-pre-S (120–145) (Fig. 2) or with antibodies to HBV particles (data not shown); this result implies that determinants specific for the preS region of protein (2) are more abundant in HBV than in HBsAg. Treatment of HBsAg with pepsin, a step used in the preparation of hepatitis B vaccine[10], resulted in a ~10^3-fold decrease in reactivity to anti-pre-S (120–145) (Fig. 2). HBsAg from vaccines derived either from infected plasma or produced in yeast[11] had ≤1/5,000 of the reactivity of intact HBsAg in these tests (data not shown; see also Fig. 1*C*). Human subjects vaccinated with either of these vaccines did not develop detectable antibodies recognizing either of the two synthetic peptides, whereas 7 out of 12 individuals who received a vaccine consisting of intact HBsAg[12] developed these antibodies.

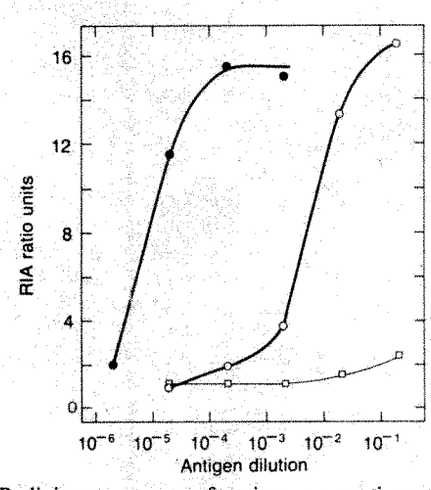

Fig. 2 Radioimmunoassays of various preparations containing HBV-specific proteins on polystyrene beads coated with anti-pre-S(120–145) IgG. The antigens tested were: HBV (●), HBsAg (○) and HBsAg treated with pepsin (1 mg ml^{-1} HBsAg, 50 μg ml^{-1} pepsin in 0.1 M glycine-NCl *p*H 2.2, 2 h at 37 °C) (□). RIA performed as described elsewhere[2]. The concentration of HBsAg S-protein was adjusted to the same level in all preparations based on RIA tests (AUSRIA, Abbott Laboratories).

Quantitative aspects of the immunological cross-reactivity between pre-S gene-encoded sequences exposed on HBV

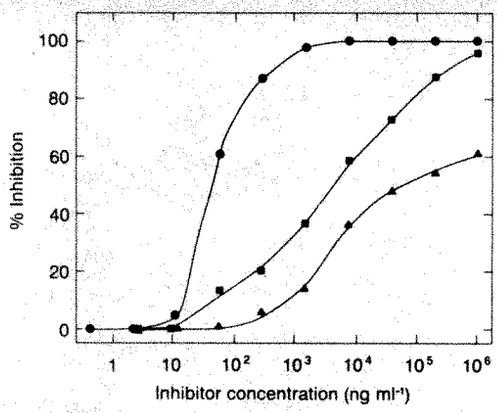

Fig. 3 Inhibition of the reaction of anti-pre-S (120–145) IgG with a pre-S(120–145)-β-galactosidase conjugate. ●, pre-S(120–145). The HBV (■) and HBsAg (▲) preparations contained the same concentration of HBsAg S-protein as determined by RIA (AUSRIA, Abbott Laboratories). The inhibition tests and the preparation of peptide-β-galactosidase conjugates were as described elsewhere[13,17]. Anti-pre-S(120–145) did not react with unconjugated β-galactosidase. The concentration of free peptide sufficient for ~50% inhibition of the reaction of pre-S(120–145)-β-galactosidase with anti-pre-S(120–145) is ~1/100 (w/w) of that for HBV. However, as the M_r of pre-S(120–145) is ~3K and that of HBV protein components reacting with anti-pre-S(120–145) (representing a minor (<20%) portion of the total HBV mass) is between ~33K and ~67K, the calculated molar concentration of the HBV pre-S protein required for 50% inhibition is approximately the same as that of the peptide analogue.

particles (or on HBsAg) and the synthetic peptide analogues were studied in more detail. The results (Fig. 3) indicate that HBV inhibited completely the reaction between anti-pre-S (120–145) and pre-S (120–145)-β-galactosidase. There is no significant population of anti-peptide antibodies which recognizes the synthetic peptide but not the native protein. Such antibody subpopulations are frequently observed in other antisera raised against synthetic peptide analogues of viral proteins[13,14]. The molar concentrations of HBV and pre-S (120–145) required for 50% inhibition were approximately the same, indicating that the antigenic determinants on the peptide analogue and on the corresponding segment of the HBV envelope protein(s) are identical or closely related. HBsAg has about one-fifth of the inhibitory activity of HBV. The inhibitory activity of pepsin-treated HBsAg was ≤1/1,000 of the activity corresponding to intact HBsAg.

To explore the involvement of pre-S gene-encoded HBV domains in attachment to cell receptors, we studied the reaction of HBsAg and HBV with liver cells. The results (summarized in Table 1) show that HBsAg (HBV) reacts with human hepatoma cells and that this reaction is inhibited by antibodies to synthetic peptides corresponding to the pre-S gene. Normal rabbit IgG, as well as antibodies to the S-protein (elicited by immunization with pepsin-treated HBsAg), had no inhibitory effects.

In conclusion, pre-S determinants clearly play an important role in hepatitis B virus infection and in the human immune response to HBV, and therefore should be included in hepatitis B vaccines.

We thank T. Huima, P. Sproul and E. Seda for technical assistance; Dr D. G. George for computer searches; Drs E. Emini, W. J. McAleer, F. B. Hollinger and J. L. Dienstag for hepatitis B vaccines and human sera; and Dr W. J. Rutter for providing us with unpublished data.

Intragenic recombination leads to pilus antigenic variation in *Neisseria gonorrhoeae*

Per Hagblom*†, Ellyn Segal†, Elizabeth Billyard† & Magdalene So†

* Department of Microbiology, University of Umeå, S-901 87 Umeå, Sweden
† Department of Molecular Biology, Scripps Clinic and Research Foundation, 10666 N. Torrey Pines Rd, La Jolla, California 92037, USA

The pilus of the bacterium *Neisseria gonorrhoeae* is a fimbriate surface structure which promotes attachment of the bacterium to host epithelial cells[1–4]. Gonococcal pilus phase variation is characterized by a rapid on/off switch in which piliated (P^+) cells throw off non-piliated (P^-) variants and vice versa. Two regions of the gonococcal chromosome (*pil*E1 and *pil*E2) act as pilin expression loci[5], reminiscent of the *MAT* locus in the yeast *Saccharomyces cerevisiae*[6], while several other chromosomal regions contain silent (non-expressing) pilin sequences[5]. Biochemical and antigenic diversity is seen in pili from a wide variety of clinical isolates[7–11]. Pilins (pilus subunits) are composed of conserved N-terminal and variable C-terminal regions[12]; the conserved region of gonococcal pilin is also found in pilins produced by widely disparate bacteria[13–15]. We show here that the gonococcal pilin undergoes antigenic variation *in vitro* and *in vivo*. The protein consists of constant, semi-variable and hypervariable regions. This antigenic variation probably involves gene conversion of mini-cassettes of pilin information.

To study pilus antigenic variation in *N. gonorrhoeae*, lines of phase variants of strain MS11 were established whose members differ from each other in their piliation state (Fig. 2). Pilin transcripts from these derivatives were sequenced by the primer extension method[16]. MS11 can express at least seven different pilin genes (Figs 1*a*, 2). Within one line of derivatives, the P^- to P^+ switch resulted in the expression of a new variant (for example, 2C, E, G) or the re-expression of a former variant (for example, 3G, 10E). Thus, pilin information is not lost during phase or antigenic switching. Those derivatives which express variant genes produce pili that are antigenically different from those of the MS11 progenitor (Fig. 2).

Attempts to obtain sequences of the 3′-untranslated region of the pilin messenger RNA of variants 2C and 3I were unsuccessful (Fig. 1). These alternative sequences are probably the result of aberrant recombination events occurring between a silent locus and the expression site. Our sequence data on several expression loci in the P^- state indicate that this region is often affected by the events regulating the P^+ to P^- switch[17].

The pilin protein can be divided into three regions (Fig. 1). The first 53 amino acids are always conserved. A silent change has occurred at position 47 in variants 2C, ML3 and WG3 (data not shown), suggesting that the constant (C) region may be shorter than 53 residues. Many amino-acid substitutions are found within the semi-variable (SV) region (residues 54–114). Most changes here involve charged amino acids, but the introduction of a positive charge is often balanced by a second

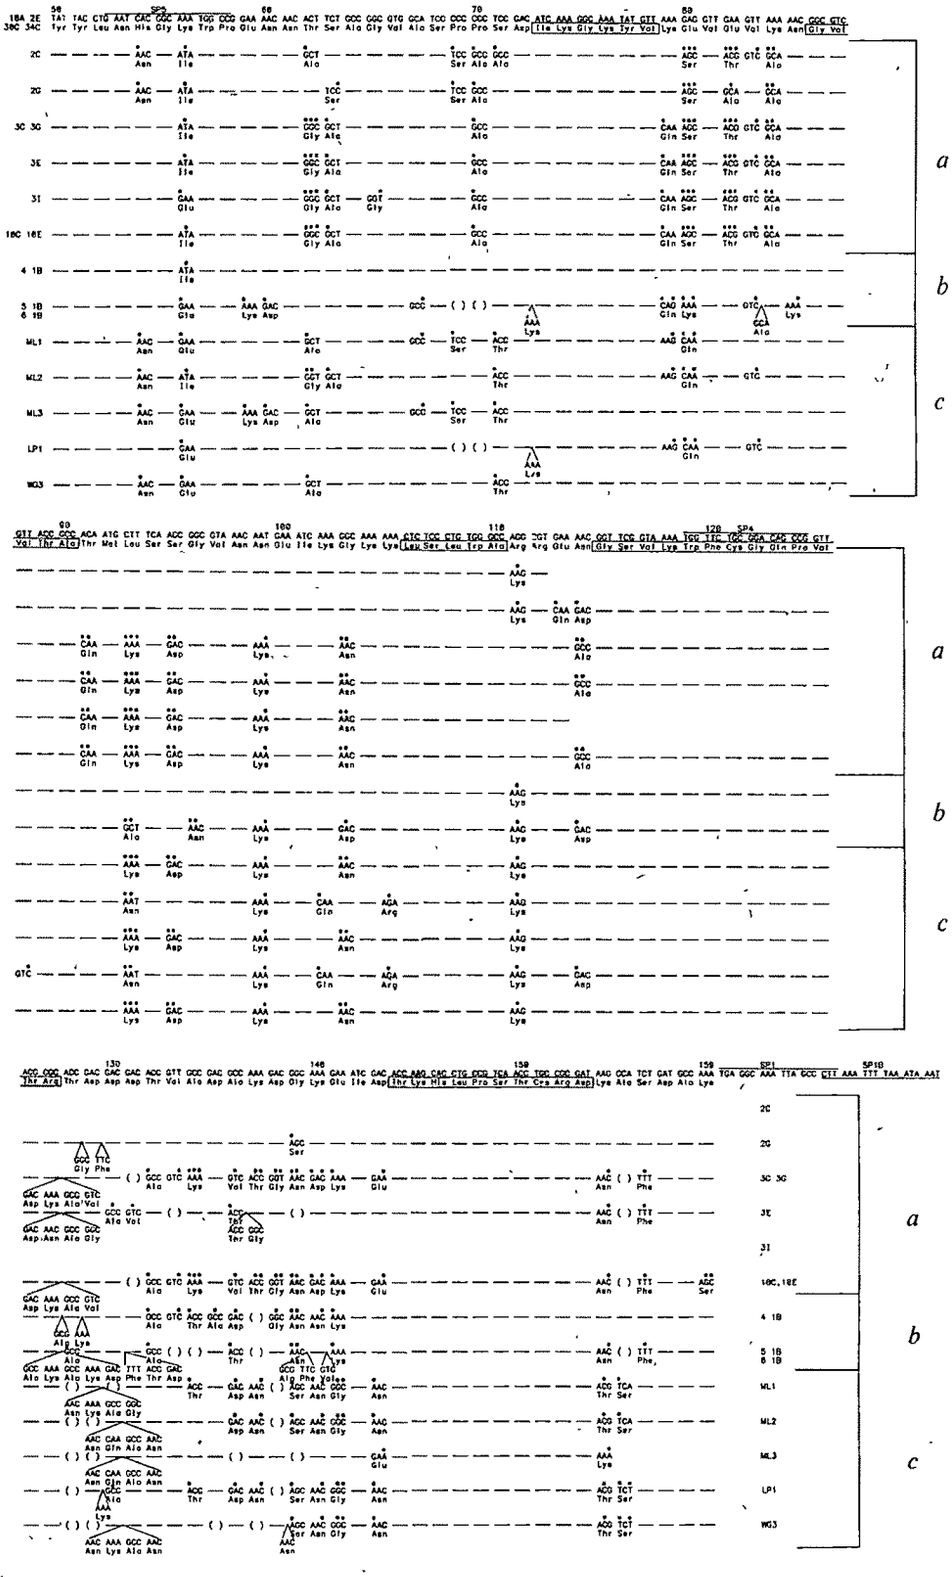

Fig. 1 Pilin gene sequences including deduced amino-acid sequences from residue 50 to the C-terminus. The MS11 pilin DNA and amino-acid sequences[5] are shown at the top. This sequence is also found in variants 2E, 10A, 30C and 34C. *a*, Sequences from the MS11-derived P^+ strains; *b*, pilin gene sequences in the expression loci of the MS11-derived P^- variants; *c*, sequences of the pilins from the clinical isolates. Strains ML1, 2 and 3 were obtained from the same individual at different times; LP1 and WG3 were isolated from two other individuals (P. F. Sparling, manuscript in preparation). Dashes indicate no sequence differences observed in these positions. Parentheses indicate codon deletions. Codon and amino-acid changes are indicated where found. If the sequence change does not alter the amino acid at that position, only the codon change is shown Dots above the bases indicate those positions within the codon which have changed. Insertions are presented below the variant sequences. Boxed amino acids in the top line represent the regions found to be conserved by comparison of all variant sequences. Primers were made by an Applied Biosystems 380A oligonucleotide synthesizer to regions which, by comparison of the different sequences, were observed to be invariant. Primer extension sequencing was done essentially as described previously[16], except that kinase-treated primers were used. The reverse complement of the sequence of each primer used is indicated by a line above or below the topmost DNA sequence. As a control for the accuracy of the technique, we have sequenced the 10A derivative and found it to be identical to that of the pilin gene from the progenitor previously determined by the Maxam-Gilbert technique[5]. A synthetic oligonucleotide complementary to a variant sequence was protected by mRNA from mung bean nuuclease digestion to the same extent as a synthetic oligonucleotide complementary to the pilin signal sequence. Thus, the pilin mRNA which was extended was also the major species expressed by the variants. Furthermore, the synthetic DNA did not prime the synthesis of any complementary DNA in RNA preparations from P^- B-series variants.

compensating substitution nearby, and vice versa. For example, a comparison of variants 10A and 10C shows that 10C has lost all charged amino acids at positions 79–84, but compensating charges in 10C can be found approximately 10 residues downstream. At the nucleotide level, these substitutions frequently involve two or three changes, both transitions and transversion, in a codon. The carboxy-terminal portion of the protein is highly variable; in addition to amino-acid substitutions, in-frame insertions and deletions of one to four codons occur. The amount of variability here would explain the low immunological cross-reactivity of pili from different strains, as this part is immunodominant over the conserved portion of the protein[11,18]. Two regions which bracket this hypervariable (HV) segment are always conserved; these centre around the cysteines at positions 121 and 151, are 13 and 10 amino acids long, respectively, and may represent epitopes common to all gonococcal pili.

In most variant genes, both the *SV* and *HV* sequences are entirely different from those of the progenitor. However, pilin variants of line 3 share the same *SV* gene segment but different *HV* ones. Thus it is possible to assemble complete genes by mixing *SV* and *HV* gene segments, a mechanism which would considerably increase the antigenic repertoire.

The absence of a good animal model for gonococcal infections has hampered the study of *in vivo* pilin antigenic variation.

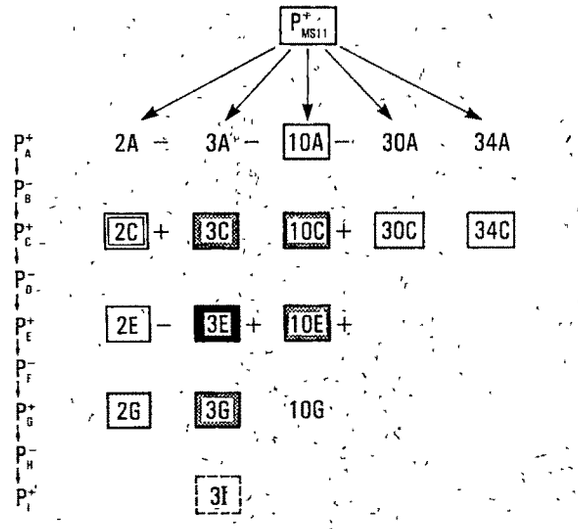

Fig. 2 Left-hand side, a schematic representation of the protocol used for deriving the lines of pilus variants of strain MS11. From the original MS11 strain, which is P^+, several independent P^+ colonies were randomly picked. (Piliation can be scored as differences in colony morphology on a plate.) Each P^+ isolate is the start of a line, each line is given a number and each constitutes the A-series, all of which are identical to the MS11 progenitor. P^- revertants are then randomly picked from each P^+ A-series. These have undergone a P^+ to P^- phase switch once and are now in the B-series. Subsequently, P^+ backswitchers can be isolated from the different lines in the B-series; they now belong to the C-series. This procedure was used to obtain lines of variants which have undergone the phase switch several times. All manipulations were done in a PII^-, or opacity$^-$, background. Piliation phenotype is given as P^+ or P^-, for piliated or non-piliated variants, respectively. The subscripts A–I denote the position within the series to which each variant belongs. The right-hand part of the figure is a schematic representation of the pilus sequence information obtained from the P^+ variants from lines 2, 3, 10, 30 and 34. Each variant sequence is denoted by the style of the box surrounding the strain number. For example, the progenitor P^+_{MS11} (at the top of the figure), 10A, 30C, 34C and 2E all express the same pilin gene variant. 2C, 3E, 2G and 3I each express a unique gene variant. Those strains which produce pilin antigenically different from that of the progenitor are indicated by +, next to the boxes, while those strains which produce pilin identical to that of the progenitor are marked by −. The absence of + or − indicates that the immunological identity of the pilin from these variants has not been determined. Immunological identity is determined by immunodiffusion[24] using crude pili preparations and antiserum directed against pili from the MS11 progenitor.

Recently, an epidemic of gonorrhoea occurred[19] whose origin could be traced to a single source and whose isolates were shown to be members of the same strain (P. F. Sparling, manuscript in preparation). We have chosen isolates from three patients for our sequence studies. One series (ML1, 2, 3) was obtained from a patient who was repeatedly infected between successful courses of antibiotic therapy. Two other isolates, LP1 and WG3, were from different patients. Our data (Fig. 1*c*) show that pilin antigenic variation did occur *in vivo* during the epidemic. It also occurred in the ML isolates obtained from a single individual at various times. However, because antibiotic therapy was instigated between each bout of infection and no sera were available from this patient, we cannot determine whether pilus antigenic variation in these cases was caused by the selective pressure exerted by the host immune response or whether these individuals were infected by partners carrying an already variant strain. However, it is clear that a single gonococcal source expressing one pilus type can, during the course of the epidemic, give rise to isolates which now produce variant pili. The C, SV and HV regions defined by the MS11 sequences are also observed in these variants. Thus, the events contributing to the antigenic variation seen *in vitro* accurately represent those which control variation *in vivo*.

The P^+ to P^- phase switch involves deletion of pilin sequences from one of the two expression loci[5]. In P^- variants 4.1B, 5.1B and 6.1B, we have observed a deletion from only one locus[5]. These variants are non-piliated, and their remaining intact expression site is not transcribed (data not shown). However, *Escherichia coli* harbouring clones of these intact expression sites make pilin transcripts, suggesting that phase variation also involves a switch-induced regulator. Examination of the pilin transcripts derived from *E. coli* shows that sequence variation in 4.1B, 5.1B and 6.1B has occurred during the P^+ to P^- switch (Fig. 1*b*). The new gene variants have all the characteristics observed for the other P^+ backswitchers and, therefore, probably encode functional pilins. These observations suggest that pilus phase and antigenic variation are closely, if not obligately, linked.

Our data strongly suggest that the pilus of *N. gonorrhoeae* can undergo extensive antigenic variation. The mixing of *SV* with *HV* gene segments predicts that the silent loci will contain truncated pilin sequences. Thus, antigenic variation would involve a multiple-step recombination event in which sections of the pilin gene are joined successfully. The generation of new pilin variants may involve those mechanisms postulated for the generation of immunoglobulin diversity (see refs 20, 21), that is, somatic mutations in the silent copies, unequal crossing-over and/or imprecise joining of *SV* and *HV* gene segments (see Fig. 1*a*, line 3). Also, the tendency of MS11 derivatives to express certain variant sequences could be explained by a mechanism similar to that governing the preferential use of certain joining sequences in pre-B-cell immunoglobulin heavy-chain switching[22]. Pilin sequences close to those involved in the initial pairing event between the silent and experession loci would be expressed preferentially.

Whether other bacterial pili undergo extensive antigenic variation is unknown. The *Moraxella bovis* chromosome contains multiple pilin gene sequences (C. Marrs, personal communication). *E. coli* K-88 pilus[23] and P-specific pilus (S. Normark, personal communication) variation involves in-frame insertions and deletions as well as single-base changes in specific regions of the structural gene. Thus, the mechanisms used by bacteria to generate immunologically variant surface proteins may be very similar, if not identical.

The nonlinear Poisson–Boltzmann equation

SPITZER[1] has reminded us that the nonlinear Poisson-Boltzmann equation (NPBE) contains a logical inconsistency. An early incisive analysis of this inconsistency was given by Onsager[2] 50 years ago. Unhappily, more recently, a considerable confusion[1,3] has accrued concerning the nature and consequences of the inconsistency. Spitzer's[1] statement that "the NPBE violates the important electrostatic theorem of additivity of electrostatic potentials" is simply incorrect, and his recommendation that "the linearization of the NPBE is desirable, in principle" is entirely inappropriate.

First we consider the nature of the inconsistency. Onsager[2] was concerned with the microscopic NPBE as it is used to describe the potential generated by a single ion in solution that is screened by the response to it of all the other ions in the electrolyte. As Onsager makes clear, the inconsistency derives from the replacement of the potential of mean force, $w_j(r)$, in the correct Boltzmann relation (his equation (21); ref. 2), by the simpler electrostatic potential energy $e_i\psi_j(r)$ to obtain what is finally an inconsistent Boltzmann relation (his equation (13); ref. 2). The replacement is made in order to write a one-particle NPBE. Note that neither the Poisson equation nor the superposition theorem of electrostatics as such is germane to the inconsistency studied by Onsager. The confusion is compounded by a supposed connection of the linear superposition of electrostatic potentials to a linear dependence of space charge ρ on potential ψ (refs 1,3). In actuality, the linear superposition theorem of electrostatics[4] holds for an arbitrary distribution of space charge $\rho(r)$. Thus, in the analogue to the NPBE appropriate to Fermi–Dirac statistics, namely, the Thomas–Fermi equation[5], $\rho \propto \psi^{3/2}$. For space-charge-limited currents in a planar vacuum diode[6], $\rho \propto \psi^{-1/2}$; in the analogous solid-state diode[7], $\rho \propto \psi^{-1/3}$, and so on.

We next take up the consequences of the inconsistency. As noted above, the inconsistency refers directly to the microscopic NPBE. However, it is important to note that most of the literature on the NPBE since World War II, including the Spitzer letter[1], is not concerned with this equation but rather with the macroscopic NPBE. This latter equation describes the spatial dependence of the average potential generated by relatively large, charged surface(s) in contact with the electrolyte. This local average potential is what remains after all microscopic fluctuations have been averaged out. For the macroscopic NPBE a new phenomenon comes into play when linearization finally fails (that is, at high surface-charge concentrations), which is the formation of a counter-ion condensate close to the surface[8]. Fixman[9], in a theoretical study of the problem within the framework of statistical mechanics, pointed out that substantial errors deep in the condensate lead to far smaller errors outside the condensate. He aptly described this phenomenon as "the buffering action of 'the condensed phase'" (ref. 9). This very pronounced decoupling of a large surface charge from the 'distant' bulk electrolyte is also a direct mathematical consequence of the NPBE, as shown for planar geometry by Verwey and Overbeek[10]. The buffering action of the condensate, as predicted by the NPBE, is even more striking for cylindrical and spherical geometries, as shown by numerical studies of this equation by Lampert and Martinelli (to be published elsewhere). Fixman's numerical calculations led him to conclude that the NPBE is acceptable[9] up to local, condensate concentrations as high as 2–3 M, provided that the bulk salt concentration does not exceed ~0.1 M, which happens to be, approximately, that for physiological saline. It is also relevant here and perhaps not widely known that some 15 yr after his incisive criticism of the microscopic NPBE, Onsager used the macroscopic NPBE to calculate 'The effects of shape on the interaction of colloidal particles'[11].

Spitzer[1] alludes to the difficulty of testing experimentally the Gouy–Chapman–Stern (GCS) model for incorporating adsorption into double-layer theory, as constructed with the NPBE. If that is the situation in electrochemistry and colloid chemistry, then matters are improved considerably in biophysical studies of charged phospholipid bilayer membranes immersed in an aqueous solution. McLaughlin *et al.*[12] showed, by adding small concentrations of divalent cations to a host solution of monovalent ions, that the observed shift in membrane potential disagreed strongly with predictions of linearized PB theory, but agreed adequately with GCS theory. In a recent critique of the work of several groups using various experimental techniques, McLaughlin concludes[13] "that fortunately, the GCS theory appears to be a good first approximation for describing the adsorption of cations to bilayer membranes".

Homologies in the avian tarsus

MCGOWAN has recently presented evidence from the avian tarsal joint for a wide taxonomic separation between ratite and carinate birds. He implies that the pretibial bone of carinates is formed by ossification of a portion of the cartilaginous precursor of the calcaneum (a "calcaneal spur"), while in ratites the comparable structure is an ascending process of the astragalus. However, the youngest specimen he described was a 12-day-old quail embryo. Examination of a large series of cleared and stained chicken embryos shows that the 7-day-old embryos have separate cartilaginous calcania, astragali and tibiae, but no ascending processes or pretibial bones. Eight-day-old chicken embryos show a separate triangular pretibial chondrification above the calcaneum which does not appear to be part of either the astragalus or the calcaneum. On day 9 the pretibial, astragalar and calcaneal cartilages fuse. The pretibial cartilage appears to fuse with both the calcaneal and astragalar cartilages. Only in the fused state could one mistake the pretibial chondrification for an extension of the calcaneum. By day 17 the pretibial bone (calcaneal spur of McGowan[1]) has begun to ossify; at this point it is the only tarsal bone undergoing ossification (Fig. 2*b–d* of ref. 1). Thus, the pretibial bone is the last carinate tarsal element to chondrify and the first to ossify.

McGowan[1] shows that the first bone to ossify in the tarsal complex of ratites is the "ascending process". We believe that this concordance between the ossification of the ascending process of ratites and the pretibial bone of carinates would be hard to explain if they are not the same bone. This is especially true when we consider that the calcaneum is the last bone to ossify in McGowan's preparations.

McGowan[1] describes the "ascending process" of ratites as an ossification with a disk-like base and separate from the astragalus. He describes an early stage in the development of the distal end of the tibiotarsus as comprising a medial ossification and a lateral cartilaginous area. The lateral cartilaginous area has a dorsal spur which he considers to be "homologous with the precursor of the carinate pretibial bone". The enlargement of the astragalus found in some ratites might be a derived character state related to neoteny. The earlier ossification of the astragular portion of the joint may increase the relative

importance of the astragalus in highly neotenic birds. Despite McGowan's statements, the pretibial bone seems to represent both a separate chondrification and ossification in carinates; we believe that this is also the case in ratites and that the difference (if it exists) between ratites and carinates is the result of varying amounts of overlap with the calcaneum and the astragalus. Because of the extreme lateral placement of the pretibial bone in some carinates, it may be confined to the region above the calcaneum (see Fig. 11 of Martin *et al.*[2]), and after the chondrification has fused with the calcaneum it may resemble a 'spur' of that bone. On the other hand, falcons have the pretibial bone very centrally situated as in the ostrich, and most, if not all, of the fusion of the distal end of the pretibial bone is with the astragalus (Fig. 179 of ref. 3). A juvenile swan, *Cygnus buccinator* [Kansas University 79260], shows a pretibial bone ossifying separately from the calcaneum and partially overlapping the astragalus; except for its slightly more lateral position, it corresponds to McGowan's description of the "astragalar process of the ostrich" which is a "well-ossified ascending process, expanding distally into a disk of bone".[1] We believe that the present evidence indicates that ratites and carinates have a homologous ossified ascending process (pretibial bone) separate from both calcaneum and astragalus, but that the position of this process may vary. We believe that, as originally suggested, the pretibial bone is a neomorph ossification providing a derived character for birds. The late chondrification of this element supports such an interpretation. The Mesozoic birds (*Archaeopteryx*, *Enaliornis*, *Baptornis* and *Hesperornis*) have the pretibial bone laterally placed and fused to the calcaneum as in carinates, but not as in theropods (Fig. 1*b* of ref. 1), and we would therefore caution against arguing that the pretibial bone of carinates is a derived character state within the Class Aves.

To view these results as in any way confirming the theropod origin of birds would be to beg the question. The only way McGowan could conclude that the ratite tarsal condition is more primitive than that of the carinates is by already assuming that theropod saurischians are the out-group most proximate to birds; this approach does not address the fact that pseudosuchians and crocodilians are also contested nearest out-groups[4-7]. McGowan's own interpretation of his material would indicate that the bulk of the known birds (the carinates) do not have a theropod-like ascending process.

We thank C. Wyttenbach and J. Garrison for the use of cleared and stained chicken embryos. H.-P. Schultze and M. Mengel critically read the manuscript, and R. Hermann typed it. Support for work on bird origins has been funded by NSF DEB 7821432, KU 3251-5038, and National Geographic grant 2228-80.

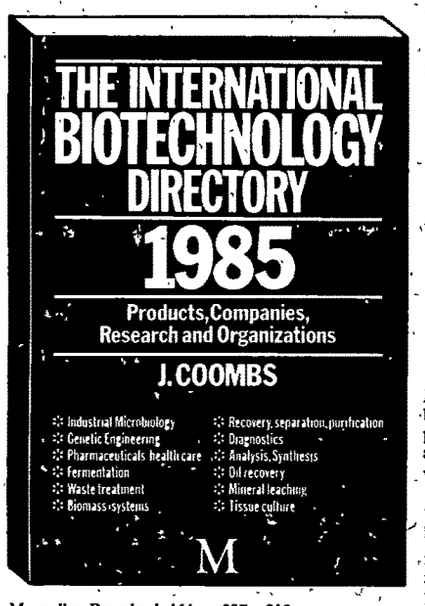
MCGOWAN REPLIES—According to Martin and Stewart, the ascending process of the carinate tarsus commences as a chondrification independent of the cartilaginous astragalus and calcaneum. This subsequently ossifies as a separate element, and a similar ontogeny is believed to occur in ratitites. The pretibial bone thus formed, a new element which is not homologous with the ascending process of theropods, provides a shared derived character for birds.

My X rays of juvenile ostriches (ref. 1, Fig. 3*b*–*c*) confirmed Huxley's[2] belief that ratites, like theropods, have an ascending process that is continuous with the bony astragalus. Whether this process develops in ratites as an integral part of the astragalus, or, as Martin and Stewart contend, as an independent chondrification, and ossification, can only be determined embryonically. The earliest ratite embryos available to me were close to hatching, at which stage there is a prominent bony ascending process expanded distally into a disk of bone embedded in cartilage. That this entire structure is the astragalus, and not an independent ossification, is confirmed by examining early ostrich and emu embryos[3]; these show that the cartilaginous astragalus is drawn up into an ascending process, as Parker[4] described for the kiwi, and this subsequently ossifies to give the bony ascending process. Ossification commences at the tip of the cartilaginous process, spreads distally and eventually extends across the entire width of the cartilaginous astragalus, as shown in my X rays of juveniles. Ossification of the corresponding process in carinates is confined to the process itself (ref. 1, fig. 2*b*–*e*).

I have examined swan embryos (*Cygnus olor*), and find that the pretibial bone develops as an ossification of a cartilaginous spur, as described for other carinates[1]. Inasmuch as the pretibial bone ossifies separately from the bony calcaneum, my observations[1] do not conflict with those of Martin and Stewart, and I believe that if they examined later stages of swan development they would find that the pretibial bone eventually fused with the calcaneum, as it does in the chicken (ref. 1 fig. 2*f*).

One area of common ground I now share with Martin and Stewart pertains to the homology of the ascending process in ratites and carinates, but our conclusions differ radically. An examination of early duck embryos (days 8–11 of incubation) revealed a dorsal cartilaginous process from the lateral aspect of the astragalus, similar to that seen in early emu embryos (15–20 days)[3]. This early association with the astragalus is soon obscured by the fusion of the cartilaginous astragalus and calcaneum, and from then on the process develops in close association with the calcaneum, as described previously[1]. Similar observations for gulls lead me to believe that the carinate pretibial bone is an astragalar derivative, supporting its homology with the ascending process of ratites.

Ratites, like theropods, have a bony ascending process that is continuous with the astragalus, but carinates have a derived condition where the process fuses with the bony calcaneum. Martin and Stewart deny that the (predominently lateral) carinate pretibial bone is a derived character within birds, noting that the ascending process is laterally placed in the earliest bird, *Archaeopteryx*, but this is the case in theropods[1]; the significant point is not its orientation but whether it is continuous with the astragalus or the calcaneum.



My conclusion that the ratite tarsus is more primitive than that of carinates does, of course, hinge upon theropods being phylogenetically closest to birds, a position I took at the outset with my reference to Ostrom's work[5]. Citing a review by Benton[6], Martin and Stewart point out that pseudosuchians and crocodilians have also been proposed as the nearest avian out-groups. Their own bias for the crocodilian hypothesis is contained in a paper by Martin *et al.*[7]. Note, however, that Walker[8], the leading proponent of the crocodilian hypothesis, has recently reassessed the evidence, concluding that the hypothesis for a common ancestry of crocodiles and birds (above the thecodont level) should be rejected.

I thank H. Lumsden for supplying swan embryos; Dr A. D. Walker for access to his unpublished work; A. J. Baker for reading the manuscript; and the Natural Sciences and Engineering Research Council of Canada for funding support.

The most comprehensive single source of up-to-date authoritative information on today's biotechnology world.

Now *The International Biotechnology Directory* gives you even more data to help you keep right up to date with important developments in this fast moving industry.

- ★ Over 1200 NEW entries
- ★ **NEW full entries** for Australasia and Brazil, plus more information on UK, USA, European countries and Japan.
- ★ Over 950 products and services in Buyers' Guide.
- ★ **NEW journals** More than 100 updates, including changes of prices and addresses, as well as details of new journals and newsletters
- ★ Over 4000 entries for commercial and non-commercial organizations.
- ★ **NEW** comprehensive alphabetical index to directory's unique Buyers' Guide to products, research and services, fully cross referenced to speed access to data.

Moreover, the directory covers both the old established biotechnologies — brewing, food processing, pharmaceuticals and waste treatment — and the new advancing genetic engineering technologies.

Worldwide coverage

The directory covers **all** the countries where the biotechnology industry is most active today: Australia, Austria, Belgium, Brazil, Canada, Denmark, Finland, France, Germany, Greece, Ireland, Israel, Italy, Japan, Netherlands, New Zealand, Norway, Portugal, Spain, Sweden, Switzerland, United Kingdom and the United States

ANALYTICAL METHODS IN HUMAN TOXICOLOGY

edited by A. S. Curry

Part One concentrates on the most recent developments in analytical techniques and equipment. Part Two considers their application to particular poisons and drugs.

Part 1 0 333 34866 4 256pp £35
Part 2 0 333 36882 7 256pp £30

METALLOPROTEINS

edited by P. M. Harrision

Part 1 – Metal Proteins with Redox Roles
0 333 33374 8 272pp £35
Part 2 – Metal Proteins with Non-Redox Roles
0 333 33375 6 352pp £45

Two new volumes in the Topics in Molecular and Structural Biology Series

THE DEVELOPMENT AND EXPLOITATION OF BIRTHWEIGHT STANDARDS

by Roy Carr-Hill and Colin Pritchard

The result of a detailed study, this book suggests methodologies for constructing birthweight standards using a sample population. The results are of widespread clinical importance.

0 333 37297 2 208pp £40

CENTRAL AND PERIPHERAL MECHANISMS OF COLOUR VISION

edited by David Ottoson and S. Zeki

This book puts forward completely new interpretations and theories for the neurophysiological mechanisms of colour vision.

May 0 333 39321 X 350pp £40

THE DETECTION OF NEW ADVERSE DRUG REACTIONS

edited by M. D. B. Stephens

May 0 333 36886 X 240pp £25

DECISION MAKING IN GENERAL PRACTICE

edited by M. Sheldon, J. Brooke and A. Rector

July 0 333 36626 3 208pp £25

GENETIC TOXICOLOGY TESTING

edited by J. M. Parry and C. Arlett

Describes a collaborative study to investigate the mutagenic and carcinogenic properties of a series of "model" chemicals.

July 0 333 38897 6 350pp £40

THE MUSCLE SPINDLE

edited by I. A. Boyd and M. H. Gladden

New research reported in this book will be of great importance to neurophysiologists.

July 0 333 38446 6 £40

THE MANAGEMENT OF AIDS PATIENTS

edited by D. Miller, J. Weber and J. Green

Urgently required information by health professionals everywhere.

In the aftermath

P.M. Kelly

Nuclear Winter: The Human and Environmental Consequences of Nuclear War.
By Mark A. Harwell.
Springer-Verlag: 1984. Pp.179. DM 54.

WITH a fresh spate of books on the "nuclear winter" about to reach the marketplace, it is appropriate that Mark Harwell's sober and detailed account of the biological aspects of the subject should be available first. It deals not only with the effects of a possible nuclear winter but also with the more direct, and inevitable, blast, fire and radiation damage caused by nuclear explosions. The book is based on a technical support document produced, in collaboration with other biologists and ecologists, for the conference "The World After Nuclear War".* It was at this meeting, held in Washington DC in late 1983 and the culmination of a series of exercises designed to assess the scientific validity of the nuclear winter theory, that the first detailed findings concerning the possibility of widespread cooling and concomitant damage to the biosphere were announced.

Shortly after the Washington conference, two summary papers were published in *Science* (**222**, 1,283-1,300). One dealt with the atmospheric component of the theory; the other with the biological aspects. To those aware of developments only through these papers or through brief, sometimes opinionated, accounts in the scientific press and the news media, there seemed to be a lot of fuss about a rather speculative notion. This was a mistaken impression. A great deal of carefully documented background research was available to anyone who cared to look for it, as Harwell's account of the rigorous analysis supporting the biologists' case clearly demonstrates.

But how certain is the atmospheric scientists' case? Since 1983, the principal conclusion of the initial investigators, the *possibility* that a nuclear war would cause a major climatic excursion — an abrupt, marked but short-lived change — has been confirmed by other researchers and by two review projects mounted by the US National Academy of Sciences (NAS) and the Royal Society of Canada (RSC). There are many areas of uncertainty, and the NAS and RSC reports carefully define them, but the *risk* of a nuclear winter now seems undeniable.

The NAS committee concentrated on the atmospheric aspects of the problem, but noted that the impact of the climatic excursion on those who survived the initial effects of a nuclear exchange and on the biosphere as a whole "deserves careful independent study". Progress on the physical side has been rapid since the Washington conference. Many points in the original investigations have been clarified and the computer simulations of the nuclear winter effect have been substantially improved. On the biological side, progress has been slower. In part, this has been an unfortunate by-product of the understandable reluctance of atmospheric scientists to provide the type of detailed information on climate needed for rigorous impact assessment. Computer models of the climatic system tend not to be sufficiently accurate on the spatial and time scales of concern.

One solution to this problem is to use scenarios for possible, in the sense of physically plausible, nuclear winter climates in much the same way as atmospheric scientists assessing the climatic effects use a range of strategically plausible nuclear war scenarios. This is Harwell's philosophy. While concentrating on the consequences of a nuclear exchange in the 5,000 megaton range, the book provides the data necessary to assess the implications of any scale of exchange (or nuclear winter).

Beginning with the development of a nuclear war scenario, which provides the input data for the "consequence analyses", the direct effects of blast, fire and fallout (both local and global) are considered first. This area has been addressed in depth in a number of studies, and Harwell's main contribution is to quantify the impact in terms of casualties and damage to the biosphere in the United States. This section is an excellent introduction to the literature on these aspects of the post-nuclear world. The concept of the nuclear winter is then introduced and a detailed discussion of its effects on the biosphere forms the main part of the rest of the book.

In considering the consequences of the principal assaults — temperature and sunlight reductions, radioactive fallout, and the loss of technical and social support for agriculture — Harwell assesses the net impact on the human population and on the flora and fauna, the food supply for the survivors. Using numerical models whenever available, the impact is quantified in terms of human casualties and food availability. The emphasis is, for the most part, on the northern middle latitude combat zone, and grassland, forest, freshwater and estuarine ecosystems are subject to particular scrutiny. Inevitably, some conclusions are more speculative than others, but the reader is given all the information necessary for a personal assessment of the uncertainties.

In the midst of this description of the gross distortion and near-destruction of the ecology of the combat zone, some surprising insights into possible diets emerge. Ducks, for example, through metabolic generation of heat, could survive temperatures of −40°C for a couple of weeks (in the unlikely event that enough food was available). The analysis ends with a brief section entitled "Recovery Processes". I find the use of the word "recovery" in this context somewhat inappropriate. "Coping" and "adaptation" seem more suitable terms given that many aspects of the pre-nuclear environment (and civilization) might never be recovered.

Harwell also discusses possible psychological responses to the devastation that would occur, but wisely steers clear of dogmatic statements. Similarly, the nature of the fragmented post-nuclear social structure is covered but no firm conclusions are reached. These areas have yet to be considered in any depth but, as the author observes, such factors might well be crucial in determining whether or not use could be made of what limited food supplies would be available. Of particular concern, on the individual level, is the prospect of "psychic numbing" through which unacceptable aspects of reality are shut out and which could severely handicap the ability to survive in the aftermath of nuclear war. Would any form of social organization, whether voluntary or enforced, be possible in such circumstances?

The final section, "Summary of Consequences", is a sobering account of the conclusions of the study: the state of the world after nuclear war. It left one question uppermost in my mind. What can be done to provide viable civil defence and support for those who survived the initial attacks in the face of the multiple hazards of the post-nuclear world?

Harwell's stated intention is "to provide a more comprehensive view of what the world would be like to the immediate survivors of a nuclear war" (p.xv). With the assistance of some (rather harrowing) imaginative effort on the part of the reader, a portrait of the world after nuclear war does indeed emerge from the text. But the main strength of the book lies in the clear, dispassionate accumulation of the technical information needed to assess the implications of the use of nuclear weapons. Harwell has produced an exhaustive, wide-ranging and, in many respects, pioneering treatise, which will be an invaluable reference tool for anyone concerned about nuclear issues. □

*The book resulting from the conference, *The Cold and the Dark*, has been published in paperback in Britain by Sidgwick & Jackson under the title *The Nuclear Winter: The World After Nuclear War* (price £5.95).

Fundamentals of the fourth state

C.N. Lashmore-Davies

Handbook of Plasma Physics, Vols I and II.
Edited by A.A. Galeev and R.N. Sudan.
North-Holland: 1983/1984. Vol. I pp.751, $180.75, Dfl.425. Vol. II pp.850, $190.50, Dfl. 495.

AT A TIME when the growth in the publication of papers on plasma physics shows no sign of slowing, the appearance of two volumes which set out the basic ideas of the subject and provide summaries of all the main lines of research is particularly welcome. These two books are worthy successors to the Leontovich reviews and the Simon and Thompson series, and have the advantage of being published together. They contain 33 articles, 17 of which were contributed by 19 authors from the United States, 15 by 12 authors from the Soviet Union and one by two Japanese authors.

Volume I deals with the principles of plasma physics, and is divided into four parts. The first covers the motion of charged particles in electromagnetic fields, atomic collision processes relevant to plasmas and the various radiation phenomena which can occur in plasmas, concluding with an illuminating discussion of the different modes of description of plasmas for low frequency phenomena and an account of the subtleties of collisional transport in magnetically confined plasmas.

The remaining parts of Vol. I deal with the collective nature of plasmas. An important feature of a plasma is the great variety of waves it can support. The nature of the linearized wave motions allowed by ideal MHD and the effect of allowing for a distribution of particle velocities are both described. Also included are treatments of fluctuations, geometrical optics and the conversion of one linear wave into another in an inhomogeneous plasma.

When there is a reservoir of free energy in a plasma some of these wave modes can become unstable resulting in a great variety of instabilities. The many aspects of plasma instabilities from ideal and resistive MHD, the kinetic instabilities driven by the pressure gradient of a confined plasma, non-thermal particle distributions in velocity space and whether a given instability behaves like an amplifier or an oscillator are all systematically considered. An inevitable consequence of instability is that a plasma moves into a state in which its motion is non-linear. Since a plasma can support so many different wave motions it has been conjectured that a state of weak turbulence might exist, and in the final part of Vol. I the concepts behind this theory are lucidly set forth.

Volume II follows on from its companion, containing Parts 5–9, and is mainly concerned with non-linear consequences. In many practical situations an enhanced level of long wavelength Langmuir waves can be generated (for example by an electron beam or a laser) which, according to weak turbulence theory, should relax to a coherent Langmuir oscillation. The resolution of this apparent paradox and the existence of three-dimensional, localized, high-frequency electric fields are beautifully described by the discoverer of the phenomenon. Also discussed are the spectra resulting from weak turbulence and the numerical modelling of strong Langmuir turbulence.

In hot plasmas the effect of binary collisions is often insufficient to explain various transport processes. The simplest of these phenomena is the dissipation of a current in an unmagnetized plasma, due to the generation of waves rather than inter-particle collisions, although even this apparently simple example is not fully understood. Other examples considered are the dissipation of intense laser light and finite amplitude waves in plasmas through the non-linear generation of waves. Similar but far more complicated situations occur in the cross-field diffusion of particles and energy in magnetically confined plasmas. This complex issue is surveyed, together with an attempt at a comprehensive statistical description of plasma turbulence. These effects are generally referred to as anomalous although in many applications they represent the normal situation rather than the exception.

Part 8 consists of two excellent reviews on the diagnostic methods upon which the subject of plasma physics rests; the first is concerned with radiative techniques and the second with the methods used in hot magnetically confined plasmas, complementing those discussed in the first article. Volume II also contains an informative account of the methods of particle simulation by computer and a thorough discussion of the equilibrium and stability of non-neutral relativistic electron beams and their interaction with plasma.

Together, the books satisfy the aims of the general editors in encompassing most of the present-day knowledge of plasma physics, albeit from a user point of view. They are not suitable for someone requiring an introduction to the subject; although they take the reader to the frontiers of current research, they do not cover the general topic of the foundations of plasma kinetic theory nor do they contain more than a very brief account of the fundamental and fascinating subject of Landau damping. But those actively involved in research on plasma physics will find these volumes invaluable, as will experienced workers in other fields wishing to acquaint themselves with a particular aspect of the subject. □

Off the record

John Parkington

From Hunters to Farmers: The Causes and Consequences of Food Production in Africa.
Edited by J. Desmond Clark and Steven A. Brandt.
University of California Press: 1984. Pp.433. $63.25, £52.25.

AFRICA, as one of my mentors once sagely remarked, is a very big place. It encompasses environments as diverse as the sand seas of the Sahara and Namib, the thirstlands of the Kalahari and Sahel, the heath communities of the Cape and Mahgreb, the savannahs of Serengeti and the tropical forests of Zaire. To understand the social and ecological events leading to and following from the transition from food gathering to food production over such a vast and varied area is a Herculean task. Yet archaeologists are nothing if not optimists, and the goal of *From Hunters to Farmers* is nothing less than this. A collection of 30 papers, it sets out to provide a synthesis of current knowledge and is, in effect, the published proceedings of a symposium held in Los Angeles in 1978.

The volume is divided into four sections, the first consisting of three general papers which present a depressing but honest picture of how little we know about past climates, past population distributions and the circumstances surrounding the adoption of food production in Africa. Most of the contributions fall into the second section and are regional summaries of greater or lesser geographical scope. I wondered at this point what distinguishes papers that are quoted long after publication. Do they contain dazzling theoretical insights or essential primary observations? Or do they reflect the spirit of their times? Regional reconstructions based on modest but accumulating data sets are almost by definition transitory phenomena. We all write and then rewrite them.

To my mind the most interesting section is the third, in which the effects of the acquisition of domestic plants and animals by Kalahari San are documented. These three papers combine empirical observations with theoretical perspectives and will probably have longer lives than the regional accounts. Because they contribute to the realization that the San are, and have been, far from isolated from agriculturalists and pastoralists, they will have immediate im-

New in paperback

pact. The only paper in the fourth section describes the difficulties involved in palaeodemographic reconstruction and provides a good overview of what we would like to know but usually find hard to document archaeologically.

As the editors undoubtedly expected, this book is more valuable in what it shows up rather than what it shows off. The contributors have demonstrated that we know very little of the climatic and environmental circumstances that preceded the appearance of domesticates, that the preservation of reasonable samples of plants and animal bones in archaeological contexts is variable but generally poor, that we have very inadequate dating of critical changes, and that models for understanding *how* and *why* people shift into agriculture or pastoralism are only now emerging. More seriously we see an archaeological record that is so residual and fragmentary that it becomes malleable and an easy victim for a predatory hypothesis. In these circumstances it is extremely tempting to "fit" the archaeological evidence onto superficially more substantial linguistic histories, climatic reconstructions or, more commonly, ethnographic models.

Several of the contributors (particularly but not only Stahl, Ambrose, Klein, Gifford-Gonzalez, and McIntosh and McIntosh) make the point that archaeological observations have to generate some internal and independent consistency. This comes only from sustained multidisciplinary research into regional sequences of events, something that few parts of Africa have so far enjoyed. What is known is largely in this book. Although I would liked to have read more discussion of theory and method, to have seen more concern with social than ecological issues and to have heard more talk of process, I recognize and recommend here a valuable summary of our current understanding of "the causes and consequences of food production in Africa". □

John Parkington is in the Department of Archaeology at the University of Cape Town.

Search for hay in a needlestack

Harry Hertz

Organic Trace Analysis.
By K. Beyermann.
Ellis Horwood/Halsted: 1984. Pp.365. £35, $74.95.

THE search for trace organic substances in complex inorganic and organic matrices is one of the most challenging problems facing chemists. It pervades all aspects of our lives: the water we drink, the food we eat, the environment in which we work and live, the quality of our manufactured goods and many aspects of our day-to-day health. Klaus Beyermann's *Organic Trace Analysis*, a generally very readable translation of the original German edition, is the first comprehensive description of this developing field of analytical chemistry.

Beyermann has aimed the treatise at a diverse audience, from the professional analyst to "science administrators, biologists, politicians [and] forensic experts". While this is an admirable goal, it has led to occasional identity crises and uneven presentation of various topics. Nevertheless, if readers are willing to pick and choose what to read they will find that the book does present an effective overview of the field.

An outstanding feature is the references, some 3,000 of them. Much of the information on previous studies is reported in tables, permitting easy access to the literature. Furthermore, all the tabular entries (as well as the text itself) are extremely well indexed in the back of the book, making this an outstanding rapid-reference volume. The order of presentation follows the logical sequence of analysis: from general aspects through sampling, sample handling, component separations and detection.

There are, however, some flaws. The book as a whole is less evaluative of the literature than one would like, the author usually choosing to cite relevant works without any commentary. Section 2.4, which deals mainly with statistics, was not contributed by Beyermann and is not as well written as the rest of the book. The level of detail in this introductory section is perhaps excessive, while the references here are more parochial than they are elsewhere; this could dissuade some readers from continuing. And the topic of sampling and storage is treated in a manner which belies the problem in this area of assuring analyses which accurately represent the native (*in situ*) concentration of the species of interest.

As with any rapidly evolving field, by the time a book has been through the publication mill new discoveries have appeared and contributed to the science being discussed. Here consideration of such techniques as fast atom bombardment in mass spectrometry and the impact of monoclonal antibodies on immunoassay is not included, and thus the book already has a somewhat dated look in parts. For all that, the publication of *Organic Trace Analysis* is undoubtedly a milestone in analytical chemistry. It is a handy reference volume for the practising analyst and a valuable introduction for the generalist who is prepared selectively to read sections of the book. □

Harry Hertz is Director of the Center for Analytical Chemistry at the US National Bureau of Standards, Gaithersburg, Maryland.

Angles on aphids

M. Llewellyn

Aphid Ecology.
By A.F.G. Dixon.
Blackie/Methuen: 1985. Pp.157. £17.95, $39.95.

APHIDS are specialist phloem-feeding insects that have received world-wide attention, both because of their importance as agricultural pests and because of the intricacy and diversity of their biology. A book on aphid ecology by a leading research worker in both fields will thus attract attention from a number of angles. Satisfying all potential readers — especially in a mere 136 pages of text — is a tall order, but Professor Dixon has succeeded remarkably well.

This book is as much about the biochemistry, physiology, genetics and evolution of aphids as about patterns and processes of ecology; it contains not only information about a specialist taxon of insects but constitutes an integrated approach to ecology which, although often talked about, is rarely attempted. Many areas are excellently reviewed. The accounts of such topics as "galling", polymorphism, genetic change, sexual morph production and host-alternation are a delight, and a large literature on the population dynamics of several species has been crystallized into a fascinating and informative chapter. A few subjects do not catch the imagination, however; the section on host plant finding and nutrition, for example, is not particularly convincing. The book is peppered with the author's own ideas and theories — on aphid size, ovariole number, reproductive strategies and the aphid fauna of the tropics — which may not find universal approval but which will stimulate the work of aphid biologists for some time to come.

There are well over 100 graphical figures, as befits an experimental, quantitative approach to ecology, but I often found them of little value because of the lack of adequate background information. The condensed treatment of some topics, in particular reproductive strategies and aspects of migration, may baffle the general reader, and it is a pity that the space taken by some figures was not used to extend consideration of difficult concepts such as these.

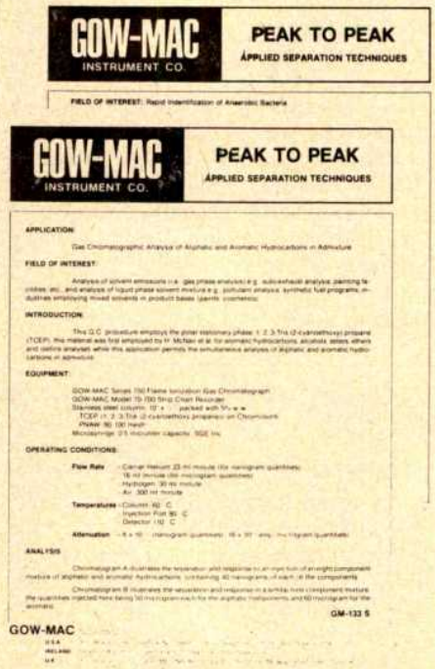
After reading this book few will disagree that a broad approach to ecology, drawing upon diverse areas of biology, is anything other than desirable. Here it has resulted in a challenging text which surely heralds the demise of the specialist and blinkered approach to ecology so prevalent over the past 30 years. □

M. Llewellyn is a Lecturer in the Department of Biology at Queen Elizabeth College, University of London.

Forensics and receptor binding

Forensic drug analysis is covered in a new data sheet and a new system simplifies receptor binding assays.

● Latest option for EG&G Ortec's System 5000 energy dispersive spectrometer is the Model 5165 system for digital beam control and X-ray colour mapping. The Model 5165 allows the System 5000 to store and display up to 12 elemental maps of data acquired from an energy dispersive X-ray spectrometer connected to an electron microscope. All 12 maps plus a histogram and an expanded display of one of the maps may be displayed simultaneously.
Reader Service No. 100.

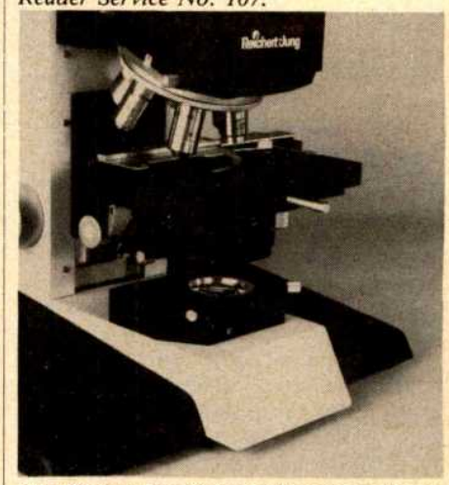


● Two new polymeric ion-exchange columns have been developed by Interaction Chemicals Inc. for the separation of peptides that are difficult or impossible to separate using silica-based columns. Column efficiencies approach 100,000 plates per metre. The BIO-10 column contains a low capacity material particularly suited for separation of acidic peptides. The BIO-20 column contains a low capacity polymer that will easily separate basic peptides using low ionic strength eluents at elevated *p*H values. Acidic peptides are not retained on this column, so group separations are readily accomplished. Both polymers are stable from *p*H 0 to 15 and can be used with most aqueous eluents.
Reader Service No. 101.

The Model 9600 from Eldex.

● The Eldex Model 9600 is an integrated, programmable solvent delivery system designed for applications ranging from microbore HPLC separations to high-resolution preparative scale purification. The Model 9600 is designed to generate ternary gradients with pulse-free solvent delivery and is fitted ports for interfacing with other chromatography peripherals.
Reader Service No. 102.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Service Card bound inside the journal.



● Four new data sheets from Gow-Mac cover novel topics. One discusses "Forensic and Analytical Toxicological Drug Analysis", the second discusses other "Analytical and Toxicological Drug Analysis" the third discusses "Forensic Toxicology", and the fourth discusses a new instrument, the 740-770P series of gas chromotographs. To receive copies of these data sheets and a list of others available use the Reader Service Card.
Reader Service No. 103.

● Miles Scientific offers six monoclonal antibodies to four major groups of proteins: collagen Type IV, laminin, keratin sulphate and proteoglycan. (Three antibodies directed to three types of chondroitin sulphate stubs remaining after chondroitinase ABC digestion.) All antibodies are broadly species reactive except collagen Type IV, which appears specific for human tissue and cells only.
Reader Service No. 104.

● Receptor binding assays are simplified by a new system from Skatron based on the Skatron Cell Harvester. Operation of the instrument involves simultaneous filtration (under reduced pressure) of twelve incubation samples suitably held in Macrowell tubes. A specially designed suction unit head effectively washes the contents of the tubes onto a suitable filter paper — Skatron recommends glass-fibre filter catalogue no. 7034. The Skatron Filterpunch transfers the disks of filter material, six at a time, directly into scintillation vials.
Reader Service No. 105.

● Now available from Genzyme Corporation for use in glycoprotein research is *N*-glycanase (peptide *N*-glycosidase F). The ultrapure enzyme cleaves all asparagine-linked glycan chains from glycoproteins to yield a carbohydrate-free polypeptide and oligosaccharides with the reducing end of their chitobiose cores intact. The enzyme preparation is also completely free of proteases and other endo- or exoglycosidase activities. The purity and broad specificity for complex, hybrid and high-mannose oligosaccharide structures makes the enzyme useful for structural and functional studies of the sugar and polypeptide portions of glycoproteins.
Reader Service No. 106.

● A new Biorad cation exchange HPLC column offers high resolution, high sample loads and high recoveries of biologically active proteins and peptides. Called Bio-Gel TSK SP-5PW, the new resin-based column can operate in the *p*H range 2-12. Either acid (0.1M HCl) or base (0.1M NaOH) washes may be used to clean the column. Pore size is 1,000Å, so the SP-5PW matrix can separate proteins with molecular weights as high as one million with no loss of capacity, resolution or column life. Loading capacity is in the range 1-5 mg for the protein of interest.
Reader Service No. 107.

The Reichert-Jung Polyvar with new condenser.

● A new condenser for the Reichert-Jung Polyvar photomicroscope overcomes the difficulties inherent in illuminating very large fields at different magnifications. Instead of having to re-arrange the optical elements in the condenser and adjust the aperture and field size to accommodate the objectives being used, the operator can utilize the widefield condenser 0.90/0.32 NA system to provide uniform illumination within a broad magnification range.
Reader Service No. 108.

FOUR DYNAMITE REASONS WHY YOU SHOULD SUBSCRIBE TO BIO/TECHNOLOGY NOW . . .

1 ■ You'll save time. Because you don't have time to read every journal in the field, BIO/TECHNOLOGY is written and edited to give you all the information you need in ONE convenient source. BIO/TECHNOLOGY is the only journal to give you news. Features. Original research. Product evaluations. Industrial applications. Job openings. Book and product reviews. And more. If it's important to your work, you'll find it between the covers of BIO/TECHNOLOGY.

2 ■ You'll learn new ways to improve your on-the-job skills and run a more successful operation. Each month BIO/TECHNOLOGY gives you the scoop on invaluable start-up information . . . the latest instrumentation . . . marketing breakthroughs . . . funding sources . . . new technologies . . . patents and licences . . . profiles on how others are avoiding the pitfalls and reaping the rewards. In fact, just one practical tip from BIO/TECHNOLOGY can be worth many times the cost of your subscription.

3 ■ You'll be up-to-date on all major industry developments. With correspondents all over the world, BIO/TECHNOLOGY delivers the inside story on who's doing what, where. You'll get the latest word on changing government regulations and tax law, and how they affect your work.

Plus you'll read original research papers by bench scientists, engineers, and biologists that will help keep you in the forefront of every new discovery worth knowing about.

4 ■ You'll get new ideas you can put to use immediately. BIO/TECHNOLOGY lets you rub elbows with eminent scientists, tour new facilities and learn how new processes work in every field from genetic engineering to molecular biology. Each month, BIO/TECHNOLOGY helps spark ideas for your own research, for new industrial applications and for getting along in the increasingly competitive financial arena.

If you're not already subscribing to BIO/TECHNOLOGY, don't delay the moment any longer - return the coupon below and we will send you twelve issues. You risk nothing If for any reason BIO/TECHNOLOGY doesn't live up to your highest expectations, just let us know and you'll receive a full refund on all unmailed copies. Remember too, that your subscription may be tax deductible.

TO START RECEIVING YOUR SUBSCRIPTION, FILL OUT THE COUPON BELOW AND RETURN WITH PAYMENT TO:

Postgraduate Medical Journal

Journal of The Fellowship of Postgraduate Medicine

* a monthly compendium of current clinical research and practice
* review articles contain extensive up-to-date bibliographies as guides to further reading
* publishes single subject symposia written by specialists within that discipline
* surveys and reports on clinical problems of particular interest
* correspondence, Book Reviews, Conference Proceedings, and Diary of Forthcoming Events

The essential combination – invaluable to the Medical Postgraduate

MACMILLAN PRESS Ltd
SCIENTIFIC & MEDICAL

May meetings

14–16 May 1985, **International Conference and Exhibition on Biotechnology**, Boston, USA (B. Burris, Cahners Exposition Group, 7315 Wisconsin Avenue, PO Box 70007, Washington, DC 20088, USA).
14–17 May 1985, **International Society for Neurochemistry Symposium on Exitatory Amino Acids**, Bournemouth, England (Dr P.J. Roberts, Department of Physiology and Pharmocology, University of Southampton, Southampton SO9 3TU, UK).
21–24 May 1985, **Conference on Lasers and Electro-optics**, Maryland, USA (Optical Society of America, 1816 Jefferson Place, N.W. Washington, DC 20036, USA).
22–24 May 1985, **International Congress on Tissue Integration in Oral and Maxillo-Facial Reconstruction**, Brussels, Belgium (Prof. D. van Steenberghe, Dept. of Periodontology, Faculty of Medicine, Catholic University Leuven, Kapucijnenvoer 7, B-3000 Leuven, Belgium).
24–25 May 1985, **International Meeting on Genetic Polymorphism and Fertility in Mammals**, Rome, Italy (Prof. G. Montalenti, Accademia dei Lincei).

June meetings

3–6 June 1985, **Karlsruhe International Conference on Analytical Chemistry in Nuclear Technology**, Karlsruhe, FRG (Prof. Dr Hans J. Ache, Kemforschungszentrum Karlsruhe GmbH, Institut fur Radiochemie. Postfach 3640, D-7500 Karlsruhe 1, FRG).
4–6 June 1985, **Symposium on Artificial Intelligence**, COGNITIVA 85, Paris, France (Marie-France Chicanne, CESTA, 1 rue Descartes 75005 Paris, France).
6–8 June 1985, **International Conference on Biological Reactive Intermediates**, University of Maryland, USA (Dr R. Snyder, Dept. of Pharmocology and Toxicology, College of Pharmacy, Rutgers University, Piscataway, NJ 08854, USA).
10–14 June 1985, **International Conference on Computers in Chemical Research and Education**, Oberbayern, Germany (Dr J. Brandt, Institut Für Organische Chemie, Technische Universität München, Lichtenbergstr. 4, D-8046 Garching, FRG).
14 June 1985, **International Seminar on Immunopathology of Rheumatic Diseases**, Montpellier, France (Prof. J. Sany, Service d'Immuno-Rhumatologie et Readaption Fonctionelle, Centre Gue-de-Chauliac, Hôpital Saint-Eloi, 34059 Montpelier, France)
17–20 June 1985, **International Conference on Developments in Analytical methods in the Pharmaceutical and Biomedical Sciences**, Camerino, Italy (Prof. I. Antonini, University of Camerino, 62032 Camerino, Italy).
19–21 June, **International Symposium on Molecular Aspects of Neurobiology**, Florence, Italy (Dr E. Folco, Fondazione Giovanni Lorenzi, Via Montenapoleone, 23-20121 Milan, Italy).
23–27 June 1985, **International Conference on Modern Trends in Activation Analysis**, Copenhagen, Denmark (Dr K. Heydom, Riso National Laboratory, Postbox 49, Dk-4000, Roskilde, Denmark).
25–28 June 1985, **International Conference on Surface Engineering**, Brighton, UK (The Conference Office, The Welding Institute, Abington Hall, Abington, Cambridge CB1 6AL, UK).
26–28 June 1985, **International Congress on Lasers in Medicine and Surgery**, Bologna, Italy (Medicina Viva, Viale dei Mille, 140 43100 Parma, Italy).

July meetings

30 June–5 July, **International Conference on Proteins of Iron Metabolism**, Villeneuve d'Ascq, France (Prof. G. Spik, Universite des Sciences at Techniques de Lille I, Laboratoire de Chimie Biologique, F-59665 Villenueve d'Ascq Cedex France).
1–3 July 1985, **International Symposium on Physico-Chemical Properties and their Role in Environmental Hazard Assessment**, Canterbury, UK (H.L. Bennister, 174 Beverley Drive, Edgeware, Middlesex HA8 5ND, UK).
2–5 July 1985, **International Conference on Improving University Teaching**, Utrecht, The Netherlands (T.B. Massey, The University of Maryland University College, College Park, MD 20742, USA).
7–11 July 1985, **International Symposium for Comparative Research on Leukemia and Related Diseases**, Hamburg, Germany (Prof. F. Deinhardt, Max v. Pettenkofer Institut, Pettenkoferstr. 9a, D-8000, Muenchen 2, FRG).
7–12 July 1985, **International Conference on Natural Products**, North Carolina, USA (Prof. D.G. Kingston, Dept. of Chemistry, Virginia Polytechnic Institute and State University, Blacksburg, VA 24061, USA).
7–12 July 1985, **International Conference Ion Beam Analysis**, Berlin, FRG (IBA'85, HMI Berlin, Postfach 39 01 28, D-1000 Berlin 39, FRG).
7–10 July 1985, **International Congress on Engineering and Food**, Alberta, Canada (ICEF-4 Dept. of Food Sciences, University of Alberta, Edmonton, Alberta, Canada T6G 2PF).
8–12 July 185, **International Meeting on NMR Spectroscopy**, Cambridge, UK (Dr J. Gibson, Secretary (Scientific), The Royal Society of Chemistry, Burlington House, London W1V 0BN, UK).
8–12 July 1985, **International Symposium on Controlled Release of Bioactive Materials**, Geneva, Switzerland (USA: CRS Administrative Office, 16 Nottingham Drive, Lincolnshire, IL 60015 312/945-1616. Europe: Symporg S.A. P.O. Box 76, CH-1222, Vesenaz-Geneva, Switzerland 022-524-104).

Please send 'Announcements' entries to:
The Editor, Nature,
4 Little Essex Street,
London WC2R 3LF, UK

August meetings

3–8 August 1985, **International Leukocyte Culture Conference** to be held jointly with the National Meeting of the Reticuloendothelial Society, Ithaca, New York, USA Awards of up to $500 will be made for papers, on the basis of scientific merit. There will also be an award of $500 for the winning presentation (RES/LCC Conference Office, Dr Sherwood M. Reichard, Medical College of Georgia, Augusta, Georgia 30912, USA).
11–17 August 1985, **International Anatomical Congress and Exhibition**, Barbican Centre, London, UK (IAC Secretariat, 100 Park Road, London NW1 4RN, UK).
12–14 August 1985, **Symposium on the Ethics of Animal Experimentation**, Stockholm, Sweden (M. Thelestam, Dept. of Bacteriology, Karolinska Institutet, S-104 01 Stockholm, Sweden).
18–21 August 1985, **International Symposium on Order in the Amorphous State of Polymers**, Midland, Michigan, USA (S. Butler, Symposium Secretary, MMI, 1910 West St. Andrews Road, Midland, Michigan 48640, USA).
21–24 August 1985, **International Meeting on Metallothionein and other Low Molecular Weight Metal-binding Proteins**, Zurich, Switzerland (Prof. J.H.R. Kagi, Institute of Biochemistry, University of Zurich, Winterthurerstrasse 190, CH-8057 Zurich, Switzerland).
25–30 August 1985, **IUPAP Nuclear Physics Conference**, Harrogate, UK (The Institute of Physics, 47 Belgrave Square, London SW1X 8QX, UK).
26–30 August 1985, **International Symposium on Nuclear Medicine and Related Medical Applications of Nuclear Techniques in Developing Countries**, Vienna, Austria (Int. Atomic Energy Agency, IAEA-SM-283, Vienna International Centre, PO Box 100 a 1400 Vienna, Austria).
29–31 August 1985, **20th Meeting of the European Association for the Study of the Liver**, Helsinki, Finland (EASL, The Finnish Medical Society Duodecim, Mrs Leena Antikainen, Runeberginkatu 47 A, SF-00260 Helsinki, Finland).

September meetings

2–6 September 1985, **International Symposium on Marine Natural Products**, Paris, France (Drs A. Ahond and C. Poupat, ICSN du CNRS, 91190 Gif s/Yvette France).
2–7 September 1985, **European Drosophila Research Conference**, Balatonszeplak, Hungary (J. Szabad, Institute of Genetics, Biological Research Center, H-6701 Szeged, Hungary).
3–5 September 1985, **Symposium of the**

Uranium Institute, London, UK (Symposium Secretariat, Conference Associates UIS, 27A Medway Street, London SW1P 2BD, UK).

3–6 September 1985, **Noordwijkerhout Symposium on Innovative Approaches in Drug Research**, Noordnijkerhout, The Netherlands (Dr J.F. Rodrigues de Miranda, c/o Prof. Dr H. Timmerman, Vrije Universiteit, Department of Pharmocochemistry, De Boelelaan 1083, 1081 HV Amsterdam, The Netherlands).

3–6 September 1985, **European Nuclear Medicine Congress**, London, UK (European Nuclear Medicine Congress 1985, Institute of Nuclear Medicine, Middlesex Hospital Medical School, Mortimer Street, London W1N 8AA, UK).

8–13 September 1985, **International Congress of Pure and Applied Chemistry**, Manchester, UK (Dr J.F. Gibson 30th IUPAC Congress, Royal Society of Chemistry, Burlington House, London W1V 0BN, UK).

8–13 September 1985, **European Immunology meeting**, Jerusalem, Israel (Prof. M. Schlesinger, Secretariat of the 7th Immunology Meeting, PO Box 983, Jerusalem 91009, Israel).

9–13 September 1985, **IUPAC International Congress of Pure and Applied Chemistry**, Manchester, UK (Dr J. Gibson, 30th IUPAC Congress, Royal Society of Chemistry, Burlington House, London W1V 0BN, UK).

3 Sept–4 October 1985, **International Remote Sensing Workshop**, South Dakota, (US Geological Survey, 917 National Center, Reston, VA 22092, USA).

8–13 September 1985, **International Conference on Biothermodynamics**, Styria, Austria (Dr P. Laggner, Institut für Röntgenfeinstrukturforschung, der Österreicheischen Akademie der Wissenschaften und des Forschungszentrums, Graz, Austria).

8–13 September 1985, **Laurentian Hormone Conference**, Alberta, Canada (The Laurentian Hormone Conference, 45 Shattuck Street, Boston, MA 02115, USA).

9–10 September 1985, **International Symposium on Drug Analysis: Current Challenges**, Ottawa, Canada (Dr G.L. Mattok, Bureau of Drug Research, Health Protection Branch, Tunney's Pasture, Ottawa, Ontario, Canada K1A 0L2).

9–14 September 1985, **International Conference on Magnetospheric Systems**, Toulouse, France (Centre National d'Études Spatiales, Department des Affaries Universitaires, 18 avenue Édouard-Belin, 31055 Toulouse, France).

Appointments

Dr Archie Johnston (director of the Health and Safety Executive's Reseach and Laboratory Services Division) has been appointed to the Health and Safety Executive to make up the three man team. The executive is responsible for implementing the provisions of the health and Safety at Work Act 1984.

Professor John L. Jinks has been appointed to be Secretary and Deputy Chairman to the Agricultural and Research Council from 1 May 1985. He has been chairman of the council's plants and soils research committee for the past two years.

Dr Jo Eirik Asvall has been appointed Regional Director for Europe of the World Health Organization (WHO). For the past six years Dr Asvall has been Director of Programme Management at the WHO Regional Office for Europe.

Sir Francis Tombs is to become chairman of The Engineering Council on 1 May 1985 for a three-year period. Sir Francis is a past president of the Institution of Electrical Engineers.

Mr John Webb (managing director of Bayer Limited) has been appointed Chairman of the Chemical Industry Safety, Health and Environment Council (CISHEC), the body responsible for the UK chemical industry's position on health, safety and the environment.

Dr Ronald S. Paul has been elected Chief Executive Officer of the Batelle Memorial Institute having been president and Chief Operating Officer for the past three years.

Awards

Dr D.A. Henderson, who led the global campaign that successfully eradicated smallpox, has been awarded the Albert Schweitzer International Prize for medicine by the Burroughs Wellcome Fund (supported by the Burroughs Wellcome Company). Dr Henderson is dean of The John Hopkins School of Public Health, Baltimore, Maryland.

Loughborough University is to confer the honorary degree of Doctor of Technology on Olympic gold medallist and world record breaking athlete **Sebastian Coe**. Coe has a BSc degree in Economics from Loughborough, where he was an undergraduate, research student and research assistant. It is hoped that the ceremony will take place in July this year.

750 Overseas Research Students (ORS) Awards will be offered on a competitive basis in 1985 to overseas postgraduate students. The scheme is administered by the Committee of Vice-chancellors and Principals of the universities of the United Kingdom. Each award will cover the difference between the tuition fee for a home postgraduate student and the "full-cost" fee chargeable to an overseas postgraduate student. Candidates must be overseas graduate students who, in session 1985-86, are commencing full time study as registered research students for a higher degree at one of the academic institutions participating, or are already on such a course and do not have an ORS award. Awards may be held in any field of study by students of outstanding merit and research potential. Further details and application forms from the registrar of any of the academic institutions taking part in the scheme, including Aberdeen, Leeds and Sussex Universities.

The Simon Fraser University, Canada, announces the R.H. Wright award in Olfactory Research of $25,000. The award will be made to an individual who has recorded outstanding achievements in research in olfaction. Names of proposed candidates and supporting information should be sent to B.F. Clayman, Simon Fraser University, Burnaby, British Columbia V5A 1S6, Canada.

The European Science Foundation is offering short and long term research fellowships in toxicology. Fellowships can be awarded to applicants of any nationality working in any field of the natural and life sciences, provided that their project contributes to furthering research in toxicology within Europe. The deadline for submitting completed applications is 30 September 1985, and application forms may be obtained from: ESF Research Fellowships in Toxicology (PGT), Dr John Smith, European Space Foundation, 1 quai Lezay-Marnesia - F - 67000 Strasbourg, France.

The British Ecological Society is offering grants ranging from £50 to £500 to amateur and professional scientists undertaking ecological research and survey, usually within the United Kingdom, but grants are also given to projects abroad. Application forms are available from the British Ecological Society (S.E.P.G.), Burlington House, Piccadilly, London W1V 0LQ. Further details from Dr M.B. Usher, Department of Biology, University of York, York YO1 5DD.

The Gerontological Society of America invites nominations for its 1985 Brookdale Awards for distinguished contributions to gerontology. Three awards of a $25,000 cash prize will be given to gerontologists recognized nationally and internationally in their field, two of whom will be US citizens and one a non-US citizen. Further details from Linda Harootyan, The Gerontological Society of America, 1411K St, NW, Suite 300, Washington, DC 20005.

Miscellaneous

Columbia University chemical engineer **Helmut W. Schulz**, at 72, has won official recognition for a 44-year old idea that was long wrapped in military secrecy. The US government has awarded him $100,000 in recognition of an innovative proposal he made as a young man for an energy efficient gas centrifuge method of uranium enrichment. This is the largest sum ever granted for an invention put under military wraps and thus unavailable for use by its inventor. □

THE INSTITUTE OF CANCER RESEARCH

TECHNICIAN

required for cell biology laboratory at The Institute of Cancer Research, Sutton, Surrey, to investigate the mechanisms of cell killing by cytotoxic drugs and radiation. Previous experience in tissue culture, cell fractionation and basic biochemical techniques would be an advantage. However, further training will be given.

Salary will be in the range of £5,738 — £7,159 per annum depending on qualificatons and experience + £623 London Allowance pa.

Applicants are advised that in the majority of the Institute's premises smoking is prohibited.

Applications in duplicate with the names and addresses of two referees should be sent to the Personnel Officer, Institute of Cancer Research, 17A Onslow Gardens, London SW7 3AL, quoting reference 301/B/85. (6370)A

UNIVERSITY OF LEEDS

DEPARTMENT OF IMMUNOLOGY

LECTURER

Applicants are invited for the above post, which is situated within the Leeds General Infirmary available from 1 October 1985.

Applicants must have a PhD and at least five years post-doctoral experience, together with three years teaching experience including formal lectures to undergraduates.

Informal enquiries may be made to Professor Gowland (Tel (0532) 432799 ext 3540).

Salary on the academic scale for Lecturers (£7,520 — £14,925)(under review) according to age, qualifications and experience.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference no. 91/3. Closing date for applications 6 June 1985. (6341)A

UNIVERSITY OF NOTTINGHAM

DEPARTMENTS OF BIOCHEMISTRY AND SURGERY

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the above post on a project funded by the Cancer Research Campaign to investigate biochemical and immunochemical aspects of glycoproteins produced by primary human breast cancers. The work will be carried out primarily in the Department of Biochemistry in close collaboration with Professor Blamey of the Department of Surgery. Initial salary will be at the first or second point on Range 1A for Research and Analogous Staff, depending on qualifications and experience.

Applications including a curriculum vitae and names of two referees should be submitted by May 17th to Professor F W Hemming, Department of Biochemistry, Queen's Medical Centre, Nottingham NG7 2UH (0602 700111 ext. 3619). (6356)A

MEDICAL RESEARCH COUNCIL

MRC Tuberculosis and Related Infections Unit at the Hammersmith Hospital, London W12 OHS.

POSTDOCTORAL MOLECULAR BIOLOGIST

is required to work in a team engaged in the study of structure and function of protein antigens of mycobacteria. Background experience in recombinant DNA and/or peptide technologies is desirable. The appointment is for a period of 3 years with a possibility of extension up to 5 years, starting from September 1985.

Remuneration will be based on the University non-clinical academic staff scales. Applications with curriculum vitae, list of publications, names of two referees and a brief summary of current research interests should be submitted to the Director of the Unit, Dr. J. Ivanyi (address above, phone 01-743-4594, Ext 60). (6334)A

COMPUTER PROGRAMMER/ ANALYST

The ICI Corporate Bioscience Group has an opportunity for a computer programmer/analyst to lead the development of computing facilities for the group to support research in molecular genetics, plant sciences and cellular biology.

The successful applicant (male/female) will interact closely with Bioscience Group scientists to analyse their computing requirements, develop suitable software for use on DEC VAX 11/780 or microcomputers, and will also advise on the acquisition of hardware and software and ensure its integration into the group's work.

Candidates should have a degree (or equivalent) in computer science, physical science or related subject and at least two year's full-time computing experience in a scientific environment. Familiarity with the use of 8086-based microcomputers is desirable and a knowledge of biochemistry or chemistry would be an advantage.

The vacancy is in the laboratories of a large science community located at Runcorn Heath in Cheshire. You would be a member of a Mond Division team which provides specialist support to the various groups on the site.

A competitive starting salary dependent on age and experience will be offered. Conditions of employment are excellent. Relocation assistance is available where applicable.

For an application form contact Sue Owen on Runcorn (0928) 513712 or write to:-
Mrs S Owen,
Personnel Department,
Imperial Chemical Industries plc,
PO Box 8, The Heath,
Runcorn, Cheshire
WA7 4QD.

(6405)A

ICI

UNIVERSITY OF BRADFORD

Chair in Environmental Science

Applications for the Chair are invited from candidates with experience in the Schools' range of academic activities which currently include animal and plant ecology, land use economics, environmental management, human geography, pollution chemistry, and occupational hygiene

The Professor will be expected to give an overall lead to research and teaching, as well as contributing within his/her own subject area(s)

Further particulars can be obtained from the Registrar and Secretary, University of Bradford, West Yorkshire, BD7 1DP.

Closing date for receipt of applications is Friday, 7th June, 1985. (6337)A

DURHAM UNIVERSITY

DEPARTMENT OF GEOLOGICAL SCIENCES

Applications are invited for a

LECTURESHIP IN GEOPHYSICS

tenable in any area of solid-earth geophysics, but with some preference for candidates in marine geophysics or seismology.

Applicants must have previous research experience in geophysics. It is hoped to fill the post from not later than 1 October 1985. Salaries on the scale £7,520-£14,925 per annum with superannuation.

Application (3 copies) naming three referees should be sent by 31 May 1985 to the Registrar, Science Laboratories, South Road, Durham DH1 3LE. From whom further particulars may be obtained.

(6367)A

DIRECTOR

LUDWIG INSTITUTE FOR CANCER RESEARCH BRANCH OF MONTREAL

The Ludwig Institute for Cancer Research is seeking an outstanding scientist to direct the research program of its proposed Branch in the field of cancer genetics encompassing the latest developments in such areas as cell biology, biochemistry and molecular biology. The Ludwig Institute is creating a new Branch which will conduct its research in Montreal, Quebec, in conjunction with the Royal Victoria Hospital and in association with McGill University. University and hospital academic appointment of an appropriately qualified candidate is anticipated. Planning cells for the Branch to occupy space exceeding 12,000 sq. ft.

Candidates must have demonstrated outstanding research capabilities, both in their own personal research and in attracting and leading excellent younger investigators. A Director will be a leader in basic science (Ph.D. and/or M.D) and will have an associate staff member who will lead the clinical investigative activities. Interested candidates should submit an up-to-date curriculum vitae and bibliography, about five selected recent reprints, and names of three internationally known referees no later than July 1st, 1985 to: **Dr. Lloyd Old, Scientific Director, Ludwig Institute for Cancer Research, Stadelhofer-sdtrasse No. 22, 8001 Zurich; Switzerland.**

Priority will be given to Canadian citizens and permanent residents.

(NW1736)A

DEPARTMENT HEAD EPIDEMIOLOGY/BIOSTATISTICS

The Hospital for Sick Children, one of North America's leading paediatric centres with a strong research focus, and affiliated with the University of Toronto, is establishing a Department of Epidemiology/Biostatistics, and is presently seeking a Department Head. It is planned to establish a "core" department to which other individuals in the Hospital with substantial epidemiology/biostatistical interests will relate Cross appointments in the Department of Preventative Medicine and Biostatistics in the University of Toronto are anticipated.

The preferred candidates will have clinical training (MD) as well as epidemiological training, with sufficient experience to undertake the responsibility of developing and administering a hospital department involved in research, consultation, service and teaching. The Department will also be expected to provide expertise in consultation relating to a Quality Assurance Program, clinical epidemiological research and research in medical economics.

Interested candidates should apply, with curriculum vitae and names of three references, to The Hospital for Sick Children, 555 University Avenue, Toronto, Ontario, Canada M5G 1X8, Attention Kerr M. Chalmers, Secretary to the Search Committee. (NW1743)A

ΕΘΝΙΚΟ ΙΔΡΥΜΑ ΕΡΕΥΝΩΝ

1958

THE NATIONAL HELLENIC RESEARCH FOUNDATION

ANNOUNCEMENT

The Institute of Biological Research of the National Hellenic Research Foundation seeks personnel for the following positions:

- One senior scientist to head a group of Genetic engineering — Molecular Biology of eukaryotes-Microbial genetics
- Two research associates to participate in the above group
- One research associate specialized in Cell Biology-Cytogenetics
- One research associate specialized in fluorescence and NMR spectroscopy in biological systems
- One research associate specialized in enzyme technology-Biotechnology

All candidates should hold a PhD and be greek citizens.

Full c.v. with publications and addresses of at least two persons for references should be addressed to. Mrs. D. Stefanou, Secretary, Institute of Biological Research, NHRF, Vassileos Constantinou 48, Athens, Greece, not later than June 15. (W1849)A

UNIVERSITY OF EDINBURGH

Regius Chair of Geology

The Secretary of State for Scotland invites applications for the Regius Chair of Geology in the University of Edinburgh which falls vacant on 1st October, 1985 following the retirement of Professor Sir Federick Stewart.

The successful candidate will be expected to have made an internationally recognised contribution within some field of the geological sciences and will assume the position of Head of Department. He/she must have outstanding leadership and administrative qualities and the ability to interact positively with academics and industry.

Further particulars of the appointment may be obtained from the Secretary, Room 3/114, New St Andrews House, Edinburgh EH1 3SY, with whom applications (13 copies, except in the case of overseas candidates who may submit only 2 copies), giving the names of three referees, and should be submitted not later than 9 August 1985.

6119)A

Recombinant DNA Specialist post-doctoral level

If your sights are aimed at the field of genetic engineering, focus in on a laboratory where sophisticated technology and the latest ideas go hand in hand with the strength of France's n° 1 chemical and pharmaceutical group-which also happens to be among the top 10 in the world The Rhône Poulenc Group provides Génétéca with an industrial scale structure for research, application and sales, thus giving Génétéca every chance to produce broad ranging applications and all of the resulting financial benefits. Ten years ago, the field of genetic engineering didn't even exist. Our main projects performed until 1984: Génétéca has successfully cloned and expressed the gene of a pharmaceutical enzyme, the numerous genes – approximately 20 – of the biosynthetic route to the vitamine B 12, an important drug and food additive, and the gene of two medically valuable human proteins

If you would like to broaden your professional horizons, join a laboratory that really counts in this field. You will find your working environment, just thirty minutes from the heart of Paris, both pleasant and stimulating.

Please send your application (résumé) to GENETICA,
160 quai de Polangis, 94340 Joinville-le-Pont, Paris - FRANCE

In the field of the infinitely tiny, Genetica has big plans.

media system

GENETICA
PARIS FRANCE

postdoctoral position polynucleotide structure

The Department of Exobiology of the University of Nijmegen conducts research in the field of chemical evolution. We are seeking a chemist with recent Ph.D. to participate in a project on primitive mechanisms of polynucleotide synthesis and replication.
Appointment will be in principle for one year, although there may be a possibility of extension.
Experience in the use of spectroscopic techniques for studying the structure and dynamics of polynucleotides is desirable, but other backgrounds will be considered.
Salary is dependent on experience (minimum Dfl. 3.502,– per month).
Candidates should submit a curriculum vitae referring to announcement nr. 85-25 and have two letters of reference sent within four weeks from the publication of this announcement to: Personnel Department of the Faculty of Science, Toernooiveld, 6525 ED Nijmegen, the Netherlands.

university of nijmegen

(W1840)A

Royal Postgraduate Medical School

(University of London)

DEPARTMENT OF HAEMATOLOGY

'NEW BLOOD' LECTURESHIP IN MOLECULAR GENETICS

Applications for the above post are invited from suitably qualified candidates with research experience in genetics and molecular biology. This Department has a strong research base with established groups in cell culture studies and in molecular genetics. The Department also hosts the MRC Leukaemia Research Unit. Our main research theme is the study of genetic and acquired blood disorders at the molecular level. The successful candidate will be expected to develop in due course his/her own autonomous research programme within this scope. The appointment will start 1 October 1985.

Salary in the range £7,520 to £14,925 plus £1,233 London Allowance a year.

Candidates, who should normally be under 35, may obtain further particulars from the Personnel Office or Professor L Luzzatto, Department of Haematology, Royal Postgraduate Medical School, Ducane Rd, London W12 0HS.

Applications, including curriculum vitae and the names of three referees, should be sent to the Senior Assistant Secretary at the Royal Postgraduate Medical School (ref: N7/8).

Closing Date: 7 June 1985 (6391)A

THE JOHNS HOPKINS UNIVERSITY

Applications are invited at the Postdoctoral Level for: (1) Pharmacologist to investigate the pharmacokinetics and biological properties of mismatched double-stranded RNA interferon inducers.

(2) Immunologist/Protein Chemist to carry out detailed studies on DNA-protein interactions using monoclonal antibodies as a model system; to quantitate DNA base modifications induced by irradiation and oxygen radicals using an immunological approach. Appointments are immediately available.

Applicants should submit a curriculum vitae, a statement of research interests, transcripts and three letters of recommendation to: Dr. Paul O. P. Ts'o, Division of Biophysics, The Johns Hopkins University, School of Hygiene and Public Health, 615 N. Wolfe Street, Baltimore, Maryland 21205. (NW1735)A

F O M

Association Euratom-FOM
FOM-Institute for Plasma Physics
"Rijnhuizen"
Nieuwegein, The Netherlands

This Institute is working in experimental and theoretical plasma physics. Part of the work is done in collaboration with other European laboratories, including JET.

Applicatons are invited for the post

HEAD OF THE EXPERIMENTAL DIVISION

whose task is to direct approximately forty experimental physicists and laboratory assistants and to share responsibility for the management of the Institute with the Director and the theoretical, technical and administrative division heads.

Candidates should have made significant contributions to thermonuclear plasma physics and should have proven abilities to direct an experimental group and to participate in international collaboration.

For infomation concerning this post, please contact Prof. C.M. Braams, director of the Institute tel. 03402-31224. Applicants, as well as persons who wish to propose qualified candidates, are invited to apply within two weeks after this advertisement appears, to the Secretary of the Selection Committee: Mr. H.J. Lammers, Postbus 1207, 3430 BR Nieuwegein, The Netherlands.

RESEARCH SCIENTISTS IN ORGANIC CHEMISTRY

The Dana-Farber Cancer Institute, affiliated with Harvard Medical School, announces openings for Ph.D. scientists of organic chemistry with a background in synthesis. Some experience in biochemistry would be desirable. Appointees will join a team involved in research and development of immunotoxins as reagents for treatment of human cancers. Appointments will be at either postdoctoral or more senior levels depending on experience.

Applicants should arrange for a curriculum vitae and 3 letters of recommendation to be sent to Dr. Walter A. Blättler, Division of Tumor Immunology, Dana-Farber Cancer Institute, 44 Binney Street, Boston, MA 02115.

An Affirmative Action/Equal Opportunity Employer. (NW1733)A

TUMOR IMMUNOBIOLOGIST

The Department of Pediatrics, Southern Illinois University School of Medicine invites applications for an Associate Professor alternate track faculty position. Ph.D. in immunology or related field required with four years postdoctoral experience including research related experience in tumor immunology. Minimum salary $39,000, salary is negotiable based on experience. Applicants may have research experience in one or more of the following areas: Surface antigens or tumor cells, polyamines, natural resistance, bone marrow transplantation.

Send curriculum vitae and description of research abilities to: L. G. Thatcher, M.D., Chairman, Department of Pediatrics, S.I.U. School of Medicine, P.O. Box 3926, Springfield, Illinois 62708. S.I.U. School of Medicine is an equal opportunity/affirmative action employer. Applications will be accepted until June 14,

HEAD, BASIC SCIENCE DEPARTMENT

The School of Dental Medicine, University of Connecticut Health Center, is seeking to fill the position of Head, Department of Oral Biology. The position is a full-time, tenure track appointment that will be filled at the rank of Professor. The applicant must hold a PhD degree in one of the biomedical sciences or a professional doctoral degree with equivalent research training, be actively engaged in basic research, and have teaching experience at the graduate level. Some administrative experience is preferred.

The Department of Oral Biology serves the basic science needs of the School of Dental Medicine. The Department is multidisciplinary, with its ten full-time faculty representing the areas of molecular biology, cell biology, developmental biology, and the neurosciences. The Department's principal educational responsibility is the administration of a large Ph.D. program; it also provides additional teaching contributions to the undergraduate dental and medical curricula, and dental residency programs. **Resumes should be sent to: Dr. John Patterson, Chairman, Oral Biology Search Committee, Department of Physiology, University of Connecticut Health Center, Farmington, Connecticut 06032. Affirmative Action/Equal Opportunity Employer.** (NW1732)A

POSTDOCTORAL POSITION

Studies of the biochemistry and genetics of antibiotic production by *Streptomyces*. Characterization of mutants; plasmid isolations; in vitro DNA manipulations; gene cloning; enzyme isolation. Background in rDNA work and protein purification required with Ph.D. in microbiology, genetics, or biochemistry. Available 1 October 1985, for a period of 1 or 2 years. **Send résumé and two letters of recommendation to: Professor C.R. Hutchinson, School of Pharmacy, University of Wisconsin, Madison, Wis. 53706; telephone: 608-262-7582.** (NW1744)A

Public Service Commission of Canada / Commission de la Fonction publique du Canada

Research Scientist, Earth Structure Studies

Energy, Mines and Resources
Earth Sciences
Ottawa, Ontario

We require a scientist to conduct field investigations and research studies into the nature and structure of near-surface rock bodies and major geological features of crustal and mantle scales. Emphasis will be on the application of electrical induction techniques, which may include audio-magnetotelluric surveys, real-time magnetotelluric surveys, standard magnetotelluric surveys and controlled source induction surveys. Other geological and geophysical methods may be incorporated as necessary. You will be expected to carry out field investigations in all parts of Canada, from the east and west coasts to the Arctic Ocean Basin. The research studies will demand extensive use and development of state-of-the-art computer-based processing and interpretational methods.

You require graduation with a doctoral degree from a recognized university, or a lesser degree with evidence of research experience and productivity equivalent to that of a doctoral degree in geophysics, geology, physics, mathematics or a related field. It is essential that you possess experience in the collection, processing and analysis of geophysical data, with emphasis on the magnetotelluric method. Knowledge of either English or French is essential.

We offer a salary ranging from $28,176 to $52,409 commensurate with your qualifications and experience.

Forward your résumé and/or application form, quoting reference number S-85-31-5193-47JG-(G26), to.
Joan Girling (613) 996-8054

HERIOT-WATT UNIVERSITY
Department of Physics
LECTURESHIP IN PHYSICS
(Reference No. 42/85)

Applicants should be either experimental or theoretical physicists or electronic engineers. Strong preference will be given to candidates with research interests in optoelectronics, laser physics, semiconductor physics, instrumentation. A Ph.D. and subsequent research experience is expected.

Information Technology Lectureship (Reference No. 43/85)

The department has a flourishing research group working on optical bistability based devices. Candidates with experience in optical signal/image processing are sought in order to expand our work in Optical parallel Processing and Optical Computer Architecture.

Appointees to the above posts will be expected to contribute variously to teaching on the degree courses of Physics/Applied Physics/Computational Physics and the M.Sc. course in Opto-electronic and laser Devices. Industrial collaborations are encouraged both in the teaching and research activities.

Salary scale £7,520 - £14,925 per annum (under review) plus USS benefits.

For further particulars and an application form please write to the Staff Officer, Heriot-Watt University, Chambers Street, 4081A

MOLECULAR AND CELLULAR IMMUNOLOGY
UNIVERSITY OF CALIFORNIA, BERKELEY

The Department of Microbiology and Immunology at the University of California, Berkeley is seeking highly qualified applicants to fill a faculty position at the Assistant Professor level beginning July 1, 1986. Applicants should hold a Ph.D. or M.D. degree and have a strong record of scholarly achievement and outstanding research contributions. Responsibilities include development of a graduate-level course in molecular aspects of cellular immunology, participation in undergraduate instruction in immunology, and maintenance of a strong independent research program to provide training for graduate students and postdoctoral fellows. Preference will be given to candidates whose major research interest involved molecular mechanisms of cellular immunobiology.

Please send curriculum vitae, summary of research interest, and the names of three references by July 15, 1985 to:
Dr. James P. Allison
Chairman, Search Committee
Department of Microbiology and Immunology
University of California
Berkeley, CA 94720.

The University of California is an Equal Opportunity Affirmative Action Employer. (NW1742)A

RESEARCH & DEVELOPMENT SCIENTISTS OXFORD

Genetics International an American Biotechnology company involved in the development of novel biomedical assays require highly motivated individuals interested in the areas of Immunology, Biochemisty, Enzymology, Electrochemistry and Synthetic Organic Chemisty.

These positions would suit persons holding either a first degree M.Sc. or a Ph.D. with or without prior industrial experience. Applicants should be ideally in their twenties and be able to demonstrate their personality and maturity and contribute to a multidisciplinary area.

The salary and benefits package for these positions is very attractive, and will include a pension scheme and if applicable generous relocation expenses will be provided. Opportunity exists for the individuals to participate in the company Executive Stock Option Scheme.

To help us assess your suitability for these posts please send in a letter of application together with a C.V. and names of 3 referees.

Please Apply to:
Mrs Frankie Minal,
G.I. (UK) Inc.,
11 Nuffield Way,
Ashville Trading Estate,
Abingdon, Oxon. OX14 1RL.

ST GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)

DEPARTMENT OF PHYSIOLOGY

SERC POSTDOCTORAL RESEARCH FELLOW

required for 3 years for work on the electrophysiology and pharmacology of amino-acid function in lamprey spinal cord. A background in electrophysiology would be an advantage. Initial salary up to £8753 pa.

Application form and further details from the Personnel Officer, St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE Closing date 31st May.

(6392)A

LEUKAEMIA RESEARCH FUND CENTRE AT THE INTSTITUTE OF CANCER RESEARCH

TECHNICIAN/RESEARCH OFFICER

required to help organise a molecular biology laboratory and actively participate in its research programme into Cellular and Molecular Biology of Human Leukaemia. Experience in recombination DNA techniques essential. Candidates should have a degree, HNC or equivalent qualification.

Salary will be in the range of £5,738 — £6,942 + £1,042 pa London Weighting allowance, depending on qualifications and experience. Applicants are advised that in the majority of the Institute's premises smoking is prohibited.

Applications in duplicate with the names and addresses of two referees should be sent to the Personnel Officer, Institute of Cancer Research, 17A Onslow Gardens, London SW7 3AL, quoting reference 301/B/86. (6371)A

THE UNIVERSITY OF AUCKLAND
New Zealand

LECTURESHIP/SENIOR LECTURESHIP IN MARINE BIOLOGY

MARINE BIOLOGY
(Leigh Laboratory)

Applicants should have a higher degree and teaching and research experience in either botanical or zoological aspects of Marine Science. The laboratory's current activities cover intertidal and subtidal experimental ecology of both plants and animals, phytoplankton and zooplankton studies and fish physiology and behaviour. The successful applicant will be expected to support and encourage these or related research programmes, assist in the teaching of marine biology and to contribute generally to the management of the Laboratory. Salaries will be established within the appropriate scale for Lecturers NZ$23,622-$27,929 and Senior Lecturers NZ$29,430-$37,240. Conditions of Appointment and Method of Application are available from the Assistant Registrar (Academic Appointments), University of Auckland, Private Bag, Auckland, New Zealand, or the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications in accordance with the Method of Application should be forwarded as soon as possible, but not later than 31 May 1985. (W1845)A

BIRBECK COLLEGE
University of London

DEPARTMENT OF CRYSTALLOGRAPHY

LECTURESHIP IN MOLECULAR BIOLOGY: PROTEIN ENGINEERING

Applications are invited for a lectureship to be held in the Department of Crystallography established under the UGC's "New Blood" scheme and tenable from 1st October 1985.

Applicants should have a first degree in a relevant biochemical subject and practical experience in recombinant DNA techniques including site-specific mutagenesis in the study of protein structure and function. The successful candidate would be expected to work in collaboration with the structural molecular biology group of Professor T L Blundell, FRS and his colleagues.

Candidates should normally be less than 35 years of age but exceptionally well-qualified canidates just over this limit may be considered. Appointment will be at an appropriate point on the Lecturers' scale £8,753-£16,158 pa inclusive of London Allowance (under review). Further particulars may be obtained from the Assistant Secretary (Personnel), (CE), (N), Birkbeck College, Malet Street, London WC1E 7HX (Tel: 01-580 6622, ext 529), to whom applications in duplicate including full cv and names of two referees should be sent by 7th June 1985.

PRESIDENT
THE AMERICAN MUSEUM OF NATURAL HISTORY

The trustees of The American Museum of Natural History invite applications for the position of President and Chief Executive Officer of the Museum. The President is responsible for the effective governance of this prestigious museum and related entities.

Reporting to the President are the Director, the Deputy Director for Research (9 curatorial departments), Deputy Director for Administration, Assistant Director for Financial Affairs, Department of Development and Public Affairs, Department of Library Services, Department of Exhibition and Graphics, Department of Education, *Natural History* Membership, and the Planetarium.

The annual operating budget of the Museum is $35 million, there are 800 employees, 23 buildings, a $95 million endowment, and 2.5 million visitors a year.

Candidate should have the following qualifications:

* Demonstrated imaginative leadership and an ability to work with diverse constituencies
* A strong interest in the natural sciences and appreciation of scholarly work A Ph.D. in the Natural Sciences would be highly desirable.
* Proven administrative and financial skills in the administration of large organizations.
* Experience in major fund raising.

Letters of nomination or application, coupled with resume/vitae and information on current compensation should be submitted in confidence no later than July 1, 1985 to: Box 1737, c/o Nature Classified, 65 Bleecker St, New York, NY.10012.

Resumes will neither be acknowledged nor returned.

The American Museum of Natural History is an equal opportunity employer. (NW1737)A

MELBOURNE TUMOUR BIOLOGY BRANCH
LUDWIG INSTITUTE FOR CANCER RESEARCH

CELL/MOLECULAR BIOLOGIST, REF.3/85

The Melbourne branch of the Ludwig Institute is undertaking a research programme directed towards the understanding of the cellular and molecular basis of growth regulation in normal and neoplastic tissues.

A Post-doctoral Scientist is required to work in an active programme on the retroviral transformation of murine epithelial and T-lymphocyte cells in vivo and in vitro. Experience in tissue culture and in either basic protein chemical or molecular biological techniques are required.

Initially the position will be for a period of 2 years with the possibility for extension. The salary will be equivalent to research fellow (grade 1 levels 1-4, dollars Aust 21,411 to dollars Aust. 23,284 per annum) depending on experience. The Ludwig Institute will pay the transfer expenses to Melbourne including an Apex Company airfair for the successful candidate and his/her dependents.

Applications should include above reference number, curriculum vitae and the names and addresses of 2 referees. Address to: — The Director, Ludwig Institute for Cancer Research, P.O. Royal Melbourne Hospital, Victoria 3050, Australia. (W1836)A

UNIVERSITY OF LINZ/AUSTRIA
Institute of Biophysics offers

3 POSTDOCTORAL POSITIONS

The Institute provides, under guidance of Prof. H. Schindler, most advanced techniques of membrane reconstitution, aimed at relationships between membrane structure and functions, especially of ion transport through membrane channels. The new collaborators are invited to join current studies of ion channels involved in heart function and other electrical and chemical excitation processes. Applicants should be competent in either of the three fields:

Membrane Physiology (strong background either in electophysiology including patch clamp techniques, or in physiology of cardiovascular membranes including experience in cell-culturing),

Membrane Biochemistry (Broad expert knowledge in isolation of membranes and of membrane proteins to purity),

Membrane Biophysics (physicist or physico-chemist with either practical experience with membranes or involved in theoretical approaches to membranes)

For all three posts, training in membrane reconstitution is not required and will be provided. Each appointment will be, in the first instance for one year with the possibility for prolongations and a chance of promotion to a senior position

Applications, including curriculum vitae, names and addresses of two referees, and a detailed account of previous relevant experiences should be sent before 15th May 1985 to Prof. H. Schindler, University of Linz, Institute of Biophysics, A-4040 Linz, Austria. Tel: 01043/ 732/23 13 81 Ext. 530, 531. (W1841)A

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF MEDICINE

TECHNICIAN GRADE 3

to assist with a project concerning Radioimmunoassay of peptide and steroid hormones, measurement of catecholamines by HPLC. Assistance with hypothalamic perfusions and related work.

Candidates must possess ONC or appropriate equivalent and three years appropriate experience.

Salary within a range £5,399 — £6,325 per annum.

This post is available for one year.

Application forms may be obtained from the Registrar, the University, PO Box 147, Liverpool, L69 3BX.

Quote Ref: RV/259/N (6355)A

UNIVERSITY OF LEICESTER

DEPARTMENT OF MICROBIOLOGY

RESEARCH TECHNICIAN GRADE 3

Applications are invited for the post of Technician Grade 3 tenable for a maximum of three years. Initial salary will be in the range of £5,399 — £5,701 per annum.

The position is funded by the Wellcome Trust and the successful applicant will be involved with the identification and biotyping of medically important yeasts. Some experience of microbiology is essential: experience in medical mycology would be an advantage.

Send applications, including a curriculum vitae and the names and addresses of two referees, to Dr F C Odds, Department of Microbiology, University of Leicester, Leicester LE1 7RH. (6339)A

PUBLIC HEALTH LABORATORY SERVICE BOARD

PHLS Centre for Applied Microbiology & Research

Therapeutic Products Laboratory

BIOCHEMIST/ MICROBIOLOGIST

A graduate is required for research into the isolation and evaluation of methionine degrading enzymes for cancer therapy. The post is for a maximum period of 3 years and is financed by the Cancer Research Campaign. The work will be under the direction of Dr M Tully (telephone Idmiston (0980) 610391 ext 424) from whom further information may be obtained.

The successful applicant will be graded Basic Grade Microbiologist.

Salary £6,559 — £7,063

National Health Service terms and conditions will apply.

Application forms are obtainable from the Personnel Officer, PHLS Centre for Applied Microbiology & Research, Porton Down, Salisbury, Wilts SP4 0JG. Telephone Idmiston (0980) 610391.

Closing date 31 May 1985.

Please quote Reference No 41 when applying. (6348)A

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF GENETICS

NEW BLOOD APPOINTMENT

Applications are invited for a U versity Lectureship or Demonstrat ship (equivalent to UAL) in the fi of molecular plant genetics under new blood scheme. The pers appointed will be expected establish a research programme a to undertake teaching.

Relevant pensionable scales stipends are as follows:

UL £10,330 a year rising by annual increments to £15,930 U £7,980 rising by 4 annual increme to £9,860.

Informal enquiries concerning t post can be made to Professor J I Finchman, Department of Geneti Downing Street, Cambridge C 3EH.

Further particulars may obtained from Secretary to t Appointments Committee, Facu of Biology A, Zoology Departme Downing Street, Cambridge CB2 3 to whom applications (3 copi including Curriculum Vitae a names of three referees should be s to reach him by 31st May 19 Applications for this post should marked 'NBGEN'. UNIVERSITY OF EDINBURGH

DEPARTMENT OF ZOOLOGY

POST DOCTORAL RESEARCH FELLOW IN DEVELOPMENTAL NEUROBIOLOGY

Applications are invited for an MRC funded post to investigate axonal and cellular interactions in vitro, using amphibian nervous tissue. Candidates should have experience in neural tissue culture and a background in cell biology or biochemistry would be helpful. The person appointed will join a small team investigating the specificity of nerve connections in development and regeneration. A well equipped laboratory and technical assistance are available.

The post is tenable for three years starting in September or October this year. The salary range (Grade 12) is £7,520 - £12,150 per annum.

Applications (three copies, including CV and the names of two referees) to Dr R M Gaze, Department of Zoology, West Mains Road, Edinburgh, EH9 3BT, by 30th May 1985.

Please quote reference No 5250. (6364)A

THE UNITED MEDICAL AND DENTAL SCHOOLS

St Thomas's Campus

RESEARCH TECHNICIAN

required from July '85 for neurophysiological laboratory. Duties involve general practical work and also fabrication/testing of laboratory equipment. Previous laboratory experience required; interest/training in histological procedures, electronics or photography useful.

Salary on Whitley Council MLSO Scale, 3 year post on MRC Grant.

Apply with cv and names and addresses of 2 referees to Staffing Officer, Dean's Office, St Thomas's Hospital Medical School, London SE1 7EH, before 23rd May, 1985. For informal enquiries, please contact Dr S McMahon, tel 01 928 9292 Ext 2241. (6373)A

UNIVERSITY OF EDINBURGH

TEMPORARY LECTURER IN ZOOLOGY

Applications are invited for a temporary Lectureship in Zoology for one year only from 1 October 1985. This post is financed by the Nuffield Foundation and the maximum salary is point 4 of the Lecturer scale. The main teaching duties are in evolution and population biology. Further particulars can be obtained from the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh EH8 9YL with whom applications by letter (2 copies) including a curriculum vitae and the names of two referees should be lodged not later than 31 May 1985. Please quote reference number 1188. (6296)A

UNIVERSITY OF YORK

DEPARTMENT OF ELECTRONICS

POSTDOCTORAL RESEARCH ASSISTANT/RESEARCH ASSISTANT

Applications are invited for a 3 year post associated with the development of a dispersive EXAFS facility for the SERC Synchrontron Radiation Source at the Daresbury Laboratory. EXAFS is an exciting x-ray investigatory technique, using a dispersive geometry which enables atomic structure to be measured on the millisecond timescale.

The person appointed will be concerned with the design and development of this facility, which will exploit solid-state devices as x-ray imagers under the control of microprocessors. The project is interdisciplinary covering aspects of applied physics, advanced electronic and mechanical system implementation and software techniques.

Work will take place at York and at Daresbury Laboratory, Cheshire.

Salary on a scale up to £8,920 per annum, with USS.

Three copies of applications, with full curriculum vitae and naming two referees, should be sent by 31 May 1985 to Registrar's Department (Appointments), University of York, Heslington, York YO1 5DD. Further particulars are available. Please quote reference number N/6200.(6398)A

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF ANATOMY & EMBRYOLOGY

RESEARCH ASSISTANT

required for project on the control of nerve and muscle differentiation using a variety of techniques. Experience of tissue culture an advantage.

The post is funded by the MRC until 31 August 1987. Salary will be at a point on the RA range IB scale £6,600 - £8,400 according to age, qualifications and experience.

Applications (cv and 2 referees) to: Dr A Warner, Dept of Anatomy, University College London, Gower Street, London WC1E 6BT. Closing date: 25 May 1985. (6350)A

UNIVERSITY OF LONDON

READERSHIP IN PLANT BIOCHEMISTRY TENABLE AT ROYAL HOLLOWAY AND BEDFORD COLLEGES

The Senate invite applications for the above Readership from 1 October 1985. Preference will be given to candidates who have considerable experience in the molecular biology of plant development and an interest in postgraduate courses. Applications (11 copies) should be submitted to the Academic Registrar (N), University of London, Malet Street, London WC1E 7HU, from whom further details should first be obtained.

Closing date for receipt of applications: 14 June 1985. (6351)A

UNIVERSITY OF ZIMBABWE

LECTURESHIPS/SENIOR LECTURESHIPS
ASSOCIATE PROFESSORSHIPS

DEPARTMENT OF BIOLOGICAL SCIENCES (3 posts)

Post A Freshwater Biology: A Lecturer specialising in some aspect of Freshwater Biology is required to teach general undergraduate courses in ecology and to contribute to an MSc programme in Hydrobiology. Any area of Freshwater Biology (except Fisheries Biology) will be considered but candidates specialising in phytoplankton/primary production studies will be of particular interest. Experience of tropical lakes or running waters is desirable. Applicants must have a first degree and a PhD and/or research experience in the appropriate area of specialisation Appointment will be for two years in the first instance.

Post B Plant Physiology: A Lecturer is required to contribute to undergraduate and postgraduate courses in Plant Physiology Specialists in any plant physiological discipline will be considered but the Department will view with particular favour applicants specialising in photosynthesis, water relations or seed physiology. Applicants must have a first degree and a PhD and/or research experience in some aspect of plant science.

Post C Nematology/Soil Zoology: Applicants should be experienced in the general area of Nematology and/or Soil Zoology. Any area of specialisation within these disciplines will be considered but preference will be given to candidates with research experience with plant-infecting nematodes. The successful candidate should have a first degree in some aspect of biological or agricultural science and a PhD and/or research experience in the appropriate area of specialisation. He/She will be required to contribute to undergraduate courses in invertebrate zoology, parasitology and soil and ecology, and to appropriate postgraduate courses.

SALARY SCALES
Lecturer Z$11,880 - $20,076; Senior Lecturer Z$20,580 - $23,400; Associate Professor Z$21,084 - $23,904 (including allowance). Appointment on the above scales according to qualifications and experience.

CONDITIONS OF SERVICE: Both permanent and short-term contracts are offered. Persons who are not Zimbabwean citizens may be appointed only on short-term contract basis with an initial period of two years. Short-term contracts may, in exceptional cases, be extended.

Six copies of applications giving full personal particulars which should include full name, place and date of birth, qualifications, employment and experience, present salary, date of availability, telephone number and names and addresses of three referees should be addressed to the Director, Appointments and Personnel, University of Zimbabwe, P.O. Box MP 167, Mount Pleasant, Harare, Zimbabwe (Telex: 4-152 ZW). Applicants in the UK should also send an additional copy to the Secretary General, Association of Commonwealth Universities, (Appts), 36 Gordon Square, London WC1H 0PF. Closing date for receipt of applications is **14 June 1985.** (W1848)A

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF GENETICS

LECTURESHIP

(Molecular Genetics)

Applications are invited for a Lectureship in Genetics available from 1st October 1985. We are seeking to appoint a research scientist active in the field of molecular genetics who wishes to undertake a research programme involving the use of recombinant DNA techniques. Facilities are well established in the department of prokaryote gene cloning, the molecular genetics of fungi, DNA sequencing, the cloning of higher plant DNA and animal virus research.

Salary will be on the Lecturers' scale: £7,520 — £14,925 per annum, according to age, qualifications and experience.

Further particulars may be obtained from the Senior Assistant Registrar (F P), The University, 6 Kensington Terrace, Newcastle upon Tyne, NE1 7RU, with whom applications (3 copies) together with the names and addresses of three referees should be lodged not later than 27th May 1985. (6369)A

Southampton THE UNIVERSITY

Department of Chemistry

POSTDOCTORAL RESEARCH FELLOW IN INTERFACIAL STUDIES

Applications are invited for the above post funded by the Department of Energy, for work in the measurement of very low values of interfacial tension, under the Enhanced Oil Recovery programme. The work will involve the use of computerised video digital techniques applied to interfacial studies and the extension of these measurements to pressures up to 100 bar.

The post is currently available and the appointment will be initially for a one year period on a salary range up to £9390 per annum.

Applications naming two references should be sent to Dr D J Schiffrin, Chemistry Department, the University, Southampton, S09 5NH from whom further information can be obtained. (6381)A

UNIVERSITY OF LONDON
THE INSTITUTE OF DERMATOLOGY
Department of Electron Microscopy and Cell Pathology

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the above position which will be available for 2 years in the first instance. The chief aim of the research will be to develop in-vitro techniques for studies on cell-substrate interations as part of a long term investigation on genetic and acquired blistering disorders. Experience in cell culture methods and immunohistochemistry is desirable.

Salary according to age and experience on 1A scale. Further details from Dr. R.A.J. Eady, Institute of Dermatology, Homerton Grove, London E9 6BX. (Tel: 01-985 7061, Ext: 66).
(6404)A

UNIVERSITY OF LEICESTER
DEPARTMENT OF GENETICS

Applications are invited for the post of
RESEARCH ASSISTANT (1B)
for three years from 1st September 1985 to work on cell differentiation in the slime mould Physarum polycephalum. Starting salary £6600, rising to £7520 pa. The project, funded by SERC, is a collaboration with Sheffield University which will employ time-lapse filming to analyse cellular events of development from amoeba to plasmodium in mutant strains. No previous experience is necessary but applicants should have, or expect shortly to obtain, a degree in one of the Biological Sciences. Knowledge of aseptic techniques and/or photomicrography would be an advantage.

Applications with curriculum vitae and names of two referees should be submitted to Dr Jennifer Dee, Department of Genetics, University of Leicester, University Road, Leicester LE1 7RH, by 17th May 1985 Further details may be obtained from Dr Dee: telephone (0533) 551234 ext 393.
(6384)A

Southampton THE UNIVERSITY

INSTITUTE OF CRYOGENICS

Applications are invited for the post of Lecturer in the Institute of Cryogenics. Candidates should have a Ph.D. and research experience in applied low temperature physics or cryogenic engineering and a strong interest in teaching. The post will require development of links with industry via collaborative research and continuing education activities.

Salary within scale — £7,520 — £14,925 per annum (under review). The appointment will be for an initial five year period.

Further particulars may be obtained from Mr. D.A.S. Copland, The University, Southampton, SO9 5NH, to whom applications (7 copies from U.K. applicants) should be sent not later than 27 May 1985 quoting reference number2155. (6359)A

DURHAM UNIVERSITY
DEPARTMENT OF MATHEMATICAL SCIENCES

Applications are invited for the post of
POSTDOCTORAL SENIOR RESEARCH ASSISTANT
in Elementary Particle Theory tenable for fourteen months from 1 August 1985 or later by arrangement under the direction of Drs E F Corrigam and D B Fairlie for investigations in the Stucture of Gauge Theories. There is scope for working on a variety of different topics.

Initial salary in the range £7,520 — £9,860 per annum plus superannuation.

Application (3 copies) naming 3 referees should be sent by 31 May 1985 to the Registrar, Science Laboratories, South Road, Durham DH1 3LE from whom further particulars may be obtained. (6368)A

UNIVERSITY OF CAMBRIDGE
CAVENDISH LABORATORY

RESEARCH ASSOCIATE IN HIGH ENERGY PHYSICS

Applications are invited for the above SERC-funded post. Candidates should have or be shortly completing a PhD in Particle Physics or have related experience. The laboratory has an active research programme at the antiproton-proton Collider at CERN, and is involved with the construction of the OPAL detector for the study of electron-positron collisions at LEP. It is envisaged that the successful candidate would join the Collider research programme.

The appointment commences on 1 July 1985. Salary will be in the range £7,520 to £9,860 pa depending on age and experience. The appointment will be initially for two years but is renewable.

Letters of application including curriculum vitae and the names of two referees should be sent to Mr J Deakin, Cavendish Laboratory, Madingley Road, Cambridge CB3 0HE.

Further particulars can be obtained by contacting Dr J G Rushbrooke at this address. Closing date for applications is 20 May 1985.
(6363)A

UNIVERSITY OF NOTTINGHAM
DEPARTMENT OF ZOOLOGY

POSTDOCTORAL RESEARCH ASSISTANT

A one-year post is available from 1st October 1985 to work on a SERC funded project looking into risk-sensitive and time-constrained foraging in shrews. Applicants should have a working knowledge of optimal foraging theory and experience with laboratory behavioural studies. The appointment will be within the first two points of the postdoctoral scale.

Applications with curriculum vitae to Dr C J Barnard, Department of Zoology, University of Nottingham, University Park, Nottingham, NG7 2RD. (6397)A

MAX-PLANCK-INSTITUTE FOR IMMUNOBIOLOGY
Freiburg, FRG

searches for a
POSTDOCTORAL RESEARCH FELLOW OR AN ASSISTANT RESEARCH SCIENTIST

Applications are invited for work in the fields of T-cell differentiation and cancer-related immunobiology, mainly employing molecular biological techniques. Therefore experience in molecular genetics is of advantage. The position is immediately available.

Applicants should forward their CV and letters of recommendation as soon as possible to: Dr J T Epplen, Max-Planck-Institut fur Immunbiologie, Stubeweg 51, D-7800 Freiburg i Br, FRG. (W1839)A

INSTITUTE OF CANCER RESEARCH

ELECTRON MICROSCOPE TECHNICIAN

required for the Institute of Cancer Research, Fulham Road. The work involves mostly transmission E M of fixed material with some negative staining and scanning work. The unit carries out E M studies for many departments within the Institute giving rise to a considerable variety of experimental material. Qualifications required are HNC or Degree in Biological Sciences. Previous E M experience considered essential. The post would particularly suit applicants with technical qualifications.

Salary will be in the range of £5,738 to £5,925 + £1,042 London Allowance, depending on qualifications and experience.

Applicants are advised that in the majority of the Institute's premises smoking is prohibited.

Applications in duplicate with the names and addresses of two referees should be sent to the Personnel Officer, Institute of Cancer Research, 17A Onslow Gardens, London SW7 3AL, quoting reference 301/B/84. (6366)A

THE QUEEN'S UNIVERSITY OF BELFAST
DEPARTMENT OF PHYSIOLOGY

RESEARCH ASSISTANT

The research assistant will work with Dr N G McHale on a project investigating the mechanism of lymph flow in sheep. The research is funded by the Wellcome Trust and the appointment will be for two years. Applicants should preferably have, or expect to obtain, a good honours degree in Physiology or a related discipline.

Commencing salary: £6,600 per annum.

Further particulars may be obtained from the Personnel Officer, The Queen's University of Belfast, BT7 1NN, Northern Ireland. Closing date: 31 May 1985. (Please quote Ref 85/W) (6401)A

UNIVERSITY OF OXFORD
NUFFIELD DEPARTMENT OF PATHOLOGY

RESEARCH ASSISTANT

Applications are invited for the above position to work on the origin and function of osteoclasts in normality and bone disease. Applicants should have a degree in cell biology or molecular biology. The salary is funded by the Arthritis and Rheumatism Council for three years, on a maximum starting point of £6,600.

Applications, together with curriculum vitae and the names of two referees, should be sent to: Professor J O'D McGee, Nuffield Department of Pathology, John Radcliffe Hospital, Headington, Oxford, OX3 9DU, by 30th May, 1985, from whom further details can be obtained.
(6382)A

UNIVERSITY OF LIVERPOOL
CYTOGENETICS UNIT

SCIENTIFIC OFFICER (CYTOGENETICS)

Applications are invited from Science graduates for a basic grade post on the Whitley A scales. This Unit provides the Cytogenetics service for the Mersey Regional Health Authority. The post primarily involves work in prenatal diagnosis and experience in human cytogenetic techniques/tissue culture is desirable.

Salary, depending upon qualifications and experience, within the range £6,559 - £7,807 per annum (under review).

Application forms may be obtained from the Registrar, the University, PO Box 147, Liverpool L69 3BX. Forms should be received not later than 31 May, 1985.

UNIVERSITY OF OXFORD

New blood lectureship in Synaptic Pharmacology

In association with Lincoln College

Applications are invited for the above university lectureship tenable from 1 October 1985. Applicants should be under 35 years of age on 1 October 1985. Stipend according to age on the scale £7,520 to £15,930 (under review). The successful candidate may be offered a stipendiary Tutorial Fellowship at Lincoln College.

University Lectureship in Pharmacology

In association with Somerville or Hertford College

Applications are invited for the above post tenable from 1 October 1985. Stipend according to age on the scale £7,520 to £15,930 (under review). The successful candidate may be offered to stipendiary Tutorial Fellowship at Somerville College, the statutes of which provide that all Fellows shall be women, or, if a man is appointed, at Hertford College.

Further details may be obtained from Professor A.D. Smith, Department of Pharmacology, South Parks Road, Oxford OX1 3QT, to whom applications (nine typed copies, or one from overseas applicants) with the names of three referees should be sent by 30 May 1985. (6388)A

MOLECULAR BIOLOGIST

The Danish Cancer Society is opening a position as research professor to build up a molecular biology research unit at the Fibiger Institute, Ndr. Frihavnsgade 70, Copenhagen, Denmark.

The institute is a multidisciplinary research institute involved in several areas of cancer research including tumor endocrinology, environmental carcinogenesis and tumor virology. The director of the Fibiger Institute is dr. Jørgen Kieler. It has a total staff of 50 employed including 5 senior investigators. It is sponsored by a core grant from the cancer society and project grants from the scientific grant committee of the Cancer Society. An international scientific committee acts as an advisory body for the institute.

The successful candidate will be responsible for establishing a research programme in molecular oncogenesis and should advise the other research units on aspects of molecular biology and its application.

The successful candidate should have extensive knowledge of recombinant DNA techniques and their application to cancer research problems. The candidate should be internationally recognised in the area of cancer research, and should have a proven record of scientific accomplishments.

The appointment is for a 5-year period. A tenure position may become vacant during the initial period.

Research facilities, research funds and staff requirements are negotiable with the Executive Committee of the Cancer Society. Salary is negotiable depending on scientific qualifications and accomplishments of the candidate

The application should be received by the chairman of the Danish Cancer Society: Professor, dr. med. Steen Olsen, Sølundvej 1, DK-2100 Copenhagen Ø., Denmark, *before 1 July, 1985.*

Application should include:
- **Curriculum vitae and bibliography**
- **Names of 3-4 referees**
- **A short summary of past and current research activities and a proposal for future research.**

The applications will be evaluated by a committee appointed by the Scientific Grant Committee of the society after consultation with the International Scientific Advisory Committee.

Additional information is available from the director or from the chairman of the Danish Cancer Society. (W1821)A

SACCHARIDE CHEMISTRY

Monsanto Company's Health Care Division has an opending for a carbohydrate chemist experienced in the chemical synthesis of monosaccharides and polysacharides. Applicants should be sufficiently experienced in this specialty to design and carry out the synthesis, purification and characterization of known and novel monosaccharides and polysaccharides with a high degree of proficiency. The position may entail directing a group of chemists in the preparation of polysaccharides of biological interest.

Please forward your resume in confidence to: **Dr. P.R. Schenkenberg, Box N-1; MONSANTO COMPANY; Mail Zone G4NG; 800 N. Lindbergh Blvd., St Louis, MO 63167.** An Equal Opportunity Employer M/F/H/V.

GRANTS and SCHOLARSHIPS

UNIVERSITY OF WALES COLLEGE OF MEDICINE
DEPARTMENT OF CHILD HEALTH
Applications are invited for a
POST-GRADUATE SCHOLARSHIP

to investigate androgen action and metabolism in disorders of sexual differentiation in humans, using tissue culture and cell fractionation techniques.

Applicants should have, or expect to gain, a first or upper second class honours degree in Biochemistry or a related science discipline.

The scholarship will commence in September 1985 and is tenable for a 2 year period (subject to a probationary year), with possible extension for a further year thereafter. The results are expected to be submitted for a PhD degree.

Further particulars and application forms (quoting Ref No C10/61) may be obtained from the Registrar and Secretary, University of Wales College of Medicine, Heath Park, Cardiff CF4 4XN (Tel No 0222-755944 Ext 2296) as soon as possible Closing date for application: 31st May, 1985. (6402)H

ASSISTANTSHIPS

FACULTY OF SCIENCE

RESEARCH ASSISTANTSHIPS
Marine Biology/ Chemistry/ Human Geography

Salary £5910 - £6657

(pay award pending)

Posts are available for the following projects -

1 Ecology of the velvet swimming crab, Liocarcinus puber (Brachyura, Portunidae)

2 Polycyclic Aromatic Hydrocarbons in engine sump oil. Mutagenicity, bioavailability and environmental fate.

3 The regional impact of the European Community's Common Fisheries Policy.

Applications are invited from graduates with good honours degrees in subjects appropriate to the proposed area of study and from undergraduates expecting to fulfil these requirements this summer For project 1, preference will be given to candidates with diving experience.

Research Assistants are expected to register for a higher degree (CNAA). Appointments are for periods of 2 years with possibility of a third year (fixed term contract)

Application forms — to be returned by Friday 31 May 1985 — and further details from Personnel Office, Plymouth Polytechnic, Drake Circus, Plymouth PL4 8AA (Tel: (0752) 264639).

SEMINARS and SYMPOSIA

INTERNATIONAL SYMPOSIUM
ROLE OF DNA IN BRAIN ACTIVITY
Ravello, Italy — May 27-29, 1985

TOPICS: Chromatin structure in neurons. Neuronal hyperploidy. Brain DNA turnover in learning and sleep Enzymology of DNA replication and repair. Brain-specific transcripts. Axoplasmic mRNA Cloning and expression of nucleic acid sequences coding for brain peptides, hormones, receptors and transmitter enzymes. Transcription and manipulation of human genes in neurological diseases

SPEAKERS: Barnard (London), Bernocchi (Pavia), Brown (Toronto), Davies (Oxford); De Gennaro (Martinsried), Ginzburg (Rehovot); Giraudat (Paris); Giuditta (Naples), Giuffrida (Catania); Hahn (Denver); Herbert (Eugene); Hyden (Goteborg), Kaplan (Pittsburgh); Kuenzle (Zurich); Lim (London); Mallet (Paris); P Mandel (Strasbourg); J.L. Mandel (Strasbourg), Mares (Prague); Milner (La Jolla), Morrison (Dallas); Reinis (Toronto); Richter (Hamburg); Roberts (New York), Scheller (Stanford); Soreq (Rehovot), Subba Rao (Hyderabad); Sutcliffe (La Jolla)

Late registrations will be accepted up to a maximum number of 120 participants. Registration fee 150 US Dollars Younger investigators 50 Dollars. No fee required for students Ravello is located at about one hour's drive from Naples

Further information from Prof. A. Giuditta, I.I.G.B., Via Marconi 10, Naples, Italy Tel 081-7257243. (W1842)M

CONFERENCES and COURSES

UNIVERSITY OF LEICESTER
SCHOOL OF BIOLOGICAL SCIENCES
DEPARTMENT OF BOTANY
BIOTECHNOLOGY SHORT COURSE CO-ORDINATOR

Applications are invited for the post of Biotechnology Short Course Co-ordinator from those with current research interests in the field of plant biotechnology. This post has lecturer status The person appointed will assess the demand for post-experience courses in biotechnology and subsequently in other areas of biotechnology. He or she will be expected to pursue a research programme within the Department of Botany.

This appointment will be for five years, supported by a grant from the DES under its PICKUP programme.

Initial salary will depend on qualifications and experience on the scale £7,520 to £14,925 (under review).

Further particulars and application forms can be obtained from the Registrar, University of Leicester University Road, Leicester, LE1 7RH, to whom applications should be returned by 31 May 1985. (6280)C

advertise your qualities and qualifications through the most influential science weekly in the world at a special reduced cost of 25p a word. (Personal Box Numbers £2). Advertisements must be pre-paid and sent to: Nature Classified (Appts Wtd), 4 Little Essex Street, London WC2R 3LF. (890)B

STUDENTSHIPS

MEDICAL RESEARCH COUNCIL

Institute of Hearing Research
Nottingham

RESEARCH STUDENTSHIP

Applications are invited for a 3-year MRC studentship from graduates holding, or expecting to obtain, an upper second or first class honours degree in any biological subject. The successful candidate will study structural and functional development of the auditory system, with emphasis on abnormal development processes leading to deafness.

Applications should include a cv and names and addresses of two referees. Further details may be obtained from Dr K P Steel, MRC Institute of Hearing Research, University of Nottingam, Nottingham NG7 2RD. Tel: 0602-223431. (6406)F

UNIVERSITY OF LIVERPOOL

Institute of Medical and Dental Bioengineering

RESEARCH STUDENTSHIPS

A small number of studentships is available in this interdisciplinary institute for research leading to a higher degree. The precise project will depend on the academic background and interests of the student but will be in one of the following areas:

Blood flow in arterial prostheses. Interactions between metals and tissues Polymer degradation. Tissue reactions to implanted particles.

Candidates should expect to obtain a good honours degree in an appropriate biological or physical science (eg materials science, engineering, chemistry, biochemistry, cell biology).

Applications, together with the names of two referees, should be received as soon as possible by The Registrar, The University, PO Box 147, Liverpool, L69 3BX.

Quote Ref: RV/263/N (6353)F

THE ROWETT RESEARCH INSTITUTE

Bucksburn, Aberdeen, AB2 9SB

RESEARCH STUDENTSHIP IN ANIMAL NUTRITION

Applications are invited for a Studentship leading to a PhD (Aberdeen University) for research into the factors which influence rumen development and hence intake of dry feed in young calves. The Project, sponsored by British Sugar PLC, will investigate how the physiological/biochemical mechanisms of the developing rumen respond to changes in the nature of the carbohydrate source supplied in weaner rations.

Applicants should possess or expect to obtain this year a good honours degree in agricultural biochemistry, nutrition or any related subjects.

Applications, including CV and the names of two referees should be addressed to the Secretary, Rowett Institute, Bucksburn, Aberdeen.

Closing date 30 May 1985. (6336)F

THAMES POLYTECHNIC

SCHOOL OF BIOLOGICAL SCIENCES AND ENVIRONMENTAL HEALTH

SERC RESEARCH WORKER IN PLANT MOLECULAR BIOLOGY

Applications are invited from recent honours graduates or postgraduates to work with Dr R Yon on 'Protein structure and gene organisation of pyrimidine-pathway enzymes in higher plants'. Practical experience in protein and/or nucleic acid biochemistry would be of value. The post is tenable for three years and registration for a higher degree will be considered.

Salary: £6,219 per annum inclusive.

SERC CASE STUDENTSHIP

to investigate into the purification, properties and biosynthetic regulation of a novel bacterial aryl dehalogenase An upper second class honours degree, or better, in biochemistry or biochemistry with chemistry is required, preferably with experience of enzyme purification. The post is tenable from 1 October 1985 in collaboration with PHLS-CAMR, Porton Down, under the joint supervision of Dr ARW Smith and Dr AV Quirk.

Further particulars and application form from the Staffing Officer, Thames Polytechnic, Wellington Street, London SE18 6PF, to be returned by 4 June 1985.

Thames Polytechnic is an equal opportunities employer. (6407)F

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF BIOCHEMISTRY

SERC-CASE STUDENTSHIP

Applications are invited for a SERC-CASE studentship to investigate the effects of synthetic plant growth regulators on sterol and gibberellin biosynthesis in whole plants and tissue cultures The project will be conducted in collaboration with Dr J Lenton, Long Ashton Research Station, Bristol. The interrelationships of the sterol and gibberellin pathways will be examined to determine if their regulation is a factor in the control of plant cell divisions and cell elongation. The student will gain experience in GLC and HPLC, mass spectrometry, plant cell culture, radiochemical and microscopy techniques. Applicants will be expected to have or to obtain, a first or upper second class Honours degree in Biochemistry, Chemistry or Botany. Further information can be obtained by contacting Dr L J Goad.

Applications including curriculum vitae and the names of two referees should be sent as soon as possible to The Registrar, The University, PO Box 147, Liverpool, L69 3BX.

Quote Ref: RV/267 (6380)F

QUEEN MARY COLLEGE

(University of London)

DEPARTMENT OF CHEMISTRY

RESEARCH STUDENTSHIPS

Applications are invited for the following Research Studentships for higher degree work under the supervision of Professor R. Bonnett. Research is expected to commence in August/September 1985.

1. Geochemical Studies on Porphyrins in relation to Coalification (supported by the British Coal Utilization Research Association Ltd.)

2 Synthesis of Porphyrin Sensitisers for Tumour Phototherapy (supported by Efamol Ltd.)

Applicants should have, or expect to obtain this year, a degree in chemistry with at least upper second class honours. Conditions for these studentships follow SERC guidelines. Application forms from Dr J R C Light, Chemistry Department, Queen Mary College, Mile End Road, London, E1 4NS to be returned by 17th June. (6352)F

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF CHEMISTRY

BIO-ORGANIC CHEMISTRY

SERC CASE STUDENTSHIPS

Applications are invited from graduates in Chemistry for two CASE Studentships Applicants must hold a first class or second class (Division 1) degree and will study for the degree of PhD.

(i) Anti-Cancer Uses of Synthetic Nucleoside Phosphonates in collaboration with Amersham International plc

The project involves the chemical synthesis of new derivatives of adenosine 5'-diphosphate, ADP. These are designed (i) to resist cleavage by phosphatase enzymes in vivo, (ii) to act as specific ligands for technetium-99m, and (iii) to penetrate tumour cells selectively.

The main part of the programme will be the synthesis of organic phosphonates of novel constitution and their incorporation into biological molecules; particular use of multinuclear high-resolution NMR and of MS facilities will be required.

(ii) Enzyme Inhibitors of the Shikimate Pathway in collaboration with ICI (Pharmaceuticals Division).

The project is directed towards the synthesis of antibacterials which function by blocking steps in aromatic amino-acid biosynthesis. Modelling will be based upon knowledge of reaction mechanisms and the application of computer graphics.

Applications or requests for further information should be made by writing respectively to (i) Dr G M Blackburn or (ii) Professor E Haslam at the Department of Chemistry, University of Sheffield, Sheffield S3 7HF. Quote ref: R258/G. (6365)F

WYE COLLEGE

(University of London)

DEPARTMENT OF BIOCHEMISTRY, PHYSIOLOGY AND SOIL SCIENCE

SERC CASE STUDENTSHIP

Applications are invited for a SERC CASE Studentship for research into the incorporation of foreign compounds (drugs, pesticides and other chemicals) into lipids, and the toxicological consequences of this phenomenon. The research will be carried out at Wye College, under the supervision of Dr P F Dodds, and at Shell Research Ltd, Sittingbourne, under the supervision of Dr D H Hutson.

Applicants should have, or expect to obtain, a first or upper second class Honours Degree in biochemistry or a related subject. An interest in lipid biosynthesis or drug/pesticide metabolism would be an advantage. The successful applicant will be required to register for the PhD degree at the University of London. Applications, comprising a full curriculum vitae and the names of two referees, should be made to The Registrar, Wye College (University of London), Wye, Near Ashford, Kent, TN25 5AH, from whom further information may be obtained (6349)F

THE UNIVERSITY OF WARWICK

DEPARTMENT OF BIOLOGICAL SCIENCES

POSTGRADUATE STUDENTSHIPS

Applications are invited from persons possessing, or expecting to obtain in June 1985, a suitable upper-second class Honours degree for the following eight studentships:

1 "The physiological basis of oligotrophy - morphological adaptation and selected cell type expression", Supervisor: Dr C S Dow; NERC Quota

2 "Carbon metabolism and growth of Marine Synechococcus species", Supervisors: Professor N G Carr/ Warwick and Dr I R Joint/NERC Institute for Marine Environmental Research, NERC CASE.

3 "Bioactalytic properties of ligninase from Phanerochaete chrysosporium"; Supervisor. Professor H Dalton, SERC Biotechnology.

4 "Molecular biological studies of infectious bursal disease virus"; Supervisor Dr M A McCrae, MRC Biotechnology.

5 "Reverse mutagenesis of Cowpea Mosaic virus", Supervisor. Dr D Evans/Warwick and Dr G P Lomonossof/John Innes Institute, SERC CASE.

6 "Neutralisation of influenza virus by IgM"; Supervisor Dr N J Dimmock/Warwick and Dr G C Schild/NIBSC; SERC CASE.

7 "Toxic product removal during microbial biotransformations"; Supervisors: Professor H Dalton/ Warwick and Dr P J Geary, Shell Research Centre; SERC CASE

8 "Ricin B chain as a carrier of antibodies into cells as a contribution to a more effective means of treating chemical poisoning"; Supervisors. Dr L M Roberts/Warwick and Dr A F Wright/ICI; SERC CASE

Applicants should indicate the project(s) of interest and send a cv and the names of two referees to the Executive Officer, Department of Biological Sciences, Warwick University, Coventry CV4 7AL Closing date 23rd May 1985. (6383)F

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF BIOCHEMISTRY

RESEARCH STUDENTSHIP

Applications are invited for a studentship, leading to the degree of PhD on "Endogenous and exogenous regulatory factors of protein degradation in normal and abnormal skeletal muscle", funded by the Muscular Dystrophy Group of Great Britain and Northern Ireland. Applicants should possess or expect to receive a 1st or upper 2nd class degree in Biochemistry, Molecular Biology or a related subject

Applications, together with the names of two referees, should be received as soon as possible by the Registrar, The University, PO Box 147, Liverpool L69 3BX

Quote Ref: RV/266 (6378)F

Medical Research Council Research Studentship (Partnership Award)

University Laboratory of Physiology, Oxford and the National Institute for Medical Research, Mill Hill, London

A 3-year M R.C. Studentship leading to a D.Phil. is available from 1st October 1985, for a project investigating contractile mechanisms in 'skinned' muscle fibres employing 'caged' ATP and the fluorescently labelled derivative of the calcium sensitive regulatory protein, troponin (TnC-DANZ). The training will involve the combination of physiology and biochemical methods, particularly the use of novel optical and laser techniques in muscle research, introduced by Dr C C Ashley and Dr. D.R. Trentham, F.R.S., the co-supervisors of the project.

The overall aim is to correlate mechanical and biochemical experiments on skinned muscle fibres with those on intact fibres in order to provide a clearer insight into the basic contractile mechanism and its regulation.

Applicants should have or expect to obtain a 1st or upper 2nd class honours degree, and have a background in physiology, biochemistry or physical sciences.

Applications including a CV and the names and addresses of 2 referees should be sent to Dr C.C. Ashley, University Laboratory of Physiology, Parks Road, Oxford OX1 3PT, as soon as possible. (6312)F

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL
(University of London)
DEPARTMENT OF ANATOMY AND BIOLOGY AS APPLIED TO MEDICINE,
Cleveland Street, London W1P 6DB
RESEARCH STUDENTSHIP IN PATTERN FORMATION

Applications are invited for a research studentship in the area of the cellular or molecular basis of pattern formation from October 1, 1985. Applications, or further enquiries, to Professor L Wolpert at the above address. (6394)F

UNIVERSITY OF LONDON
Institute of Neurology
DEPARTMENT OF NEUROCHEMISTRY
RESEARCH STUDENTSHIP

Applications are invited from undergraduates expecting to graduate with a 1st or upper 2nd class honours degree in biochemistry or molecular biology to undertake research with Dr F S Walsh. The project involves an analysis of the structure and function of the cell adhesion molecule N-CAM in skeletal muscle using a combination of cell and molecular biology techniques. For further information see EMBO J 4 623 (1985).

Applicaitons, containing the names and addresses of two referees, should be sent to Dr F S Walsh, Institute for Neurology, The National Hospital, Queen Square, London WC1N 3BG. (6390)F

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)
DEPARTMENT OF BIOCHEMISTRY
SERC CASE STUDENTSHIP
Drug Membrane Interactions

Applications are invited from students in physics, chemistry or biochemistry for an SERC Case Studentship in association with the Smith Klyne and French Company, Welwyn, to apply biophysical techniques such as laser flash photoplysis and FTIR spectroscopy to the studies of drug-membrane interactions.

Applicants should have (or expect to have) a First or Upper Second Class Honours degree or an equivalent qualification.

For further information please contact Professor D Chapman, Department of Biochemistry and Chemistry, Ground Floor, RFHSM, Rowland Hill Street, London, NW3 2PF (01-794-0500 Extn 3246) to whom applications giving the names of two referees should be sent as soon as possible. (6357)F

ST GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)
DEPARTMENT OF PHYSIOLOGY
MRC RESEARCH STUDENTSHIP

Applications are invited from individuals holding, or expecting to obtain, a good honours degree in Physiology or a related subject for a Research Studentship tenable in the Department of Physiology, St George's Hospital Medical School.

The successful applicant will work on one of several possible research projects. Further details are available from Professor J G Widdicombe, Department of Physiology, St George's Hospital Medical School, London SW17 0RE. (Tel 01-672 1255 x 4651), to whom applications with CV and names of two referees should be sent. (6377)F

UNIVERSITY OF LIVERPOOL
BOTANY DEPARTMENT
SERC/CASE RESEARCH STUDENTSHIP
Ion transport in a marine fungus

Applications are invited for a PhD research studentship to study ion transport in a marine fungus by tracer flux analysis and electrophysiocal techniques on intact hyphae and protoplasts. The studentship involves collaboration between the Botany Department (supervisor Professor D H Jennings) and the Marine Biological Association Laboratory at Plymouth (supervisor Dr C Brownlee). Candidates should have (or expect to have) a First or Upper Second Class Honours Degree or an equivalent qualification.

Applications with the names of two referees should be received as soon as possible by the Registrar, The University, PO Box 147, Liverpool L69 3BX, from whom further particulars may be obtained.

Quote Ref: RV/262/N (6354)F

UNIVERSITY OF NOTTINGHAM
DEPARTMENT OF MICROBIOLOGY
SERC CASE STUDENTSHIP
MEDICAL MICROBIOLOGY

An SERC CASE award is available in association with Glaxo Laboratories to study the phenomenon of 'tolerance' to penicillin in streptococci. Applications are invited for the studentship, which is expected to lead to the degree of PhD The student will be concerned with investigating factors influencing expression of the tolerance phenotype; its biochemical basis; its prevalence in clinical isolates; and its possible therapeutic implications. Applicants should possess, or shortly expect to obtain, a first or upper second class honours degree in microbiology and have a special interest in medical microbiology

Applications, with full curriculum vitae and the names of two referees, should be submitted to Dr David Greenwood, Department of Microbiology, University Hospital, Queen's Medical Centre, Nottingham NG7 2UH, not later than 31st May 1985. (6396)F

UNIVERSITY OF OXFORD
BOTANY SCHOOL
RESEARCH STUDENTSHIP
Calcium and Calmodulin in Higher Places

Applications are invited for a three year Studentship for studies on the regulation and localisation of the calcium-dependent regulator protein calmodulin in higher plants. The successful applicant will be expected to use immunological and related techniques and will work in a small group studying similar topics. Closing date for applications May 31st 1985.

For further details please contact: Dr D E Evans, The Botany School, South Parks Road, Oxford OX1 3RA. (6362)F

THE UNIVERSITY OF MANCHESTER
DEPARTMENT OF BIOCHEMISTRY
SERC/CASE STUDENTSHIP

Applications are invited for the above studentship tenable for three years from October 1st, 1985, and leading to a PhD degree. The project is concerned with 'Procollagen processing in the control of fibril formation' and will be supervised by Professor M E Grant & Dr D J S Hulmes (University of Manchester) and Dr C H J Sear, G D Searle (Research & Development), High Wycombe, Bucks. Applicants should have an interest in enzymology, electron microscopy and/or the application of physical techniques of biochemistry to the study of connective tissue disorders. They should have, or expect to obtain, a first or upper second class honours degree in biochemistry or biophysics. Applicants should write by May 17th, 1985, to Professor M E Grant, Department of Biochemistry, University of Manchester Medical School, Oxford Road, Manchester M13 9PT, enclosing a detailed curriculum vitae (in duplicate) and the names of two referees. (6399)F

UNIVERSITY OF LEEDS
DEPARTMENT OF BIOCHEMISTRY
SERC-CASE STUDENTSHIP
with
Shell Research Ltd
Sittingbourne

Applications are invited for the above position which involves a joint project between Dr D J Bowles at Leeds and Dr R L Lyne as the industrial collaborator. The research will concern the characterization of markers of embryogenesis for use in barley anther culture.

Candidates should have or expect to obtain a good Honours degree in Biochemistry, Biotechnology or Plant Sciences

Further information may be obtained from Dr D J Bowles (0532 431751 ext 7506). Applications with curriculum vitae and the names of at least two referees should be sent, by 31st May 1985, to Dr D J Bowles, Department of Biochemistry, University of Leeds, Leeds LS2 9JT (6344)F

THE QUEEN'S UNIVERSITY OF BELFAST
DEPARTMENTS OF BIOCHEMISTRY AND MEDICINE
RESEARCH STUDENTSHIP

Applications are invited for an MRC Partnership Award Research Studentship to undertake the chemical synthesis of analogues of fragments of peptide hormones and to study their biological and immunological properties. The studentship will be tenable from 1st October, 1985 for a period of 3 years provided that satisfactory progress is maintained. Candidates should have or be expected to have by July, at least a second class (upper division) honours degree in biochemistry or chemistry. Applications with curriculum vitae should be sent to Professor D T Elmore, Department of Biochemistry, Queen's University, 97 Lisburn Road, Belfast, BT9 7BL by 24th May, 1985. (6374)F

UNIVERSITY OF ABERDEEN
DEPARTMENT OF PLANT SCIENCE (BOTANY)
RESEARCH STUDENTSHIPS

Applications are invited for:

i. a SERC CASE studentship (with The Rowett Research Institute): Immunochemical studies on the plant cell cytoskeleton.

ii. a NERC CASE studentship (with ITE, Banchory Research Station): Early changes in soils under birch and heather.

iii a limited number of additional studentships which may become available in the fields of plant photophysiology, plant morphogenesis, ultrastructure of plant cells, stomatal physiology, recognition of plant chemotypes by insects, and plant cell and protoplast culture.

For further details write to Professor C H Gimmingham, Department of Plant Science, University of Aberdeen, St Machar Drive, Aberdeen AB9 2UD preferably before May 10th 1985. (6389)F

UNIVERSITY OF BRISTOL

DEPARTMENT OF MICROBIOLOGY

Applications are invited for

TWO SERC/CASE STUDENTSHIPS

ach of which is tenable for 3 years. ne project, in conjunction with fizer Central Research, will investiate adhesion of E coli to mammalian ceptors mediated by K88 pili. The cond project, in conjunction with nperial Chemical Industries, will vestigate expression of penicillin nding proteins in E coli.

Applicants should have, or expect obtain, a first or upper second class onours degree in a biological ience. An interest in molecular netics and/or bacterial cell mem-anes would be an advantage. urther details of both projects may e obtained from Dr Ian Chopra, epartment of Microbiology, The edical School, University Walk, ristol BS8 1TD to whom applitions, including a curriculum vitae nd the names of two referees should e sent. Applicants should indicate hether they wish to be considered r one, or both of the projects. losing date for applications May 1st 1985. (6361)F

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF SURGERY

Applications are invited for a

POSTGRADUATE STUDENTSHIP

work on an experimental study (in ivo and in vitro) of the pathways volved in the regulation of gall ladder emptying with special mphasis on cholinergic mechanisms.

Candidates, who must have a first lass or 2 1 honours degree, will be xpected to register for a PhD.

Applications, stating age, academic ualifications and experience, ogether with the names of two eferees, should be received as soon s possible by The Registrar, The niversity, PO Box 147, Liverpool 69 3BX. Quote ref RV/265/N. (6386)F

ST. MARY'S HOSPITAL MEDICAL SCHOOL (University of London) Norfolk Place, London W21 1PG

SERC CASE STUDENTSHIP

pplications are invited for a SERC ase Studentship in collaboration vith Shell Research Ltd (Dr D H Hutton) for research (leading to a PhD legree) into the effect of environmental conditions on the metabolism of hemicals by fish.

Applicants should have, or expect o obtain, a first or second class ionours degree in biochemistry or hemistry, and have an interest in hemical and environmental oxicology.

Applications, including the names of two referees should be sent as soon is possible to Dr P Millburn, Department of Biochemistry, at above address, from whom further particulars nay be obtained (tel 01-723-1252 ext 118) (6277)F

UNIVERSITY OF WALES COLLEGE OF MEDICINE

DEPARTMENT OF PHARMACOLOGY AND THERAPEUTICS IN ASSOCIATION WITH MERCK SHARP AND DOHME RESEARCH LTD

SERC RESEARCH STUDENTSHIP

Applications are invited for the above 3-year studentship from candidates with or expecting a good Honours degree. Our preferred candidate will have an interest in experimental in vitro pharmacology, computer on-line data collection and interfacing, mathematical data analysis and modelling and have significant undergraduate experience in at aleast one of these.

The project will investigate the intrinsic modulation of neurotransmission in autonomically innervated tissues using microcomputer techniques to analyse drug effects on responses to field stimulation.

Applications, in the form of a curriculum vitae with the names and addresses of two referees, should be sent to the Registrar and Secretary, University of Wales College of Medicine, Heath Park, Cardiff CF4 4XN, from whom more detailed information is available (Tel No 0222-755944 Ext 2296). (6360)F

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF ANATOMY & EMBRYOLOGY

Applications are invited for a

SERC STUDENTSHIP

to work on the organisation of the visual cortex using anatomical, physiological, immunohistochemical and computer imaging techniques. Applicants should have, or expect to receive, a good honours degree and register for the PhD of the University of London

Applicants should write to Professor Zeki, Department of Anatomy & Embryology, University College London, Gower Street, London WC1E 6BT, from whom further details may be obtained. (6395)F

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF ZOOLOGY

SERC CASE STUDENTSHIP

Trematode larvae and the snail immune response

Applications are invited from recent graduates or those about to graduate in a Biological Science for a CASE studentship leading to a PhD. The project, in collaboration with Dr V R Southgate (British Museum, Natural History), will investigate the cellular basis of host-parasite interactions between the blood fluke Schistosoma spp and the snail Bulinus spp both in vivo and in vitro.

Applications with a curriculum vitae and the names of 2 referees should be sent to T M Preston, Zoology Department, University College London, Gower St, London WC1E 6BT from whom further information may be obtained. (6393)F

UNIVERSITY OF CAMBRIDGE

SERC CASE RESEARCH STUDENTSHIP

Development of Laser-Ionisation Mass-Analysis (LIMA) as an Organic Microprobe in Chemical and Biological Systems

Applications are invited for an SERC CASE Research Studentship in collaboration with Shell Research Ltd, Sittingbourne, Kent, leading to the PhD degree.

The project is of a highly interdisciplinary nature, entailing the interpretation of organic mass-spectra, the preparation of biological materials, modification of computer software and an interest in physical instrumentation. Most of the work will be done on a new Cambridge Mass Spectrometry Ltd. LIMA instrument in the Department of Metallurgy and Material Science, Cambridge, with facilities for comparative SEM, X-ray microanalysis and FAB-MS work at Shell Research Ltd, Sittingbourne.

Enquiries are invited to Dr M J Southon, Department of Metallurgy and Materials Science, University of Cambridge, Pembroke Street, Cambridge CB2 3QZ, from whom further particulars may be obtained (tel 0223 65151). (6335)F

UNIVERSITY OF LEEDS

DEPARTMENT OF PURE AND APPLIED ZOOLOGY

MAFF STUDENTSHIP

The above studentship is available from October 1985 for up to 3 years on the following topic.

The effects on the environment of pesticide use on grassland.

Applications are invited from graduates or final year students in agricultural zoology; applied biology or a related discipline.

Informal enquiries may be made to Dr J S Bale (Tel 0532 431751 ext 7423).

Applications in the form of a curriculum vitae with the names and addresses of two referees should be sent to Dr J S Bale, Agricultural Sciences Building, The University, Leeds LS2 9JT by 20 May 1985. (6345)F

UNIVERSITY OF READING

DEPARTMENT OF PHYSIOLOGY AND BIOCHEMISTRY

Applications are invited for an

SERC/CASE STUDENTSHIP

shared between this department and the Tolworth laboratory (MAFF). The project is on the use of esterases as indicators of the exposure of birds to pesticides

Candidates should have a good honours degree (1st or 2(i)) in Biochemistry or a related discipline, and some interest in field work.

Further details may be obtained from Mr C H Walker, Department of Physiology and Biochemistry, University of Reading, Whiteknights, Reading RG6 2AJ, to whom applications and the names of two referees should be sent. (6385)F

UNIVERSITY OF KEELE

RESEARCH DEPARTMENT OF COMMUNICATION AND NEUROSCIENCE

RESEARCH STUDENTSHIPS

Research studentships leading to the degree of PhD are available in this interdisciplinary postgraduate research Department in the following areas of study:

1 Auditory physiology: frequency selectivity, pitch, intensity, animal models of deafness, tinnitus, clinical applications, rehabilitation (Professor E.F. Evans).

2. Visual neurophysiology: retina, cortex, pattern, texture, motion, relative motion; neural correlates of after-effects (Dr P. Hammond).

3 Speech processing: human perception, computer synthesis and recognition, lip-reading aids (Dr. W A Ainsworth).

4 Visual psychophysics: pattern recognition, motion acuity, mathematical modelling, colour vision, clinical applications (Dr. D H Foster).

5 Neuroanatomy: ultrastructure of auditory system in normal and deaf animals, dye tracing of physiologically identified neurones (Dr. C.M Hackney)

6. Visual evoked potentials: information processing in human visual cortex (Dr. D A Jeffreys).

7. Clinical auditory psychophysics and evoked responses: diagnosis, prevention and amelioration of sensorineural hearing loss (Dr G.F. Pick).

8 Auditory psychophysics: pitch and space perception, frequency-sweep adaptation, frequency analysis, cochlear echoes, tinnitus (Dr. J.P. Wilson).

Interested students with a first or upper second class honours degree in an appropriate discipline are asked to write to:

Dr. D. .H. Foster,
(Postgraduate Admissions),
Department of
Communication &
Neuroscience,
University of Keele,
Keele,
Staffordshire ST5 5BG.

(6347)F

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF GENETICS

SERC/CASE STUDENTSHIP

Applications are invited for a SERC/CASE studentship leading to the degree of PhD. The project is concerned with molecular genetics and gene cloning in the methylotrophic yeast Hansenula polymorpha and will be carried out in association with Unilever plc. The successful candidate will be expected to spend a period in Unilever's laboratories in Holland. Applicants should possess, or expect to obtain, a good honours degree in a relevant subject.

Applications, to arrive before 31 May 1985 (including a full curriculum vitae and names and addresses of two referees), should be sent to Dr P E Sudbery, Department of Genetics, the University, Sheffield S10 2TN, from whom further details may be obtained (telephone 0742-78555 ext 6186). Quote ref: R261/G. (6403)F

FELLOWSHIPS

UNIVERSITY OF GUELPH
UNIVERSITY FELLOWSHIPS

The College of Biological Science is emphasizing its Research and Graduate Programs and invites applications from individuals interested in competing for NSERC University Fellowships Candidates are reminded that they would be eligible for consideration for any tenure track position available following their appointment
The following are the areas of research emphasis in the various departments·

BOTANY
Growth and development of plants
MICROBIOLOGY
Microbial pathogens of fish
Fermentation technology
Molecular biology of virus reproduction
MOLECULAR BIOLOGY AND GENETICS
Cell and molecular biology of gene expression
Development biology
DNA replication and genetic recombination
Human genetics
NUTRITION
Nutritional immunology
Nutritional toxicology
Nutritional biochemistry
ZOOLOGY
Dynamics of marine invertebrate communities
Developmental and reproductive biology
SCHOOL OF HUMAN BIOLOGY
Human physiology
Physical anthropology
Ergonomics
Quantitative biomechanics/bioengineering
Human morphology and human and medical genetics
Successful candidates would have the opportunity of participating in both the undergraduate and graduate teaching programs.

Applications, including a curriculum vitae, and the names of three referees should be forwarded, by August 1st, to: Bruce H. Sells, Ph.D., Professor and Dean, College of Biological Science, University of Guelph, Guelph, Ontario, Canada N1G 2W1.
(NW1739)E

NUFFIELD FOUNDATION
ONE YEAR SCIENCE RESEARCH FELLOWSHIPS

The Nuffield Foundation is offering to University Lecturers in Science and Applied Science Departments a number of one-year research fellowships to be awarded competitively at the end of 1985 and to be held during the academic year 1986-87. The objective is to enable younger university lecturers to be freed from teaching and administrative duties for one academic year. Preference will be given to applicants under the age of 40. Awards will cover the cost of replacement teaching (up to the fourth point on the lecturer scale) and will include an allowance for research expenses.

The closing date is 11th October 1985 and further particulars may be had from the Director, Nuffield Foundation, Nuffield Lodge, Regent's Park, London NW1 4RS.

This scheme is only open to applicants from Institutes within the United Kingdom. (6332)E

UNIVERSITY OF ABERDEEN
DEPARTMENT OF MICROBIOLOGY
POSTDOCTORAL FELLOWSHIP IN THE GENETICS OF ENERGY TRANSDUCING SYSTEMS OF ESCHERICHIA COLI

A two-year postdoctoral research fellowship is available in the laboratory of Dr I R Booth from I October, or as soon thereafter as possible The SERC funded project is to study genetic and bioenergetic aspects of the role of the eup gene product in the transduction of energy in E coli.

Salary on the Range 1A scale for Research and Analogous Staff, £7,520 to £12,150 per annum, with appropriate placing

Further particulars and application forms from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 7 June 1985. (6387)E

UNIVERSITY OF WATERLOO, DEPARTMENT OF BIOLOGY
NSERC UNIVERSITY RESEARCH FELLOWS

The Department of Biology, University of Waterloo, invites applications for NSERC University Research Fellowships in the following areas of research interest (i) population genetics with emphasis on the genetic structure and dynamics of real as opposed to theoretical populations, (ii) protein chemistry or biochemistry (including immunology). Applications in other areas will also be given serious consideration Successful candidates will be expected to establish a vigorous research program and participate in teaching both undergraduate and graduate students.

A curriculum vitae including names of three referees should be sent to Dr. J.E. Thompson, Chairman, Department of Biology, University of Waterloo, Waterloo, Ontario, Canada, N2L 3G1. Prospective candidates should examine the NSERC Awards Guide 1985-86, paragraph 196 on page 54 for details In accordance with Canadian Immigration requirements, this advertisement is directed to Canadian citizens and permanent residents. (NW1740)E

POSTDOCTORAL FELLOWSHIP

Positions are available in an NIEHS training program for multidisciplinary research at Yale Medical School in environmental toxicology and physiology in the following areas· biochemistry, epidemiology, pathology, pharmacology, physiology, and toxicology The positions are open to U S citizens or permanent residents with M.D , D V M., Ph D., or equivalent degrees Applicants should send curriculum vitae with two references, and specify their area of interest to. **Arthur B. DuBois, M.D., John B. Pierce Foundation Laboratory, Yale School of Medicine, 290 Congress Avenue, New Haven, Conn 06519.** *Affirmative Action/Equal Opportunity Employer.*
(NW1730)E

MASSEY UNIVERSITY
Palmerston North,
New Zealand
UGC POST-DOCTORAL FELLOWSHIPS

Applications are invited for Postdoctoral Fellowships in 1986 to be funded and awarded by the University Grants Committee and tenable within Massey University

Awards may be made for one year or for three years.

Applications from candidates wishing to work in any department of the University will be considered, but in making the awards the University Grants Committee will give priority to current growth research areas such as biotechnology, genetic engineering, electronics, engineering, chemistry etc

The emolument payable will be at a rate to be determined but not exceeding the lowest step on the University scale for lecturers (currently NZ$23,622 per annum).

Applicants should have completed the requirements for the award of the degree of Doctor of Philosophy.

Further details of the position, together with conditions of appointment, may be obtained from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University, with whom applications close on 31 July 1985 (W1843)E

UNIVERSITY OF LEICESTER
DEPARTMENT OF PHARMACOLOGY AND THERAPEUTICS
MERCK SHARP & DOHME NEUROSCIENCE RESEARCH FELLOWSHIP

Applications are invited for a MSD Neuroscience Research Fellowship to study cholinergic receptor-effector mechanisms in brain. The project involves receptor labelling and an assessment of receptor-effector coupling by examination of cyclic nucleotide and inositol phospholipid metabolism in brain. Applicants should have, or shortly expect to have, a PhD and possess suitable experience in pharmacology/biochemistry/neurobiology. Some experience of discrete cerebral lesioning or tissue culture would be an advantage. Although this position is with Professor S R Nahorski's research group in Leicester, it is possible that a short period may be spent at the MSD Neuroscience Research Centre, Harlow, with Dr L L Iversen The Fellowship is from 1st October 1985, or nearest convenient date, and is for a period of one year in the first instance and for which funding may be extended for a further two years.

Salary is on the scale £7,520 -£12,150 (Research 1A).

Additional information can be obtained from Professor S R Naborski, Department of Pharmacology and Therapeutics, Medical Sciences Building, University of Leicester, University Road Leicester, LE1 7RH, UK, (0533 551234, Ext 361) to whom applications, including CV and names of two referees, should be sent. (6306)E

IMPERIAL CANCER RESEARCH FUND
RESEARCH FELLOWSHIP

A post-doctoral, three year appointment is available in our Oncogene Co-operation Cancer Development Laboratory to work with Dr H Land on projects invólving Isolation of myc-like genes from tumours and normal cells.

Salary range £10,220 to £12,505, entry according to qualifications and experience. Further details are available from Ms S M Hurley, Imperial Cancer Research Fund, PO Box No 123, Lincoln's Inn Fields, London, WC2A 3PX, telephone no: 01 242 0200 ext 305.

TISSUE POLYPEPTIDE ANTIGEN

A VALUABLE TOOL IN CANCER RESEARCH AND TREATMENT

Tissue Polypeptide Antigen (TPA) is a protein related to cytoplasmic intermediate filaments of cells in interior epithelium. Since carcinomas originate in interior epithelium, TPA is therefore present in carcinoma cells. Serum or plasma TPA measurements are useful in monitoring tumour activity; its character as a specific label of interior epithelial cells also makes immunohistochemical staining of TPA an important technique, both for research and in routine therapy.

Two TPA positive cells from a transitional cell carcinoma of urinary bladder epithelium invading a deeper layer of the bladder wall. PAP/haematoxylin staining. Microphotograph by courtesy of Dr P. Oehr, University Clinic, Bonn.

TPA staining of HeLa cell by indirect immunofluorescence. The cellular distribution of TPA corresponds to that of intermediate filaments. Microphotograph by courtesy of Dr V. Björklund, National Bacteriological Laboratories, Stockholm.

TPA products available from Sangtec Medical:

1. Detection in serum and plasma by Radioimmunoassay using Prolifigen® RIA kit.
   For monitoring cancer therapy and to detect tumour recurrence.
2. Detection in tissue by immunohistochemistry using rabbit anti-TPA:B1 antiserum.
   Evaluation of tumour invasivity; to establish if tumour excision is complete; to assess metastasis in lymph nodes and bone marrow; to identify origin of undifferentiated tumour tissue.

BIOSYSTEMS UPDATE

Introducing the high performance, low cost, fully automated DNA Synthesizer.

The new Model 381A DNA Synthesizer optimizes the efficient phosphoramidite chemistry to reliably and economically produce high quality oligonucleotides.

Automatic rinsing and priming of reagent lines when new chemicals are added, menu-driven software and stable, prepackaged reagents make the 381A easy to use.

Results *and* Affordability

The new Model 381A produces high purity, defined-sequence oligonucleotides quickly and economically. It delivers routine coupling yields of 98–100% and the capability to synthesize oligonucleotides with more than 100 bases.

The 381A is a *complete* instrument-reagent system with the proven chemistry and precision design that have made Applied Biosystems the world leader in synthesis technology. Affordably priced, the 381A brings every researcher the speed and reproducibility of automated DNA synthesis with the convenience of an in-lab instrument.

Advanced Capabilities

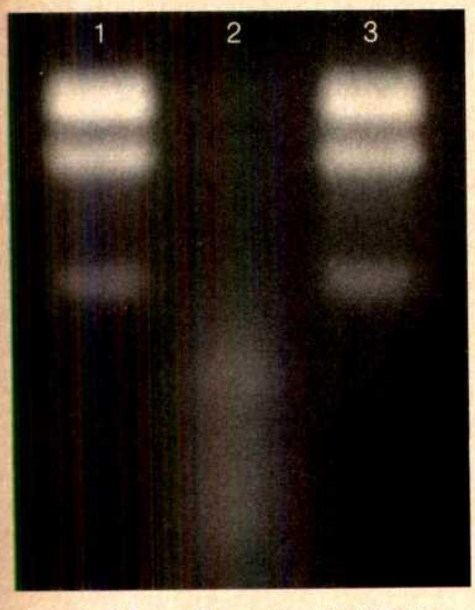
The 381A can produce 50 to 100-mers providing greater flexibility in gene synthesis strategy by minimizing the number of purifications and ligations. With the efficient phosphoramidite chemistry, probes and primers can often be used without purification. Specific primers for Sanger dideoxy sequencing can be ready for use in less than 18 hours.

Production of mixed probes can be accomplished without any premixing of bases, and the addition of unusual bases can be completely automated. Small amounts of probes and primers or up to 10 mg of DNA for physical studies can be made economically and automatically with no hardware modifications.

Fully Programmable

The 381A can be operated with the standard synthesis cycle or used to develop and store new chemistry methodologies incorporating existing or user-defined functions. Users can optimize cycles for up to five different nucleotides or derivatives. Integral battery with automatic re-start preserves synthesis parameters and user-designed cycles when power is interrupted.

Immediate Delivery



Compare and you'll agree: The 381A is a remarkable performance/price value. Your local Applied Biosystems representative has all the information for immediate purchase and shipment. Contact us at one of the offices listed below or key reader service number **08**.

RNasin®
Ribonuclease Inhibitor

We added RNase to our RNA and got full protection.

Analysis of Brome Mosaic Virus (BMV) RNA by agarose gel electrophoresis after the following treatments:

1. Control BMV RNA;
2. BMV RNA treated with RNase A;
3. BMV RNA treated with RNase A in the presence of **RNasin** ribonuclease inhibitor.

RNasin® ribonuclease inhibitor is a protein isolated from human placenta which specifically inhibits RNases. It functions by binding tightly to a wide spectrum of RNases. It can be very useful wherever strong RNase inhibition may be essential to protect your RNA.

When you use RNasin® ribonuclease inhibitor you get documented performance.

Since its introduction in 1981 by Promega Biotec, **RNasin** ribonuclease inhibitor has been used world-wide in a variety of applications. This highly versatile protein has been demonstrated to:

■ **Improve cDNA synthesis.** Both the size and yield of synthesized cDNA is improved (1, 2).

■ **Improve protein translation performance.** The yield of larger proteins from wheat germ translation systems can be improved (3). The full length 200,000 dalton protein of Encephalomyocarditis virus can be synthesized in a wheat germ system only when **RNasin** ribonuclease inhibitor is present (16).

■ **Increase *In Vitro* RNA synthesis.** Nucleoli isolated from Erlich ascites tumor cells synthesize larger RNA, and Erlich nucleolar RNase is inactivated. (4).

■ **Improve *In Vitro* virus replication.** *In Vitro* synthesis of plus strand Blacl Beetle Virus (BBV) RNA is possible only after the addition of **RNasin** ribonuclease inhibitor (6).

■ **RNasin ribonuclease inhibitor alsc protects your RNA in other enzym reactions where RNase has prove to be a problem.** These include the reactions of:

- DNase
- RNA capping and tapping
- Poly A polymerase
- Terminal transferase

■ **Help prepare RNase-free antibody. RNasin** ribonuclease inhibitor can be used to remove RNase from antibody preparations by affinity chromatography (18, 17).

■ ***Enhance yields from Riboprobe™ Gene Analysis System RNA synthesis reactions. RNasin*** *ribonuclease inhibitor is routinely used in these transcription reactions to ensure the preservation of the fu length, single-stranded RNA transcripts that are made. Such transcrip are used as high specific activity probes in blot hybridizations (19), solution hybridizations (20, 21), and in situ hybridizations (22, 23), or as full length genomic RNA processing substrates (24, 25).*

NATURE VOL. 315 16 MAY 1985

COVER

A worker desert ant, *Cataglyphis fortis*, running at full speed, holding the abdomen vertically to decrease the moment of inertia during high-velocity turns. On page 228, it is demonstrated that these ants use interocular transfer of information when they navigate by the pattern of polarization in the sky but not when they orientate by landmarks.

Hot on delivery...

...cold on arrival

When you order molecular biologicals from Pharmacia you'll find we're pretty hot on delivery.

We'll dispatch your order as soon as we get it, packing it carefully in wet or dry ice.

Now our enzymes are supplied in screw cap mini vials with new waterproof labels, and will easily fit into your centrifuge tubes and freezer trays.

At Pharmacia Molecular Biology Division that's all part of the service. We realize that the success of an experiment depends on the quality of the products used and the speed at which you get them. With us you'll find that the only thing kept on ice is your product – not your experiment.

Contact us today and we'll send you our free catalog with details of over 800 molecular biologicals.

Pharmacia... your partner in molecular biology.

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

nature

NATURE VOL. 315 16 MAY 1985

President Reagan and Mr Perle

The US administration seems to be speaking with two voices on arms control. Mr Richard Perle, the hard man from the Pentagon, should be the one to opt for moderation.

THE assumption that statesmen have no time to read the newspapers seems to be gaining ground. That, at least, is the simplest explanation why President Ronald Reagan (at Strasbourg) and Mr Mikhail Gorbachev (in Moscow) used the fortieth anniversary of the ending of the Second World War in Europe to tell their separate audiences of the other's malevolence. Although much of the rhetoric may have been directed at Western Europe in general, and not at the European Parliament (Mr Reagan) or a celebratory parade in Moscow (Mr Gorbachev), both declarations will have helped chiefly to reinforce the belief that nobody is in much of a mind to win agreement at the negotiations of strategic arms soon to resume at Geneva. But if the negotiations are again a failure, people may well remember what the superpower leaders were saying last week.

As when a bridge-player can win only when some vital card is on his left, he had better play on that assumption, so it is prudent to suppose that the rhetoric masks a more benign state of affairs. But then the question arises of the remarks of Mr Richard Perle, assistant secretary at the US Department of Defense, who was explaining to a congressional committee again last week why, in general, arms control agreements favour the Soviet Union rather than the United States, why the Soviet Union can be relied upon to break any agreement that may be signed and why, in particular, the United States need not be too meticulous in observing the spirit of the SALT II treaty, the unratified agreement which limits the numbers of strategic missiles which each side may deploy, and which has been broadly followed since it was signed in 1979. Mr Perle, who knows well enough that other people read the newspapers, has never hidden his belief that arms control is a fruitless pursuit. But making such a song and dance about it is bound to give Soviet readers the impression that it is a part of the US administration's policy, which is presumably untrue.

Mr Perle's views nevertheless deserve attention. There is a sense in which agreements favour the Soviet Union. The US system is open to public scrutiny, much of it relentlessly vigilant, while the Soviet system is, by comparison, secret. So, in principle, the Soviet Union can sign an agreement and then promptly break it. That is what Mr Perle suggests. The snag is that the Pentagon's attempts so far to prove Soviet cheating on arms control agreements are thoroughly unconvincing. Allegations of the proxy use of toxic chemicals in South-East Asia are dubious. The allegations of breaches of the threshold test-ban treaty are only marginally convincing, given the uncertainties of seismic interpretation. The surest transgression so far established is the Soviet construction of a phased-array radar at Krasnoyorsk in central Siberia, apparently a breach of the anti-ballistic missile treaty of 1972 (which has been ratified). The United States has a perfect right to demand a better explanation than has been given so far. What Mr Perle leaves out of his calculations is the certainty that the Soviet Union, secretive though it may be, would nevertheless be seriously harmed if it were shown unambiguously to have cheated on a solemn agreement.

In reality, the Soviet Union (like the United States) has a creditable record on compliance with agreements on strategic arms, and did not complain that the US underground test that vented radioactivity to the surface was a violation of the oldest (1953) agreement on nuclear weapons. The agreement not to place nuclear weapons ("weapons of mass destruction") in space has been kept. If anything, the Soviet Union has been more meticulous than the United States in observing the provisions of the Non-Proliferation Treaty (1968) that its partners in the civilian trade in nuclear materials would not be allowed to fashion nuclear weapons from them. Not that either of the superpowers would relish the emergence of other nuclear weapons states. The difference between them is merely that the United States has a more vivid interest in the commercial benefits of the trade, which are often then frustrated by US domestic legislation.

A more accurate version of Mr Perle's conviction that the Soviet Union will always cheat is therefore that the Soviet Union will always honour the letter of its agreements, but will exploit to the full the opportunities it is not formally denied. This, it might be held, is why western Russia was thickly populated with SS20 missiles in the late 1970s, in defiance of the spirit but not the letter of the SALT I treaty (1972), which says nothing about missiles of intermediate range.

Mr Perle now says that the new Soviet missile, called the SS25, which has begun to make its appearance on the ground, is a violation of SALT II because it is an essentially new device, which would be forbidden by the treaty, even though its external dimensions do not differ much from those of the much earlier SS13. Mr Perle's difficulty is that while the treaty allows each side to deploy one new type of long-range missile, the definition of what is new and different is determined (in article IV.8) primarily by the external dimensions (plus or minus 5 per cent). The Soviet Union, which appears to have offered to retire as many old missiles as the new versions it may introduce in the months ahead, may be legally right to claim the SS25 is within the treaty. The issue matters to the United States, which will have to decide in September whether the sea-trials of the new *Trident* submarine will require it to retire an ageing *Polaris* boat. What Mr Perle might gracefully acknowledge is that the faults lie not primarily with the Soviet Union, but in the language of SALT II, which has been overtaken by events in just seven years. Geneva, now, should be partly about the redrafting of this clumsy treaty and partly about its extension to missiles of intermediate range. This should preferably be done before the treaty runs out at the end of December — a deadline specified on the assumption that, by then, there would be more meaningful treaties on the books.

SALT II is therefore not a treaty that people should struggle to see ratified. If that were Mr Perle's case, he would be generally applauded. Where he goes wrong is where he goes further, in saying that the existence of this informal scrap of paper is of no

Biological manuscripts

From the beginning of next week (20 May), Miranda Robertson, Biological Sciences Editor of *Nature*, will be based in the Washington office of *Nature*. Manuscripts offered for publication may be sent, as at present, to either the London or the Washington office; with the benefit of good communications, the speed with which manuscripts are dealt will be independent of the place at which they are received. But authors are asked please in future to send **four copies of manuscripts** intended for publication (one for each office and two for referees). □

significance — that it counts for nothing more than the anti-ballistic missile treaty, now threatened by the star wars programme. The assumption that these documents count for nothing is a psychological mistake. The most striking evidence to the contrary is that the two superpowers, while knowing that the treaties lack the force of law, have nevertheless chosen to behave as if the treaties were binding on them. But to the extent that the states of Western Europe are interested parties, these scraps of paper are the only assurance they have that events will not get out of hand.

It would serve Mr Perle's purpose just as well, and that of the US administration at the same time, if he were to turn the other cheek and challenge the Soviet Union by demanding that the US Congress should ratify the threshold test-ban treaty in its present form, which forbids the testing even underground of nuclear warheads exceeding the equivalent of 150,000 tonnes of TNT. This, broadly speaking, is the practice to which the superpowers have kept since 1972. Congress in its present mood would sign with very little persuasion. (Only the Senate would matter.) The benefits would be that the Soviet Union would be required to produce a stack of seismic data with the help of which suggestions of violations could be more accurately assessed, even retrospectively. If Mr Perle's suspicions are correct, they would be confirmed. If they are not, sweetness and light would spread. Either way, the fear would be dispelled that the US administration is divided on arms control, showing up at Geneva diligently while thinking like Mr Perle. □

Football squalor

The deaths at a British football game should be an invitation to economic realism.

THE British government is in a tragic dilemma over the game of soccer, otherwise association football. Last Saturday, 53 people were killed (with more than a dozen people still missing) when a wooden structure in which several thousand had been sitting caught fire and burned to a cinder in the Yorkshire city of Bradford. But for most of the winter, the government has been worrying not simply about the British economy but about the phenomenon of soccer hooliganism, the way in which bands of football supporters attack each other, or the other side's players, or sometimes the officials who try to ensure fair play. Football crowds have been a worry for British governments ever since 1972, when even more people were killed than last weekend during a stampede at a football ground in Glasgow.

The causes of last weekend's fire and of the long-standing hooliganism of football crowds are linked. British professional football, long since a spectator sport, is by legend the poor man's entertainment. So it was before the invention of the television, since when attendance at football matches has been falling steadily. Now, it is more accurately a poor professional's living. All but the best of football teams scrape by on a shoestring. Their grounds are squalid places. Sitting room is limited and expensive. Most have to stand for a couple of hours at a stretch, often crowded together in a way almost calculated to provoke violence. Yet so parlous is their financial condition that more than a third of the football grounds in England and Wales have been exempted from the safety regulations made law in 1975.

The simple question prompted by the death of 53 people in a tinderbox is whether it makes sense for a British government which has other things to worry about to shelter from economic reality commercial organizations which cannot afford to protect their customers from avoidable risks, let alone provide them with an environment which induces them to watch the game and not attack each other. Whether a country of 50 million people needs more than 100 professional football teams in the top flight (counting those in Scotland) is a matter that should be determined by market forces and not the government. If the outcome were that some were at a loose end on Saturday afternoons, and forced as a consequence actually to play the game they would otherwise be watching, that might be no bad thing. □

Patent rights

Two years late, British academics are to have title to patents arising from inventions.

Two years have passed since the British Prime Minister, Mrs Margaret Thatcher, promised publicly that inventions generated with public support would no longer have to be offered for exploitation to the National Research Development Corporation (NRDC), but only this week has the government decided that the time for changing the present system has actually arrived. From now on, universities will be free to exploit their own inventions, whether or not they arise from research grants awarded from public funds. NRDC will remain in being (as part of what is now called the National Enterprise Board), and may paradoxically be even more ready in the future than in the past to exploit inventions offered by academic researchers, not least because there will be competition. Individual researchers are likely to be excited (and surprised) by the details of the new arrangements, which should provide them with a powerful incentive to market their discoveries, but their institutions will also benefit, on paper at least. So will British academic research now be further transformed by people's ambitions to get rich?

To a first approximation, the answer is no. The new arrangements for the exploitation of British inventions are no different in principle from those in force in the United States since 1972. Before British academic researchers and their institutions start counting their golden geese (to mix two metaphors), they had better reflect on the frequently disappointing experience of US universities, which have often found that the right to the independent exploitation of innovations is often exercised only with difficulty, while the duty to do so (implied by the US legislation) may be onerous. For what many US universities have discovered is largely what NRDC has been saying almost since its foundation in 1947 — that only a tiny proportion of academically-based patents become money-spinners. A large national organization, with a monopoly right of first refusal, can hope to cover the cost of protecting ideas taken onto its books by the proceeds from a few money-spinners. Smaller organizations, even whole universities, are by definition less able to cover their risks.

Even so, it is right that there should be a change in the arrangements in force in Britain. Although NRDC has never managed to demonstrate the touching belief of its founders that Britain was awash with patentable inventions going to waste, and while its work over the decades has been creditable, it has also accumulated a rich fund of ill-will among academic researchers who consider, rightly or wrongly, that their bright ideas have been too often overlooked. The truth, of course, is that no single organization can hope to make consistently wise decisions in such a vast field. The best approach is bound to be one in which different organizations make independent appraisals of novel developments and then agree to back those they fancy with tangible resources, both money and management. With the persistent pressure on university research funds, and the change in general attitudes towards the exploitation of new ideas, ending the corporation's monopoly right will do much more good than harm.

The consequences of this change for the character of what happens in British academic laboratories is unlikely, in the short run, to be profound. To be an acknowledged success as a scientist or engineer will continue to be an important if no longer a paramount consideration. Moreover, NRDC will retain an active interest, and indeed is plainly planning (with government help) to strengthen its links with university researchers. The most likely change is that there will be other venture capitalists scouring the academic laboratories for exploitable innovations, while established companies will have a further incentive to forge academic links, perhaps with particular departments, by offering help with patent protection. The danger, probably not at this stage serious, is that some universities or parts of them may become so immured in particular relationships that they will cease to be impartial sources of help and advice for industry at large. That is an issue to which university administration should urgently pay attention. □

US–Soviet exchanges

Academy divided over new agreement

Washington

THE US National Academy of Sciences (NAS) is coming under increased criticism for negotiating a renewed scientific exchange agreement with the Soviet Academy of Sciences last January. Details of the agreement, which is still awaiting ratification by the Soviets, are being kept secret by the academy, which has intensified the uneasiness of groups working on behalf of Soviet refusniks and dissidents.

Shortly before the NAS annual meeting last month, a letter, signed by Christian Anfinsen, Paul Flory and Arno Penzias, was sent to all academy members, challenging both the wisdom and the morality of the move to reestablish ties. (The letter was subsequently published in *Science* **228**, 530; 1985). Anfinsen *et al.* asked what had changed "to explain the about-face from the moral stance of 1980", when NAS broke off relations with the Soviet Academy in protest at the internal exile of Andrei Sakharov.

The three said Sakharov's condition had in fact worsened, and, citing NAS's own Committee on Human Rights, that there had been many new arrests of scientists. "To have held the negotiating meeting in Moscow", they concluded, "makes it hard to avoid an unfortunate hat-in-hand image."

A sharper challenge has come from Sakharov's son-in-law, Efram Yankelevich, who is living in the United States. After seeing Dr Frank Press, president of NAS, Yankelevich wrote an impassioned letter, taking Press and the academy to task in the strongest terms for having abandoned his father-in-law. The letter has been widely circulated within the scientific community.

Finally, Richard Perle, the hard-line Assistant Secretary of Defense for international security policy, broke government silence on NAS's actions with a strong criticism of his own. Speaking at a press forum arranged by the Scientists Institute for Public Information in Washington, Perle said that he was "disappointed that NAS is plunging ahead" with renewing exchanges. He argued the familiar administration line that the Soviets gain more from such exchanges than does the United States.

There is little doubt that Press has the support of the NAS membership, but these attacks have put him on the defensive. Press said last week that the differences between him and his critics amounted to a disagreement over tactics for aiding the refusniks and dissidents. He argued that, without face-to-face contacts, NAS's leverage is "non-existent". He said that "sending telegrams that are never even acknowledged may ease people's consciences, but there's no proof they've done any good".

Asked about reports from refusniks that their situation has worsened since he signed the agreement in Moscow (see the letter from Solomon Al'ber in *Nature*, 2 May, p.10), Press said that he had heard "contrary information" from his sources. And a source familiar with the negotiations said that NAS had demanded considerable concessions, including mention of the Helsinki accord in the text of the protocol. Academy officials have also let it be known that a part of the NAS delegation that went to Moscow met with refusniks there; Press himself did not, however.

As for Perle's criticisms, Press said that "he should have asked me what happened in Moscow before he made those remarks", remarks Press characterized as "intemperate".

Press said that Perle had not taken advantage of the opportunity to be briefed about the agreement (as were State Department officials and the US Ambassador in Moscow).

Press also rejects complaints about the secrecy of the document. He said that it is still in draft form and cannot be made public until negotiations have been completed and the text has been agreed by the Soviets.

Stephen Budiansky

Correction

IN the graph illustrating the percentage of approved extramural research grants that are awarded by the National Institutes of Health (*Nature* May 9, p.88), the units on the right-hand axis were incorrectly specified. The range covered should have been from 30 per cent to 60 per cent, not from 3 per cent to 6 per cent. □

Sakharov

Resignation from Soviet academy

Ottawa

THE Ottawa review conference of human rights performance by the 35 signatory countries of the Helsinki Final Act opened last week to a flurry of rumours that Academician Andrei Sakharov and his wife, Elena Bonner, have received permission to emigrate.

These rumours, which did little to defuse the procedural hassles that delayed the formal opening of the conference by several hours, so far remain unconfirmed.

Almost simultaneously came the news, confirmed by Dr Efrem Yankelevich, Mrs Bonner's son-in-law, who acts as Dr Sakharov's personal representative in the West, that Dr Sakharov had announced his intention of resigning from the Academy of Sciences of the USSR, with effect from 10 May, if his conditions of exile are not improved, and if Mrs Bonner is not allowed to travel abroad for medical treatment.

Although the Soviet authorities have, on several occasions, tried to pressurize the academy into expelling Dr Sakharov, these efforts have been resisted even by party hard-liners in the academy as liable to set a dangerous precedent. Dr Sakharov's voluntary resignation, however, would clearly not be in the interests of the authorities, in view of the considerable comment it would arouse internationally.

Moreover, Dr Sakharov, who will be 64 on 21 May, is past Soviet pensionable age, and the loss of his academy stipend, which he has still been permitted to draw, would not necessarily put him at risk of a charge of "parasitism" (being without visible means of support). Dr Sakharov has previously been reluctant to leave the Soviet Union, feeling that his presence there provides valuable moral support for the human rights movement and for victims of oppression. Hence in 1975, he did not collect his Nobel peace prize in person for fear that he would not be allowed to return to the Soviet Union. Since he was exiled to Gor'kii in January 1980, he has been effectively prevented from giving any assistance to his distressed fellow-citizens, and in 1983 he accepted an invitation from the Norwegian government to settle in Norway — provided, of course, that he is allowed to leave the Soviet Union.

Prospects for the Sakharovs to emigrate are not, however, promising. According to Dr Yankelevich, Mrs Bonner, who was sentenced to three years' internal exile to Gor'kii in August 1984, was excluded from the amnesty proclaimed in honour of the fortieth anniversary of the end in Europe of the Second World War. Dr Sakharov's own exile, of course, is the result of an administrative decision and, technically speaking, has no legal validity.

Vera Rich

Genetic engineering

RAC stakes its claim

Washington

IN the face of proposals to create a new layer of bureaucracy to oversee genetic engineering, the Recombinant DNA Advisory Committee (RAC) of the National Institutes of Health (NIH) has begun to assert itself with a new vigour. At the meeting of the committee on 2 May, members voiced concern that other agencies moving to assert jurisdiction over recombinant DNA — in particular the Environmental Protection Agency (EPA) — lack the expertise that RAC has accumulated in its 10-year existence and that basic research could suffer as a consequence.

The focus of concern is the lengthy proposal of the Office of Science and Technology Policy (OSTP) for the establishment of a "coordinated framework" for regulating biotechnology (see *Nature* **313**, 85; 1985). Under that proposal, a Biotechnology Science Board, a sort of "super-RAC", would be created to address generic issues and to settle interagency disputes; in addition, each agency that deals with biotechnology (US Department of Agriculture, National Science Foundation, EPA, Food and Drug Administration and NIH) would have its own RAC to provide advice within the agency.

Although most of this proposed bureaucracy would address only applications for marketing or development of commercial products and would not involve any new statutory authority, EPA has indicated its intention to claim some authority over research. The agency has already said that field tests of microbial pesticides produced by genetic engineering come under the Federal Insecticide, Fungicide, and Rodenticide Act (nothing new), and (a definite departure) that the usual 10-acre exemption would not apply. Under interim rules announced by the agency, anyone who wants to field-test a genetically engineered microbial pesticide on a plot of any size must notify EPA; the agency can then demand a formal application for an "Experimental Use Permit".

EPA also intends to view the DNA in novel microbes as "new chemical substances", subject to the notification and safety-testing requirements of the Toxic Substances Control Act (TSCA). Under that act, EPA must be notified 90 days before the manufacture of such a new substance commences; EPA can demand additional data and with cause can restrict or even ban the product.

In a letter from RAC chairman Robert Mitchell to OSTP, the concern of RAC about the proposal was spelled out; RAC members say that EPA and other agencies appear to be reinventing the wheel, raising questions that RAC was able to lay to rest years ago. And there is strong feeling within RAC that all laboratory research at least must remain the business of RAC alone.

In discussion at this month's meeting, members made it clear that a major function of the committee since its inception — in the committee's own view, that is — has been protecting basic research from overregulation, a feat accomplished largely by providing a forum for defusing public concern and heading off demands for regulation *per se* through a demonstration of cautious self-regulation.

Although EPA's TSCA proposal raises the possibility of EPA's regulating even the laboratory research phase of certain commercial biotechnology products, RAC in fact faces little challenge to its claim to having exclusive oversight over laboratory experiments. The major grey area at this point is environmental testing. The RAC staff, still staggering under the paperwork and legal burdens of the Lindow-Panopoulos proposal for field-testing genetically altered ice-nucleating bacteria, would like to turn it all over to EPA. A proposal by the staff, on which RAC decided to defer action at the last meeting, would allow RAC at its discretion to accept the review of a proposal by other agencies as meeting RAC's requirements. The partial victory by anti-genetic-engineering activist Jeremy Rifkin in the Court of Appeals (see *Nature* 7 March, p.6) has opened the way for continual court challenges of the adequacy of RAC's approval of Lindow's experiment and other environmental-release experiments, another headache that the staff would as soon avoid.

At least a part of the RAC membership, however, is less ready to concede that jurisdiction to EPA. RAC has adopted an informal document to guide those submitting proposals for environmental-release experiments (*Points to Consider for Submissions Involving Testing in the Environment of Microorganisms Derived by Recombinant DNA Techniques*); it was noted at the recent meeting that RAC enjoys the flexibility easily to amend this document with experience; the regulatory agencies face a much more ponderous process.

US education

More engineers needed

Washington

THE chronic shortage of engineering faculty at US universities has arisen largely because engineering professors are paid $10-12,000 a year less than their counterparts in industry, according to a $900,000 study of engineering education* published last week by the National Research Council (NRC). And although the number of engineering PhDs awarded each year will increase over the next few years to 4,000 in 1988 (from 2,800 in 1983), this will still not be enough to meet the increased demand from industry and academic institutions.

According to NRC, 8.5 per cent of engineering faculty positions are unfilled, and 6,700 new appointments would have to be made to restore student/staff ratios to the levels common in the mid-1970s. The situation is unlikely to improve greatly unless a university career is made more attractive for talented researchers. An associate professor in his 30s, for example, will typically earn less than $38,000 a year.

NRC calculates that as many as 30 per cent of all US engineers work for the government either directly or indirectly, and uses this statistic to argue that both government and industry would be working for their own benefit in making advanced engineering studies more attractive. Legislation should be introduced that would "facilitate" gifts of laboratory equipment to engineering colleges. And the federal government should be prepared to match dollar for dollar funds raised for new buildings.

NRC makes surprisingly little attempt to analyse future demands for different engineering skills, but does predict that the number of engineers needed will increase. The lack of hard numbers is blamed on the poor quality of existing databases, and NRC asks in passing that the National Science Foundation (NSF) should do something about it. One somewhat sensitive problem, however, is that more than 40 per cent of graduate students studying engineering in the United States are foreigners on temporary visas, many of whom will return to their own countries after graduating. NRC wants to see more US citizens in the pool.

The NRC study is critical of the way that most federal support for engineering is channelled into a relatively small group of "first tier" colleges specializing in graduate education. More than half of engineering graduates with bachelor of science degrees graduate from the disadvantaged second tier colleges, however.

NRC is laconic when it comes to what exactly should be taught, however. The study concludes, on the basis of verbal arguments, that it might be advantageous to delay specialization in some arcane fields in order to improve management and communications skills, apparently often lacking in engineering graduates; again, NSF is asked to experiment with novel courses.

The NRC study was supported by NSF, the National Aeronautics and Space Administration, the armed forces and industrial corporations.

Star wars

Franco-German accord?

THE disagreement at last month's summit meeting between France and West Germany over participation in the US star wars programme seems to be blowing over. President François Mitterrand seems to have offended Chancellor Helmut Kohl at the Bonn meeting by saying that France would not take part, and seems himself to have taken offence at West Germany's willingness, which was taken as a sign of disinterest in the alternative French proposal of a European programme of high-technology research, called Eureka. It is now expected that these differences will melt away when Mitterrand visits Bonn later in the month, but meanwhile it has come to light that two major French companies are planning to go ahead with star wars research in any case. So what exactly did Mitterrand's gesture mean?

M. Pierre Aigrain, research director of Thomson-CSF, one of the two French companies suspected of star wars complicity, said last week that he "didn't know". And others, pointing to the electronics and armaments company's continuing heavy losses, suggested that if Thomson-CSF could (quietly) find a slice of the $26,000 million star wars budget, nobody in France was going to complain too much.

Aigrain, himself an ex-minister (of research), agrees that, on the whole, Mitterrand is right to be wary of arrangements in which Europe would act merely as subcontractor to the United States. But would Thomson-CSF itself consider such deals? "That's something we would look at on a case by case basis", said Aigrain. His company is among the world leaders in higher power vacuum-tube technology. "If we were asked to develop a special high power tube, I don't know whether we'd say no. I think probably we'd consider it if the funding's all right and so on. A company will always react by thinking about its own profit." When it comes to research funding from abroad, however, a company would need government approval.

Aigrain considers, as does the French government, that in the Strategic Defense Initiative (SDI or star wars) programme, the United States "is at least as much looking for a way of advancing technology as it is in developing an active weapons system". In Europe, this technology should be developed by European cooperation, Aigrain believes, thus defending President Mitterrand's proposal of a major civil programme, Eureka, to match those aspects of SDI capable of civil application.

"The big problem is that until now, with the exception of the European programme of research in information technology (ESPRIT), Europe has been spending extremely little on joint technology programmes". Even ESPRIT is costing only one-fiftieth of the SDI budget. Thus Mitterrand's Eureka "is a way to say we've no option but to spend a lot more money on advanced technology. As far as this is concerned I can only say I'm in favour of it", said Aigrain.

The money should not come from extra taxes, but from rechannelling existing, poorly-spent sums. In telecommunications systems, Europe spends more on research and development than the United States and Japan put together, according to Aigrain. But much of the spending is duplicated and "rather ineffective".

The problem with SDI for Europe, says Aigrain, is that the programme has been put under the military. "It's true in every country in the world that the defence establishment is usually the most efficient user of technological advance. One may not like it but it's true. The problem in Europe is that we don't have a military establishment at European level. but I don't think we should have this until we have a much greater level of political unity."

The most important spin-off from SDI will be in communications and systems, Aigrain believes. "It's obvious — people are always speaking of the basic weapons part of SDI but a much bigger challenge is the automatic collection of information, processing the data, making an intelligent system, says Aigrain. He believes the development and civilianization of such technology may be the biggest effect of SDI.

Robert Walgate

Royal Society

All change ahead in London

THE Royal Society of London seems to be well launched on a period of organizational change, with a new management structure, new people in top posts and with ambitions to exert more influence on public policy. The immediate occasion for the change is the retirement of Dr R.W.J. Keay from the post of executive secretary of the society with effect from 20 May.

Keay is to be succeeded by Dr Peter T. Warren, deputy secretary since 1977. The society has taken this as an opportunity to equip itself with a middle management structure. The post of deputy secretary has been abolished, but instead there will be three officials responsible for national, international and financial matters.

Sir George Porter.

Mr Peter Cooper, a member of the society's staff for the past ten years, will be the assistant secretary responsible for national affairs, Mr S.J. Cox (now at the British Embassy in Washington) will look after international affairs while Mr N.B. Parfitt, now the society's finance officer, will be in charge of finance and administration. One of the officers of the society says that the need for the new structure has been appreciated for some time, but that the change has been delayed by lack of funds.

Among the new directions in which the society is embarking is that of providing a more systematic commentary on the condition of British science than has been possible by means of the *ad hoc* studies carried out by voluntary committees, which have nevertheless been a growing part of the society's work in the past five years.

The plan now is to set up a small unit, comprising perhaps three professional people, to compile a database describing the pattern of British academic research and eventually to produce analytical papers which, it is hoped, will guide the often acrimonious public debate about the scale and mechanisms of research support in Britain. To ensure the independence of this unit, whose acting head is Dr Peter Collins, the Royal Society plans to meet the costs out of its own funds, not from those supplied by the central government.

Meanwhile, the Royal Society is also preparing for one of its quinquennial changes at the top. Sir Andrew Huxley, president of the Royal Society for the past five years, will retire on 30 November and be succeeded by Sir George Porter, director of the Royal Institution since 1966, who shared a Nobel Prize in 1967 for his work on the use of lasers in the study of rapid chemical reactions. Porter plans to retire from the Royal Institution, but a date has not yet been fixed.

The effects of this change are, as always, unknowable. Sir Andrew Huxley, thought before his election as president to have been shy of public controversy, has been outspoken on a variety of issues, ranging from the Soviet treatment of scientists and the rights and wrongs of cladistics to the British government's regard for basic science. Dogged determination has been the watchword in the past five years.

Porter is more mercurial than Huxley, and has earned a reputation as a popularizer by means of his work with television, which fits in with some of the society's ambitions to improve the public presentation of science. □

Japanese environment

Rediscovery of pollution

Tokyo

PUBLIC outcry over pollution has almost vanished in Japan as the once notorious Tokyo smog becomes just a memory of the 1970s: the feeling is that the really big problems have been beaten.

The White Paper (policy statement) just released from the Environment Agency thus comes as something of a shock, detailing a host of new and more insidious problems.

There is no doubt that major battles have been won in the control of air pollution. Ten years ago, photochemical smog warnings were issued on close to 300 days of the year and some 5,000 victims a year were being registered in Tokyo alone. In 1965, things got so bad in Yokkaichi, a refinery port close to Nagoya, that all primary school children in the most polluted parts of town were issued with special face masks — not that they appeared to be effective. Now, nitrogen dioxide levels in the air are steadily declining in most parts of the country, despite increased traffic, and smog alerts are down to some 130 days a year.

Where new problems are arising is in the pollution of rivers and lakes and in the mass movement of population to new satellite cities with an infrastructure ill-prepared to receive them. Japan's largest lake, 674 square kilometre Lake Biwa, provides a classic example. The population of Shiga prefecture, in which the lake is located, is growing very rapidly as people move out of the nearby Osaka and Kyoto conurbations in search of a better environment and industries are relocated where land is cheaper.

The resulting effluent pouring into the lake, coupled with acid rain from the huge industrial areas nearby, is now rapidly turning it into a graveyard. The shallow southern half of the lake is in a state of almost total eutrophication, and the northern half is plagued by "red tides" — freshwater algal blooms. Attempts to cut the input of phosphates, by banning sale and use of phosphate detergents, for example, began in 1980 but came too late; it is unlikely that the lake water will show major improvement this century.

Similar problems are seen in many other lakes and rivers, and pollution is spreading into underground waters. Analysis of water in wells shows that some sites are contaminated by carcinogenic organo-chloro compounds at 600 times the levels recognized as safe by the World Health Organization, a serious problem given that 30 per cent of Japan's drinking water comes from underground sources and that the sources of pollution are virtually untraceable with present understanding of underground water flow.

All this highlights the way in which movement of population from the countryside and giant cities into suburban satellite cities, accompanied by an increasing reliance on automobiles, has not been accompanied by adequate attention to sewerage and water supplies. "A glut of Walkmans and a shortage of sewers" was how experts from the Organisation for Economic Cooperation and Development recently summed up Japan's emphasis on private rather than public expenditure. Noise, traffic jams and garbage disposal problems are also becoming more severe in the new cities as they inherit the crises of the larger cities, and with Japan's urban population expected to reach 70 per cent of the total by the end of the century, there is little hope of a let-up in the pressure. But creating new urban infrastructures, or the greater dispersal of population and industry that the white paper calls for, cannot be achieved without massive expenditure that the government seems unwilling to make.

To cope with deterioration of lake and marshland, the Environment Agency has introduced legal limits on the levels of phosphorus and nitrogen effluent that can be discharged by industry. Japan is the first nation to attempt to control both factors. Initially stringent limits were, however, reduced after opposition by the Ministry of International Trade and Industry (MITI), highlighting the Environment Agency's own lack of power. Although the agency was originally intended as a single comprehensive pollution control body, when it was set up in 1971 it found that ministries with regulatory powers over pollution, particularly MITI, were unwilling to relinquish them. The result is that the agency is a watchdog without teeth: it can plan and coordinate policies but is not responsible for enforcing them, except in the case of wildlife protection.

In this area, the Environment Agency has just shown a willingness to respond to international concern by setting up a new "Headquarters for Wildlife Protection Measures". Severe criticism of Japan from abroad, reinforced by the visit of Prince Philip, Duke of Edinburgh, in his capacity as president of the World Wildlife Fund (see *Nature* **311**, 698; 1984), for failing to obey the Washington Convention prohibiting the import of endangered species, was the chief stimulus to the establishment of the new office. The number of customs houses through which wildlife can be imported has been reduced to nine and officials are given training in spotting illegal imports.

The white paper itself, however, pays scant attention to international issues. Although it charts the destruction of tropical rain forest in South-East Asia — destruction in which Japanese logging companies and Japan's voracious demand for timber have played a large part — it does not call for any action other than membership of standard international environmental organizations. **Alun Anderson**

French universities

New watchdog barks well

Paris

UNDER a dozen glittering candelabra that must each weigh a ton, beneath the frescoed ceilings of the Elysée Palace and surrounded by much of the academic élite of France, President François Mitterrand last Friday gave his full dignity to the latest effort to reform the French university system, the establishment of the Comité National d'Evaluation des Universités, or CNEU.

The purpose was serious, and the guests were hopeful, especially the director-general for the universities at the ministry of education, M. Jean-Jacques Payan, whose cheerful face has been proclaiming lately that he thinks his job now done. The 75 French universities, many created shortly after the 1968 student revolt, and mostly egalitarian and left-wing in spirit, have been opened up to once-hated industry and now, through CNEU, to competition among themselves.

The committee "responds to an evident need" said President Mitterrand on Friday. "It signifies for our country an innovation of major importance." It represents the increasing autonomy of the French universities (sweet words to the relatively powerless university presidents) whose counterpart is "the objective evaluation of their strengths and weaknesses" (rather more bitter words for the feebler institutions).

CNEU will be "entirely free" to make its own judgements and will report each year to the President. M. Mitterrand said, "I expect reports to have concrete effects" on the decisions of the French administration. (CNEU will not directly control and divide funds as does, say, the British University Grants Committee.)

The French universities, described by M. Henri Tézenas du Montcel, who resigned as president of the University of Paris (Dauphine) to write a critical book on his *alma maters*, as those "foggy and smoky" places, are now required, said M. Mitterrand, "to be more transparent and to develop the best among them".

The universities must obey three principles, he said: autonomy, which the President expanded to mean obedience to the recently-introduced system of research contracts agreed between the ministry of education and each university, assessed *a posteriori*; "emulation", a soft word for "competition" in which each university must attempt to emulate the best elsewhere; and quality, "the condition of success in scientific competition... and world technology, which greatly depends on the success of our universities and scientists". On this success the French people depend. And the President depends on CNEU to help increase the quality of the univer-

sities "and therefore the chances for France".

M. Laurent Schwartz, like M. Tézenas du Montcel an old critic of the French universities, is presiding over CNEU, but had raised himself from his sick-bed to deliver his opening address last Friday. He pronounced himself "sensible to the solemnity" that the French President was giving to the installation of his committee, and promised to make of CNEU "an instrument fundamental to the success of the French universities".

According to Schwartz, French universities have been subjected until now to little real objective evaluation, either internally like the US universities, or externally, like the British. In France, there has been only piecemeal evaluation by the research councils, or by the national university promotions committee (the Conseil Scientifique des Universités). CNEU would introduce global evaluation, something "much more ambitious".

"The question is to make known to each establishment, to the minister of education and to public opinion how the universities are doing branch by branch and globally." The better a university does in its evaluation, the more autonomous it should expect to become. CNEU would not distribute money directly, as that might result, in the long term, in "equipartition".

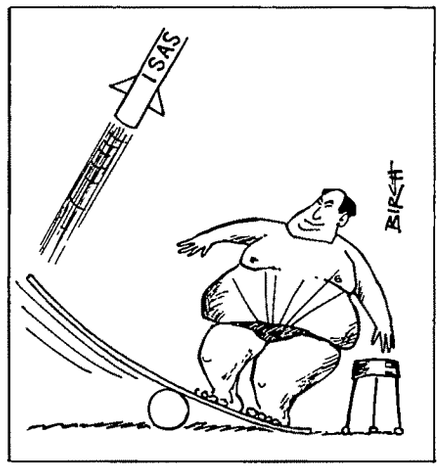
The regulations defining CNEU give it an "entirely new" freedom of movement, said Schwartz. It will have "absolute independence". Many organizations in France are governed by strict rules penned out in minute detail. But "the decree that establishes our committee leaves us on the contrary complete freedom to evaluate as we wish". If only, dreamed Schwartz, this atmosphere of confidence and liberty could extend to other organizations — such as the universities themselves.

"We must combat taboos and corporatism", said Schwartz. "We must understand and make understood: that demands courage and objectivity. We will force ourselves to have them. The grandeur of our task is impressive but is also fascinating."

The 15 members of CNEU will not carry out all the evaluations, but will appoint outside independent experts, said Schwartz. CNEU will use international experts as much as possible "as is done throughout the world". CNEU will not evaluate individuals, but will work at the level of groups and above. It will consider both research and teaching together, "for to separate research and teaching would kill both".

"CNEU will not behave like a policeman" said Schwartz. "Evaluation is totally contrary to Napoleonic control. We shall not be checking that the universities follow all the rules. On the contrary, we shall see if the universities can innovate, if they can launch audacious projects: we shall support initiative and not conformism or retreat."

Robert Walgate



Japan in space

David keeps Goliath guessing

Tokyo

THERE seems no limit to the ambitions of Japan's Institute of Space and Astronautical Science (ISAS), the tiny academic cousin of the government-run giant National Space Development Agency (NASDA). Despite a shoestring budget and home-grown solid-fuel rocket technology, the agency is determined that Japan should be the third country to send a satellite to the Moon.

ISAS has just revealed that it is drafting a detailed programme to launch Japan's first Moon observation satellite in fiscal year 1989. Under the plan, a satellite will be placed in Earth orbit and, after a day for accurate orbital alignment, will be blasted off for the Moon by a "kick motor". On its first pass, the satellite will be slung past the lunar surface at an altitude of about 6,000 km, one month later reaching an apogee of well over 1 million

km. Thereafter, it will be catapulted back towards the Earth-Moon system and, after a second "near miss" of the Moon, will enter a highly eccentric Earth orbit stretching across the Moon's path. Two months and four Earth orbits later, the satellite will then whip off on another two-month loop around the Moon, or so the theory goes, but according to ISAS's "gunnery lieutenant" Hiroki Matsuo, professor of orbital dynamics, much more detailed calculations will be required before he can predict exactly where Japan's first Moon shot will end up.

Given ISAS's resources, it is a wonder that this organization can even contemplate a lunar mission. Japan is unique in having two space organizations, each equipped with its own satellites, rockets and launch sites. The larger NASDA, affiliated to the Science and Technology Agency, is in charge of the development of applications satellites and their launch vehicles, while ISAS, affiliated to the Ministry of Education, Culture and Science and operating on a fraction of NASDA's budget, carries out research and development of scientific satellites and launch vehicles. NASDA uses liquid fuel rocket technology developed almost entirely under US licence but ISAS has its own "home-made" solid fuel launchers.

In the 1960s, when ISAS was part of Tokyo University rather than a national institute, the Japanese government asked the institute to limit the size of its rockets, to avoid competition with NASDA and to prevent the academic organization getting too big for its boots or so it said. By the early 1970s, ISAS had already reached the 1.41-m limit on the tail diameter of its rockets, since when its MU-series rockets have been getting taller and taller but no wider, at least at the base. With the Moon shot, however, ISAS is reaching the limits of ingenuity in what it can do with its present launchers.

To kick the lunar probe out of Earth orbit and off to the Moon, ISAS plans to add a 500-kg fourth stage to the MU-3SII used in the successful launching of the Halley's comet test satellite, *Sakigake* (see *Nature* 17 January, p.175). Add to this the 170-180 kg weight of the satellite and the payload capabilities of MU-3SII will be stretched to the full, whence ISAS's cunning plan makes gravity do most of the work. Launch dates and total budgets for the programme have not yet been agreed but Y160 million ($0.6 million) has been approved for systems design in the current fiscal year.

Unlike previous programmes, the lunar programme, codenamed MUSES (MU Space Engineering Satellite), is aimed largely at engineering studies of control of the speed and orbit of the satellite and, according to Professor Matsuo, no scientific instruments will be carried on the first satellite, MUSES-A. However, a possible successor, MUSES-B, may carry a scientific package to be dropped to the lunar surface.

But the big question in the minds of the institute's members is what more can be done with present launch facilities. Among the projects under consideration are a solar physics project for observations of solar flares that would, ideally, be carried out at the next solar maximum in 1991, but which would clash with a plan, in conjunction with the US National Aeronautics and Space Administration, to launch a satellite from the space shuttle which would follow a similar profile to MUSES-A. So the solar physics project will probably be scheduled for 1992.

Also under consideration is a project to examine diffuse X rays following on the successful series of X-ray satellites, while the institute also has more grandiose ambitions to send satellites to the planets which would be beyond the capabilities of MU-3SII. Using NASDA launchers would help, but NASDA has its hands full while ISAS cherishes its independence.

David Swinbanks

French research

End to growth in sight?

MORE is not enough for the French national research council, CNRS (Centre National de la Recherche Scientifique). Despite a real increase in its spending since 1981 of over 35 per cent, a figure only to be dreamed of on the other side of the English Channel, CNRS is pressing the ministry of research for a further increase this year. And that increase should be double last year's, at least in support for laboratory equipment and materials, and approach a real 10-12 per cent annually for the next three years, CNRS director-general Pierre Papon is claiming.

But research minister Hubert Curien, whose new three-year plan for the future of French science is now before the prime minister Laurent Fabius, has warned CNRS that it may have to be content with what it has. And with the French government facing a possible trade deficit this year as opposed to a planned surplus, and Fabius refusing to win votes in next year's parliamentary elections with a spending spree, Curien may well be right.

Papon, however, says this may mean cuts in the CNRS 5-7 year plan announced recently (see *Nature* 2 May, p.5), in which 20 research areas were selected for special effort. That plan itself required some hard choices, claims Papon, and to develop it requires the re-equipment of some laboratories, particularly in minicomputing and other "middleweight" expenditure.

But has the period of plenty at CNRS, which amounted to an average real increase of 5.5 per cent a year in total budget for the five years 1981-85, not left the organization sitting pretty, with cash to spare? Not according to some outside observers, who judge that President Mitterrand's policy of "solving the economic crisis" by spending on science and technology has left basic science, the fields mostly supported by CNRS, protected from cuts, but not truly expanded. The 5.5 per cent "real" increase against French domestic inflation has been swallowed up by a falling French franc against harder currencies in which most scientific equipment and materials must be bought (typically dollars, marks and Swiss francs).

Nevertheless, CNRS is attempting to share equipment costs, and technicians, by creating "federated institutes" around well-instrumented laboratories, linking three to five existing groups around genuine joint research objectives. This will have the double advantage of reducing costs and of unifying an often fragmented French research effort. But still "money is the big problem" Papon says, thus shedding a disturbing light on those research councils elsewhere whose budgets have remained fixed if not falling.

Innovations other than more money that CNRS would like to see in the new plan, which should go before parliament in July, include an increase in the number of studentships for people studying for one of the new PhD degrees, more incentives to mobility of scientists, and the establishment of more CNRS-linked laboratories in the *grandes écoles*, the élite engineering schools which tap the best talent emerging from French secondary education.

Although these schools produce some 12,000 engineers a year, only 5-7 per cent go on to do a PhD (or the previous equivalent, "third cycle" diplomas), according to CNRS figures. This lack of scientific training is a "real handicap" for French industry (of which the graduates of the *grandes écoles* often become leaders), according to Papon.

Robert Walgate

CNRS spending

Over the period 1981-95 inclusive, the spending of the French CNRS (which supports 10,000 of its own scientists, 25,000 engineers and technicians, and many more scientists by means of grants at universities) is estimated to have increased (in real terms) at average annual rates of:

- **2.9 per cent in nuclear and particle physics (excluding international subscriptions).**
- **5.4 per cent in other basic physics and mathematics.**
- **8.4 per cent in physics for engineering.**
- **5.1 per cent in chemistry.**
- **4.1 per cent in Earth sciences and astronomy.**
- **6.0 per cent in life sciences.**
- **6.0 per cent in social science and humanities.**
- **14.5 per cent in interdisciplinary programmes.** □

Charitable foundations

Wellcome Trust plans asset sale

THE British medical charity the Wellcome Trust, whose only substantial asset consists of 100 per cent of the shares in the Wellcome Foundation, the successful pharmaceutical manufacturer, is planning to increase its income and diversify the source from which money flows by disposing of a fifth of its holding in the company.

The immediate attraction of the proposed share sale is that the trust could expect to realize a substantial sum of money from the sale which, invested in high-yielding securities, might even double its income, which is estimated to amount to £23 million during the present year. During 1984, the Wellcome Foundation earned a profit (after tax) of £48.6 million on a turnover of £806 million.

The share prices of comparable companies, such as Glaxo, are at present not very different from 20 times the net earnings per share, which would value the Wellcome Foundation at something like £1,000 million.

A statement put out by the trust earlier this week emphasizes, however, that diversification is also a large part of the trustees' motives in disposing of part of their shareholding. The trust says that the trustees have "for some time been concerned about the wisdom of having all their eggs in one basket". But the statement also says that after the disposal of 20 per cent of the shares, the trust will not sell further shares for at least two years, and that it will not allow its shareholding to fall below 50 per cent.

The chances are that the new arrangement will also benefit the foundation, whose attempts to behave as a thoroughly commercial organization have always been cramped by the relationship with the trust. The relationship has, among other things, prevented the company from rewarding its senior employees by means of share options and from growing more quickly by the acquisition of other companies in return for its own stock. The second constraint will remain so long as the trust retains a controlling interest.

The relationship between the trust (which is technically a charitable foundation) and the foundation (which is a commercial company) derives from the will of Sir Henry Wellcome, who died in 1936 leaving to the trust which he created the sole ownership of the company, originally Burroughs Wellcome Ltd. The company was renamed the Wellcome Foundation in 1926.

Over the years the relationship between the trust and the foundation has been curiously ambivalent. Each has been jealous of its independence from the other, with the company repeatedly in difficulties in explaining to its dependent charity why its annual share of the commercial profit has to be substantially less than 100 per cent. (In 1984, the trust received £17 million of the total profit of £48 million, most of this by way of payments under deeds of covenant allowing the company to economize in tax payments.)

Even so, the trust is now the largest of the private foundations in the United Kingdom.

In a quite separate development, Sir John Vane, research director at the Wellcome Foundation for the past eleven years, announced last week that he is to leave the company so as to devote himself to his scientific interests. Vane, who was awarded the Nobel prize for his account of the mechanism of action of aspirin, said last week that he has no immediate plan to do something else. □

UK agricultural research

Penury brings radical reappraisal

ADVERSITY (mostly financial) has persuaded the most threatened of the British research councils, the Agricultural and Food Research Council (AFRC), to canvass a radical plan of reorganization. One proposal would reduce the number of separate institutes from about twenty (with seven separate Scottish research institutes) to perhaps half that number.

It is also proposed that there should be a management board for agricultural research to which would belong research council officials and a representative of the Department of Agriculture and Fisheries, Scotland, as well as the "ten or fewer" institute directors.

The discussion document, *A long-term view*, says that the number of research institutes would be reduced "by successive amalgamation and restructuring", and that wherever possible institutes will be sited on or near a university campus. Under such a regime, institute directors would have a greater degree of independence in the direction of management of the research for which they were responsible. The document suggests that it should be possible, within such a framework, to give research groups more flexibility, by specifying "the questions to be answered rather than the areas of science to be studied".

Part of the council's management problem is that many of the research institutes for which it is the chief source of financial support are not formally directly under its control, but are historically independently constituted. The Rothamsted Experimental Station is one of these. Thus, in the discussion document, AFRC suggests that people whose salaries it pays should in future be its own employees, which would entail both a change of status and, for some people, a greater degree of insecurity. No doubt the council would benefit through the greater freedom it would have to move people from one place to another.

The discussion document says little about its immediate origin, the proposed reduction of funds for research commissioned by the Ministry of Agriculture, Fisheries and Food of £10 million in the current financial year and twice as much during 1986-87. The question is to be considered by the priorities board for research in agriculture at a meeting later in the summer, but it appears that there is very little prospect of relief from the Treasury edict that these substantial sums of money should be lopped from what has become, in effect, part of the council's budget.

Among the other proposals put forward in the discussion document is the suggestion that the need to avoid duplication of research effort within Europe may make it necessary for the council to withdraw from some fields of research.

But the council is plainly also hoping that it would win research support from elsewhere for some of the research that it carries out at present. The document also repeats the council's expressed intention, during the past several years, of increasing its income from research contracts with private industry as well as from other government departments than those responsible for agriculture.

On people, the council promises to consult trades unions on the reorganization outlined in the document, and says that it acknowledges the need that creative scientists should have a secure environment in which to work. But it also says that it needs to plan for change, for which reason it will continue to recruit many of its staff on short-term contracts.

Flying a more adventurous kite, the council says that part of its case for continued existence is that AFRC is responsible for the "largest non-medical biological research capability" in Britain, which will be widely taken as a reference to the fondness of Sir Ralph Riley, the recently-retired secretary of the council, for the creation of a new research council with responsibility for basic biological research, medical and non-medical.

Comments on the discussion paper are invited by 15 July. □

Tumour necrosis factor

Drug agency jumps TNF gun

Washington

IN an unusual move, the US Food and Drug Administration (FDA) has allowed human tumour necrosis factor (TNF) produced by recombinant DNA technology to be given to a cancer patient. FDA had previously maintained that there are insufficient animal data on the effects of TNF to approve clinical trials, but it has now allowed Dr Herbert Oettgen of Memorial Sloan-Kettering Cancer Center in New York to treat a gravely ill patient with TNF manufactured by the Asahi Chemical Industry company of Japan.

In the normal course of events, FDA grants a so-called Investigational New Drug exemption — permission to enter clinical trials of a putative therapy — only when there are sufficient data to provide a reasonable expectation that the therapy will be safe and effective. FDA allowed a compassionate exemption for the Sloan-Kettering patient on condition that Sloan-Kettering's institutional review board accepts full responsibility for the case, since FDA had no prior information on the TNF used, and the data submitted with the compassionate exemption request covered only basic safety requirements such as pyrogenicity and sterility.

FDA itself appears to be confused about the exemption. Even after granting Sloan-Kettering permission to use TNF on its patient, FDA officials were insisting that the substance was not being used on patients in the United States.

The Sloan-Kettering patient is said to be a member of the staff of the institution. The request to FDA for a compassionate exemption was approved unanimously by over 30 members of Sloan-Kettering's institutional review board on 9 April; according to Dr John Lewis, chairman of the board, FDA was provided with a treatment protocol, a detailed clinical assessment of the patient's condition and "voluminous" information about TNF.

Dr Doris Hutchison, head of the institute's investigational drug committee, said that FDA's bureau of biologics had been "very co-operative" in dealing with the request.

FDA not infrequently grants Investigational New Drug exemptions on compassionate grounds when the relevant animal data have been submitted for FDA's consideration but are held up in the bureaucratic pipeline. Patients with acquired immune deficiency syndrome (AIDS) have been treated under compassionate exemptions with drugs approved for other conditions, for example. Compassionate exemptions have also been granted for trials on seriously ill patients who fall just outside the age range specified in the protocol for a clinical trial. It is, however, less common for FDA to approve what amounts to a clinical experiment when the data are as fragmentary as they are for recombinant human TNF. Some authorities on medical ethics speculate that FDA might feel justified in making an exception if the patient concerned has a sophisticated understanding of the risks and benefits of the treatment.

Dr Lloyd Olds, associate director of scientific development at Sloan-Kettering, is one of the original researchers on TNF, first produced from mouse serum. Dr Olds is being supplied with genetically engineered human TNF for research purposes by Genentech Inc.

Although this material is being used only for animal and *in vitro* studies, according to Genentech, Asahi's TNF is undergoing clinical trials in Japan. After the publication of scientific reports detailing the cloning and expression of the human TNF gene (*Nature* **312**, 721 and 724; 1984 and **313**, 803; 1985), researchers at Genentech and Asahi were deluged with enquiries from anxious cancer sufferers and their families about where TNF could be obtained.

It is still unclear how soon organized clinical trials of TNF will start in the United States, or whether the Sloan Kettering case will serve as a precedent for future compassionate exemptions in similar cases.

Tim Beardsley

Halley's comet in ancient times

SIR — In his comment on the Babylonian observations of Halley's comet[1], C.B.F. Walker states that in Mesopotamia "almost all the early texts are concerned with astrology rather than astronomy"[2]. Walker continues by noting that the earliest astronomical observations known to Ptolemy in *circa* AD 150 dated "from the time of the Babylonian king Nabonassar (747–734 BC)". Both these points deserve comment.

First, although doubts have been expressed as to the link between astrology and astronomy in Babylonian times (for example, ref. 3), there is no firm evidence that the powerful temple priests of Mesopotamia made any distinction between what we call by the separate names of "astrology" and "astronomy": facility in expounding the former necessitated skill in understanding the latter.

Second, Sawyer and Stephenson showed in 1970 (a hypothesis confirmed by Muller and Stephenson in 1975)[4] that what was in all likelihood a total solar eclipse was observed during daytime at Ugarit on 3 May 1375 BC. It seems fair to assume (although the details were not known to Ptolemy in AD 150 and are still not known fully to us now) that astronomical observations took place in and around Mesopotamia for a considerable period of time before 747 BC.

Embryo research

SIR — Professor J.A. Davis (*Nature* 25 April, p.666) wonders whether a "legally or morally valid distinction" can be made between negatively interfering to stop a natural process, for example by procuring the abortion of a fetus *in utero*, and simply refraining from "positive intervention required for its survival", by not putting an egg fertilized *in vitro* into a woman, without which it must inevitably die.

But there is at any rate a *legal* difference between intentionally killing someone and doing nothing to save him. You are under no legal obligation to rescue a drowning man, and if you feel morally obliged to jump in to help him that is a matter for your own conscience, and no concern of the law. But to push him in deliberately is certainly a criminal offence, and probably murder if he drowns.

Professor Davis rightly understands that the argument in my last letter (*Nature* 14 March, p.126) could not be used to justify aborting an embryo that had already started on its normal development *in utero*, but that it might allow experimentation with embryos generated *in vitro* which, undoubtedly human as they are, cannot of themselves realize their potential for further development without some positive act of intervention from outside.

The Warnock Committee (*Report*, para. 11.22) proposed a limit of 14 days for keeping an embryo alive *in vitro* (otherwise than frozen), whether or not is was used for experimental work, and nobody seems to have suggested that this should be much extended. But it should be noted that experiments with living fetuses that have been legally aborted before the age of viability, that is to say up to something over 20 weeks gestation age, are not prohibited under English law. These are by definition doomed to die but they can be kept alive for at least several hours, and considerable publicity was given some years ago to attempts at Cambridge to develop an artificial placenta, using a human fetus which from press photographs appeared to be of 16–18 weeks gestation age. Although the Warnock Report (p.64) has suggested that the law ought to be reconsidered in this respect, such work is at present still quite legal, even if it is not for the squeamish.

C.B. GOODHART

Downing Street,
Cambridge CB2 3EJ, UK

Artificial hearts

SIR — Your leading article "Hearts in the wrong place" (*Nature* 21 March, p.206) classifies you among the modern legal luddites, glorifying form over substance and accepting the idea that the lawyer-regulators know best, regardless of the consequences of their actions.

You admit that Dr Copeland's patient would clearly have died without the use of the artificial heart. In the light of this, neither the patient nor the patient's family was harmed by the heart's insertion and important information was obtained which may well allow the effective use of such hearts or improved models in the future.

There was also the possibility, albeit remote, that the artificial heart might have preserved the patient's life for a long enough time to allow for a successful implantation of a new human heart.

Thus the only potential results of the use of the heart were beneficial, even your editorial writer being unable to discover anyone who had been harmed. The use of available technology in such situations should be encouraged and not barred. In view of the admitted benefits and lack of harm to anyone, Dr Copeland deserves commendation not condemnation.

Value-free science

SIR — Mark Diesendorf (*Nature* 10 January, p.92) questions the notion of value-free science, which I discuss in my letter of 27 September 1984 (p.294). Unfortunately, his comments suffer from the very confusion of categories that I tried to clarify. Since this error has marred much of the discussion of the subject, and since my explanation was excessively brief, it seems worthwhile to consider further what we mean by "science" and by "value-free" or "objective".

The word "science" is ordinarily used to refer to three things: a methodology, a resulting body of knowledge and the ensemble of activities of those who professionally use that methodology. The methodology has evolved a set of canons, and a social framework, designed to ensure maximal objectivity and reliability of the resulting knowledge. On the other hand, the activities of scientists are indeed filled with subjective value judgments: by the individual (what problem to work on, how to approach it, how to present the results), and also by social organizations (what to support, what to accept for publication, how to translate scientific knowledge into technological practice). But despite this subjective element, if the science is honest the practitioner must try to make its *content* — the data and the logical inferences drawn from them — as objective as is humanly possible. He may not succeed perfectly, but at least he should not deliberately inject ideological or other biases.

Diesendorf further calls attention to such presumbably value-laden terms as "fashionable" and "confusion" in my letter. I would suggest that these terms are actually capable of being objectively assessed. But more fundamentally, value-laden terms would not be out of place. For discussions of the nature of science constitute still another category, to be distinguished from the three noted above: they are metascience, presenting philosophical judgments rather than objective knowledge.

Finally, I agree with Diesendorf that problems involving social value judgments should not be treated as though they were purely technological, and his example of planning how to generate electricity fits. But I believe he errs in similarly categorizing the risk of fallout from nuclear weapons. It is a technical question, whose answer then becomes part of the broader question of what to do about these weapons. With the growth of technological innovation we face an increasing number of such questions (for example, the dangers of biotechnology), and we impair our analysis if we do not try to separate their technical from their social aspects.

RADIOIMMUNOASSAY KIT FOR ALPHA-RAT ATRIAL NATRIURETIC POLYPEPTIDE

This kit is designed to measure specifically alpha-rat atrial natriuretic polypeptide (alpha-rANP) and its related peptides by a competitive radioimmunoassay. It is intended for *in vitro* protocols only. The antiserum used for this assay was raised against synthetic alpha-rANP.

This kit contains sufficient reagents for 125 RIA tubes.

Catalog #RIK 9103

Sensitivity:
IC^{50} 8 pgm/tube

Specificity:

Peptide	% Cross Reactivity
alpha-rANP	100
Atriopeptin III	2
Atriopeptin II	1
Atriopeptin I	1
ANF (8-33) (alpha-rANP 3-28)	1
alpha-hANP (Met^{12}-alpha-rANP	0.2
rANF (13-28)	<0.001
rANF (18-28)	0
Somatostatin	0
Oxytocin	0
Arg^8 Vasopressin	0

Contents:

- Triton X-100/water
- RIA buffer (powder)
- Standard alpha-rANP (lyophilized powder)
- Rabbit antiserum specific for alpha-rANP (lyophilized powder)
- ^{125}I alpha-rANP (lyophilized powder)
- Goat anti-rabbit IgG serum (lyophilized powder)
- Normal rabbit serum (lyophilized powder)
- Instructions/flow sheet for the RIA protocol
- Instructions for calculating the results and graph paper for plotting the results.

For every Bio-Medical Application the Right Inverted Microscope from Zeiss

Zeiss offers a large range of inverted microscopes – for routine clinical work, advanced research, and everything in between:
Invertoscope D
ID 02 Invertoscope
ID 02 MT Invertoscope
IM Invertoscope
IM 35 Photo-Invertoscope
ICM 405 Photo-Invertoscope
Photo-Invertoscope Axiomat IDC

Zeiss Inverted Microscopes offer these major advantages:

- examination of specimens of any size
- screening all specimens to the very edges
- comfortable, fatigue-free operation
- unequalled stability
- superior Zeiss optics
- full choice of contrast-enhancement methods
- capabilities of the illumination systems fully utilized
- 35 mm and large-format photomicrography
- compatible with TV and cine cameras, equipment for microscope photometry and image analysis

Zeiss – the trend-setter in optics, precision engineering, electronics

New ways with microscopes

The range of the phenomena usable in the construction of microscopes continues to increase. Neutrons, for example, are now being used in place of photons.

If you have a particle or a field of some kind whose interaction with material objects varies with their constitution, the chances are that you will be able to fashion a microscope from the phenomenon. That truth is nicely illustrated by the versatility of microscopy based on the electromagnetic fields corresponding to optically visible radiation. Contrast between different elements of an object can depend on reflectance, on absorption during transmittance through a thin section, on rotation of the plane of polarization or on variations of refractive index, as in phase-contrast microscopy. The texture of an image is determined by the contrast, but a useful microscope also requires a means of magnification equivalent to the lenses of the familiar microscope. Two new developments this week suggest that people's ingenuity is far from exhausted.

The report by a group of Spanish molecular biologists and Switzerland-based IBM researchers on p. 253 of this issue is an application to a biological problem of a technique of microscopy previously used for the measurement of the surface structure of semiconductor materials and others used in the construction of electronic devices, and which may itself be the only application to microscopy of a strictly quantum phenomenon. Electrons, the textbooks say, will tunnel through a potential barrier if there is a state of identical energy for them then to attain. What is called the scanning tunnelling microscope is for practical purposes a device for arranging that the tip of a fine electrode will physically follow the profile of a surface at a distance of 10 ångströms or less.

In the usual application to the measurement of the profiles of semiconductor surfaces, the voltage between the electrode and the semiconductor is maintained at a value sufficient to promote an electron from the filled valence band to one of the energy states of the largely unfilled conduction band (usually a mere fraction of a volt), but which is less than the work function of the material of which the electrode tip is made, and which then serves as the potential barrier. The electrode tip can then be made to follow the surface profile by means of circuitry, including a piezo-electric crystal, designed to keep the tunnelling current constant, and at a value which may be no more than a few nano-amperes. For all the world, the device is the electronic analogue of the engineering devices for measuring successive profiles of a surface by amplifying electro-mechanically or otherwise the displacements perpendicular to the surface of a small ballbearing that is rolled along in contact with it.

The sensitivity of the quantum tunnelling effect is vividly illustrated by the way in which Baró *et al.* show a series of profiles along a surface of pyrolitic graphite which indicate a step-like structure corresponding to the abrupt termination of a couple of layers of the carbon atoms accounting for less than 7 ångströms of thickness.

Indeed, the resolution of the microscope is reckoned to be of the order of 1 ångström perpendicular to the surface and between 5 and 10 ångströms laterally. Baró *et al.* explain clearly enough how they have been able to correlate the known shapes (from electron microscopy) of bits and pieces of the bacteriophage ϕ29 dried on a graphite surface with the measured tunnel profiles, but their promised account of the mechanism of conduction through these biological molecules could be of great interest in its own right. Their technical achievement, however, is to have made the microscope work in air at ordinary pressure, which should make this type of instrument more versatile even in the measurement of semiconductor surfaces.

The other new development is the first realistic account of a neutron microscope, a goal long advocated by the Soviet physicist I.M. Frank but now realized by a group at the Technical University of Munich and the Laue-Langevin Institute at Grenoble (Herrmann, P. *et al. Phys. Rev. Lett.* **54**, 1969; 1985). This microscope uses "ultra-cold" neutrons from the source at Grenoble, while the microscope itself consists of a pair of mirrors — a large parabolic mirror 20 cm in diameter and a smaller (5 cm) mirror which is convex and spherical.

Ultra-cold neutrons are neutrons moving very slowly, some 6 metres a second in this case. Their interest for would-be neutron microscopists is that they can be reflected from suitable surfaces as if they were photons, which is a simple consequence of the circumstance that, at speeds like this, their wavelength is greater than the internuclear spacing in materials such as nickel-58 (used for coating the "optical" elements in the Munich design).

The snag is that the trajectories of neutrons moving so slowly will be affected by gravity, which is why the two mirrors are arranged in a vertical direction, with the secondary mirror above the primary (and each of them fixed in a horizontal plane with a precision of 10^{-4} radians). Even so, neutrons moving vertically will be decelerated, so that neutrons starting out with slightly different speeds will, left to themselves, come to a focus at different points, which is the equivalent in this field of what those who design optical instruments know as chromatic aberration.

It turns out that the chromatic aberrations of the two mirrors will cancel out only if the neutrons reflected from the parabolic mirror are allowed to reach the peak of their trajectory, at a height of 2 metres or so, and then allowed to fall back onto the secondary mirror, whose reflecting convex surface must therefore point upwards, like the larger primary.

The system has been designed to yield a magnification of 50, with the object placed near the optical focus of the parabolic mirror. The image is formed after reflection from the secondary mirror some 1.5 metres above the primary, whence neutrons are reflected sideways (and downwards, so that they can pick up a little speed) into a neutron detector, which simply counts the numbers arriving. Herrmann *et al.* say that a suitably faceted mirror deflecting neutrons from different parts of the field into different detectors would allow almost instantaneous observations.

So far, they have only the most humdrum observation to report, that of the profile of the neutron intensity across a slit placed in the object plane. The measured resolution of this neutron microscope is 0.1 mm, but that, the authors say, is determined by the counting errors with the low-intensity source of ultra-cold neutrons now available. (Grenoble plans 100 times as much intensity soon.) Aberration with the present arrangement should limit resolution to about 0.02 mm, but preselection of the velocity of the neutrons should allow that to be reduced.

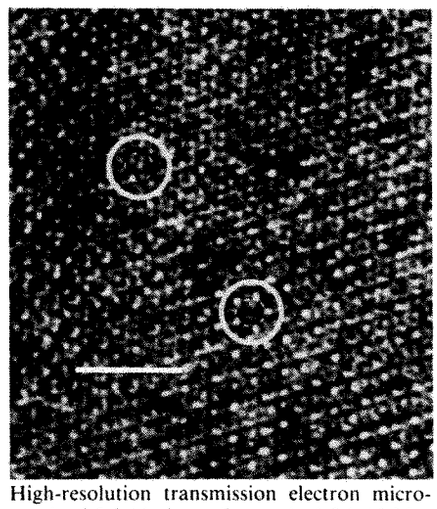
But to what end? The authors' dream is that the reasons and techniques that have made the scattering of thermal neutrons a powerful means of telling the distribution of hydrogen in matter of all kinds can be translated simply into neutron microscopy. But one guesses that a large part of their motivation must be a little like the familiar reason for climbing Everest. Nobody else has made a neutron microscope function at a reasonable magnification, although Frank's Soviet group is well on the way.

John Maddox

Quasi-crystals

Respectable icosahedral symmetry

from Paul A. Heiney



THE structure and properties of icosahedral 'quasi-crystals' were among the topics discussed at the recent meeting of the American Physical Society (Baltimore, 25-29 March, 1985). Quasi-crystals seem to represent a new state of matter in which icosahedral point symmetry is combined with a modified form of translational order. The clue to their structure may lie in the properties of Penrose tilings of a plane (see ref. 1).

Icosahedral ordering was first observed (D. Shechtman, National Bureau of Standards) in rapidly quenched alloys of Al-Fe, Al-Mn, and Al-Cr (ref.2). Dendritic microcrystals up to 2μm in size show the sharp electron diffraction patterns more usually generated by crystals, but with icosahedral rotational symmetry (see figure). Elementary geometry shows that icosahedral symmetry is forbidden for crystalline solids. The usual explanation of electron diffraction peaks which are crystallographically disallowed involves multiple scattering from twinned microcrystallites, but in the present case, the twinning hypothesis appears to be denied by both convergent-beam electron microscopy and dark-field imaging, which are consistent with local icosahedral symmetry on length scales as short as 200Å.

Much of the more recent work has centred on optimizing conditions for the growth of large-grain pure samples in the Al-Mn system (R.J. Shaeffer, National Bureau of Standards and L. Bendersky, Johns Hopkins University). The icosahedral phase is produced either by quenching a stream of molten alloy on a rapidly spinning copper wheel or by sweeping an intense electron beam across the surface of the alloy. If the cooling rate is too great, there are fewer icosahedral grains and they are smaller; if it is too low, ordinary crystals of various Al-Mn compounds are formed. The stability of the icosahedral phase is enhanced by a small amount of Si. An unexpected new 'T' phase, formed at higher Mn concentrations, may be intermediate between the icosahedral phase and a normal crystal.

High-resolution X-ray powder diffraction measurements (P. Bancel, University of Pennsylvania) provide data for quantitative tests of various theories of icosahedral order. The X-ray diffraction peaks are described by an icosahedral indexing scheme with six Miller indices. It is inferred that the positional correlation lengths of several hundred angstroms, extracted from peak widths, are reduced by defects which nevertheless allow orientation order to be maintained across grains with dimensions of 1 μm. High-resolution transmission electron microscopy (R. Gronsky, Lawrence Berkeley Laboratory and L. Bursill, Arizona State University) shows details of the atomic structure. Images formed from the electron diffraction patterns by optical Fourier transformation are remarkably similar to those produced by the quasi-crystal models now developed; 5-fold atomic packing symmetry and defects such as dislocations and stacking faults are observed.

In the best-known theoretical model[3] for these materials, two or more unit cells are packed with unequal spacings to form a 'quasi-crystal' without normal crystalline translational symmetry (P.J. Steinhardt, University of Pennsylvania). Quasi-crystals are much more highly ordered than glasses, but have special symmetries that are impossible for crystals. Remarkably, although quasi-crystals are not periodic, a calculation of the diffraction pattern predicts sharp spots, as with a crystal. In an alternative approach[4] to icosahedral order, quasi-crystalline lattices can be generated by projections from higher dimensions (D. Gratias, CECM/CNRS); the icosahedral lattice is generated by projecting a six-dimensional hypercubic lattice onto three dimensions. This mathematically elegant approach allows a straightforward calculation of X-ray diffraction intensities.

High-resolution transmission electron micrograph of 5-fold plane of quenched 6:1 Al-Mn. Bar, 2nm (courtesy R. Gronsky and L. Tanner).

In another approach[5-7], based on Landau's theory of the emergence of symmetry during phase transitions such as solidification, the atomic structure is described as a set of mass density waves with adjustable magnitudes and phases. An icosahedral quasi-crystal is generated by six density waves directed toward the vertices of an icosahedron. This method lends itself naturally to calculations of the structural stability, thermodynamics, elasticity and the occurence of defects in the icosahedral phase. A careful treatment of dislocations (D. Levine, University of Pennsylvania) reveals that these defects are considerably more complicated than their crystalline analogues; each dislocation requires two vectors, rather than one, to describe it fully.

Conventional discussions of matter in the solid state which assume either crystallinity or almost total disorder are not easily applicable to quasi-crystals. Future research will address fundamental questions about the nature of vibrations, electron transport, mechanical strength, thermodynamic equilibrium and other properties of these new materials. The immediate challenge for experimentalists is to produce larger, more pure and better-characterized samples; and for theorists, is to develop the mathematical tools needed to deal with this intriguing new state of matter. □

Cell motility

Fast axonal transport dissected

from Dennis Bray

ANYONE interested in cell motility likes to see things move. Electron micrographs have their place, as do two-dimensional gels. But for innocent enjoyment nothing beats a working model. Myofibrils isolated from a muscle contract explosively when ATP is added; bundles of microtubules from a sperm flagellum propagate waves and swim around. Marvellous! And now the machinery driving yet another type of cell movement — that of particle transport in the cytoplasm — has been isolated. As shown on page 245 of this issue[1], and in several other recently published papers, all you really need is a membrane vesicle and a microtubule.

For some time, it has been suspected that microtubules are involved in cytoplasmic transport. Membrane-bound organelles moving through a cell (see figure) are usually close to a microtubule, and drugs that disrupt microtubules often, but not always, paralyse these movements. Whole-cell studies of this kind have now been taken to their logical extreme by the discovery of an organism in which movement of organelles

Cultured chick embryo neurites show fast transport of organelles, some of which are visible as dense particles with phase-contrast optics. These two micrographs show a typical neurite at an interval of 10 seconds; the arrows denote an organelle which has moved along the neurite. Scale bar, 15 μm. (Courtesy of P. Hollenbeck.)

is confined to a single microtubule[2].

The organism was discovered on the sides and bottom of a freshwater aquarium in Berkeley, California. Fortunately, whoever found it must have been something of a naturalist, as they welcomed the intruder with a microscope rather than a scrubbing brush. The organism was composed of an enormously branched network of fine threads in which myriads of tiny, phase-dense particles streamed. Following a natural line of enquiry, the threads — subsequently identified as the giant freshwater amoeba *Reticulomyxa* — were examined in the electron microscope and found to resemble nothing so much as the thin processes of nerve cells. Like axons, each cytoplasmic thread contains aligned microtubules, and some are so thin that they contain but a single microtubule.

Correlating their light- and electron-microscope observations, Koonce and Schliwa were able to show that the phase-dense organelles, most of which are mitochondria, can move even in threads that contain only one microtubule[2]. Moreover, they can move in either direction, despite the fact that the microtubule is certain to have a distinct structural polarity. The authors conclude that explanations of organelle movement based on the beating of myosin crossbridges in muscle, or of the dynein side-arms in a cilium, both of which produce unidirectional forces, are not to be accommodated wholesale.

But any cell, no matter how attenuated, is still something of a black box. Three years ago, a far more accessible system was described that allows the rapid transport of vesicles to continue in the absence of an outer cell membrane[3]. Axoplasm is extruded from the giant axon of a squid and then examined by video-processed polarization-based light microscopy. With this exciting and powerful method, it is possible to see swarms of tiny vesicles, 0.2 μm or less in diameter, scurrying about their business in the axoplasm. If the axoplasm is spread even more thinly the vesicles can be seen moving along individual fine filaments, the nature of which forms the subject of two papers recently published in *Cell*[4,5].

Organelles ranging in size from mitochondria down to the smallest vesicles all move along 'transport filaments' in the extruded axoplasm at steady rates of about 2 μm s^{-1}. Unlike the movements in intact axons, large organelles travel as quickly as small ones, and the movements are smoothly continuous, lacking the saltatory, stop-and-go motion long considered the hall-mark of cytoplasmic particle transport. The difference, presumably, is that in the intact axon many organelles are obstructed by other components of the cytoskeleton. Most importantly, the transport filaments, although no more than 25 nm in diameter, are clearly revealed by the high-technology light microscope to be microtubules. Treatment and examination of the filaments by immunofluorescence and by electron microscopy shows that they contain tubulin (and not actin) and that they have the unmistakable substructure of microtubules.

Given these observations, what experiment would you like to see performed next? If your answer is to test whether movement is regained when separated vesicles and microtubules are reconstituted, turn to the paper by Gilbert *et al.* on page 245. Rather than try to separate microtubules from axoplasm, they used the ready-made parallel bundles of microtubules in the flagella of sea-urchin sperm. Freed of their outer membrane by detergent and dialysed against low-ionic strength solutions to remove most of their dynein side-arms, these readily available bundles present smooth straight tracks of uniform (and known) polarity. Gilbert *et al.* show that vesicles recovered from the squid axon travel smoothly, rapidly, without interruption and (as in both the giant amoeba and isolated axoplasm) in either direction along these tracks. Because movements proceed in the absence of most of the dynein arms, and because they ignore the intrinsic polarity of the ciliary axoneme, it is unlikely that the vesicles are moving by the same machinery that drives the cilium. More and more it seems that each organelle must have its own power source, like an outboard motor, that can drive it in either direction along a microtubule. The motor does not resemble that driving muscle contraction or ciliary beating; so what might it be?

Close on the heels of all these studies comes yet another instalment in the unfolding story. Vale and collegues[6] have now developed a reconstituted transport system in which the components are split not just two ways, but three. Membrane organelles from squid axoplasm constitute one part, and isolated microtubules the second — in this case purified from squid optic lobe tubulin. But the third component is the most exciting: a soluble, heat-labile, trypsin-sensitive extract without which nothing moves. Addition of this extract enables not only organelles but also polystyrene beads to travel along microtubules. It even causes the microtubules themselves to glide over the surface of a glass coverslip, looking like miniature snakes. Any speculation as to the nature of the mechanochemical protein in the soluble extract is clearly redundant; the answers are surely already in the press. □

Thunderstorms

Wind shear and aviation safety

from Edwin Kessler

THAT aircraft should avoid thunderstorms is advice as old as flying itself. Although airborne weather radar provides a means of inflight evaluation of the weather, flight through echo-weak areas of thunderstorm complexes has led to several fatal and highly publicized accidents. All but three of the twelve such accidents between 1940 and 1970 followed a catastrophe at substantial altitude. With subsequent emphasis on the use of radar for avoiding storms, the incidence of accidents initiated at altitude declined remarkably. Since 1970, US aircraft have been involved in seven more fatal thunderstorm-related accidents, but five of these occurred during takeoff and landing and have been attributed to strong wind shears, mostly associated with thunderstorms near airports. There have also been other disturbing incidents during aircraft operations near terminals. The focus of research has accordingly shifted to the study of both thunderstorm downdrafts and outflows (downbursts) and of the strong variations of horizontal wind that accompany intense warm fronts[1].

Whereas aircraft used to bounce around a lot in bad weather, like leaves in a storm, today's planes are more sensitive to larger-scale atmospheric phenomena. The typical 1950s propeller-driven transport had a relatively low wing loading: it flew about 300 m.p.h at altitude and about 100 m.p.h on landing. The reciprocating engines responded within about 2 seconds to pilot inputs. Today's commercial transports fly at about 600 m.p.h at altitude and 150 m.p.h at landing and takeoff, and their engines take up to 7 seconds to respond fully to pilot inputs. Thus, during takeoffs

and landings, the 1950s aircraft would have flown about 300 feet before the engines responded; today's aircraft fly about 1,500 feet. And today's runways, about 10,000 feet long, twice the length required for a typical piston-engine aircraft, indicate the extended exposure of modern commercial aircraft to boundary-layer phenomena during takeoff and landing.

The variation of wind divided by the distance over which the variation occurs is the wind shear: mathematically, the shear is a tensor whose nine components correspond to the three orthogonal directions in which the wind variations can occur, combined with the three directions from which the wind can be blowing. The pilot is most interested in wind and its variations in the directions of flight, and in the vertical wind, because these produce the principal lift forces. Small-scale shears, termed turbulence, can produce discomfort, but if an aircraft enters a region of much reduced headwind during takeoff or during approach to landing, loss of lift is a serious safety concern. This is exacerbated when a downdraft is encountered along with a sudden unfavourable change of horizontal wind speed. In a severe downdraft outflow, with wind variation around 20 m.p.h per 1,000 feet, decline of headwind and downdraft can cause irreversible loss of altitude to the point of a crash. This is most likely during takeoff or landing when a thunderstorm is over or near the airfield, but can also occur with solitary atmospheric waves.

As a result of several incidents beginning in the late 1960s, the Federal Aviation Administration (FAA) issued a series of advisory circulars on the hazards of thunderstorms and wind shear, and developed new instrumentation for use at airports. Until the late 1970s, surface winds at air terminals were reported by a single centrally located anemometer. Guidance from a single device is inadequate in the jet age, especially when winds vary by 50 m.p.h or more from one side of an airport to the other, and such variations can even occur in clear air and without local visual clues. In 1976, the FAA developed the Low Level Wind-shear Alert System — a system of multiple anemometers with a display and alarm system that notifies the control tower operator when any one of the anemometers indicates a wind speed different from the centre field wind[2]. The efficacy of the system is suggested by the fact that only one fatal accident (in July 1982 at New Orleans) has been attributed to wind shear in an airfield with the equipment. About 60 airfields now have the basic system, and there are plans for installation at 50 more. The installations at Denver and New Orleans are being upgraded by adding extra, more closely spaced anemometers.

Substantial study continues to refine our knowledge of low-level wind-shear events, their individual and statistical characteristics, climatology and predictability. Downbursts and microbursts are being studied in the Chicago area[3,4], at laboratories of the National Center for Atmospheric Research and the National Oceanic and Atmospheric Administration (NOAA) at Denver, Colorado[5], and at NOAA's National Severe Storms Laboratory at Norman, Oklahoma[6,7]. Downdraft outflow phenomena are unusually frequent and intense at ground level in the Denver area. There they are often abetted by a layer of rather dry air on and near the ground, having a steep lapse rate of temperature. Such a boundary layer tends to amplify any thunderstorm or shower downdraft, especially with the strong evaporative cooling that accompanies precipitation from scattered showers. Findings from the Denver-based projects JAWS (Joint Airport Weather Studies) and CLAWS (Classify, Locate and Avoid Wind Shear) have both theoretical and practical implications. Downdrafts strong enough to be classified as microbursts around Denver are often 0.5-1 mile in diameter, and typically last 5-15 minutes, although occasionally they develop significantly within one minute. The difference between peak winds on opposite sides of outflow on the ground at the time of maximum development is about 55 m.p.h. In summer, there is on average one microburst a day within 14 miles of Denver airport.

Further work seek to develop cost-effective systems, both for observing hazardous microbursts in appropriate detail and for communicating the information to pilots at the time of landing and taking off, so that accidents will be avoided and economies are achieved in the use of time and fuel. Observed atmospheric extremes are also being programmed in flight simulators to evaluate aircraft control strategies for mitigating effects of extreme shear during unforeseen encounters.

Other atmospheric phenomena hazardous to flights at low altitudes include solitary waves, strong vertical shear of the horizontal wind and vortices rotating around vertical axes along gust fronts. Solitary waves can retain significant intensity while propagating for hundreds of miles in a stable boundary layer; when the air is dry they may be practically invisible, but under suitably moist conditions they are marked by a line of cloud that may have a deceptively innocuous appearance. They have been especially targeted for research in north-eastern Australia, where they are known as 'morning glories' and are quite common before noon[8]. In the United States they sometimes develop from thunderstorm gust fronts that propagate in a stable air layer ahead of the originating disturbance[9].

Intense warm frontal shear — a variation of the horizontal wind with height — especially when accompanied by poor visibility in rain and fog, can cause a descending aircraft to land short of the runway — as happened on 17 December 1973 at Logan Airport, Boston[10]. This outcome of extreme conditions can usually be averted by timely advice to the pilot on wind speed and direction at different altitudes. Doppler radars can provide this and other detailed wind information routinely, at intervals of a few minutes[11,12].

Future weather-surveillance systems for airports will probably include surface anemometers and Doppler radar, and possibly a lightning-locating system. It will be essential to collect data at a central location and to process them there for communication to pilots. As technology advances, we can expect an improved match between timely displays of processed meteorological data, actual wind and weather, aircraft capabilities, and pilot performance[13-15]. □

100 years ago

Paradise Found. The Cradle of the Human Race at the North Pole. A Study of the Prehistoric World. By William F. Warren, S.T.D., LL.D., (London: Sampson Low and Co.)

IT has come to be an understood thing that when geologists or biologists propound theories as to past stages of life on the earth, and these theories attain to a certain popularity, some theologian shall twist the words of the Book of Genesis into a new interpretation, to show that this was what the inspired author meant all the time. A fresh musician has set Moses to dance to a new scientific tune. Since the publication of well-known modern views as to the diffusion of plants and animals from the Polar Region, it was to be expected that we should have a book proving that man was created in an Arctic Paradise with the Tree of Life as the North Pole; and here the book is. Other ancient cosmologies, such as the Greek and Indian, are made to bear their not always willing testimony. The commendatory letters published from Professors Sayce, Tiele, and Whitney do not at all imply that these eminent scholars countenance the Polar Paradise doctrine. The author seems to have sent them a paper on "Ancient Cosmology and Mythical Geography," their acknowledgements of which they are now perhaps hardly delighted to find as certificates in a "Paradise Found."

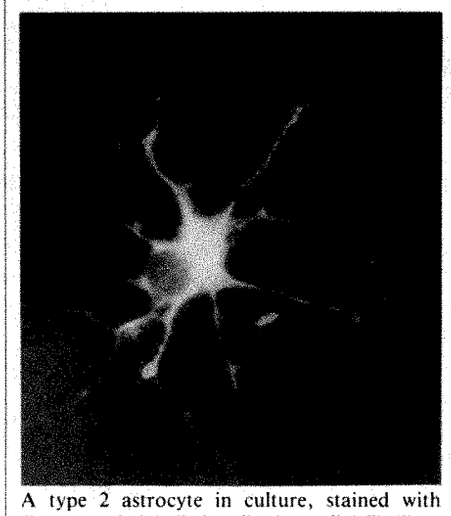
Neurophysiology

Potential challenge from glia



from A.R. Gardner-Medwin

THE neurones in our brains are required, as we all know, for the complex information-processing tasks of everyday life. Roughly an equal amount of space in the brain, however, is devoted to glial cells, chiefly astrocytes and oligodendrocytes, whose functions are diverse and poorly understood. Glial cells offer many challenges in understanding the overall function of nervous tissue, just one of which is their intriguing electrophysiological behaviour. Several recent papers[1-5], including one on page 229 of this issue by Bevan and Raff[1], show that glial cells in culture sometimes have hitherto unsuspected membrane characteristics, including high permeability to potassium, higher membrane conductance than resting neurones, direct electrical connections with one another, and the ability to respond metabolically to depolarization induced by local neuronal activity, all of which add to their fascination. How far these properties are characteristic of glial cells *in situ* is still a matter for conjecture.

The electrophysiological study of glial cells in tissue culture began in 1958 with work of Hild, Ching and Taskai[6] who showed that morphologically identified glial cells do not display the action potentials that are characteristic of most neurones, yet have resting potentials that are sensitive to potassium. Over the years, with contributions from many people working on both isolated cells and intact tissues, a picture has emerged in which some glial cells have very remarkable properties[7-10], including probably the most extreme selectivity of membrane permeability for potassium over sodium of all known biological cells.

One aspect that is beginning to be well characterized is the role of glial cells in stabilizing extracellular potassium levels in the nervous system[11-15]. Many questions remain, even in this highly specific area. For example, the relative importance of potassium dispersal through glia and of net uptake into glial cells remains controversial. The principal mechanisms of net uptake are uncertain and the significance of all these mechanisms for normal neural function are largely subjects for speculation. These current issues would tax one's ingenuity enough in designing experiments to settle them, even without the addition of the surprising new data from studies on isolated glial cells in culture.

The special advantages of work in tissue culture are that the cells can be studied in a simplified context and with the widest range of modern cell biology techniques. These include antigenic characterization with monoclonal antibodies and 'patch' electrophysiology, in which a pipette is sealed tightly to the outside of the cell membrane. Because glial membrane conductance is largely a potassium conductance in most preparations, it is gratifying that K^+-selective single channels (with, interestingly, a variety of different sizes) have been identified in oligodendrocytes[2]. The observed channels open and shut intermittently, although any channels that are constantly open may perhaps have escaped detection for technical reasons.

A type 2 astrocyte in culture, stained with fluorescently labelled antibody to glial fibrillary acid protein (courtesy of Dr. J. Cohen).

First of the particularly novel glial characteristics to emerge are sodium-selective[3] and calcium-selective[4] conductances, revealed with various pharmacological interventions. Astrocytes treated with barium and tetraethylammonium ions can even produce action potentials, involving Ca^{2+} channels[4] and with some resemblance to action potentials of heart muscle. Voltage-dependent sodium[5] and potassium[1] conductances, comparable with those normally found in neurones, have now been demonstrated in apparently normal, well-characterized astrocytes in culture (see figure). Despite many electrophysiological studies of cultured astrocytes[7], such potentials have not previously been reported, so there would seem to be substantial variation in properties between glial cells in different laboratories, and even to a certain extent among cells prepared in a single laboratory, with consistent techniques[5]. The reasons for these differences are obscure, but an important consideration may be that the cells for which results are illustrated in Bevan and Raff's study[1] seem to have much higher input resistances (100-150 MΩ) than have been found before (usually 1-10MΩ). It is not clear whether this could be explained by morphological differences, variations in the extent of coupling between cells or aspects of the recording conditions that may affect the membrane conductance. The new findings[1-5] do show convincingly, however, that some glial cells are capable of producing the molecules, presumably proteins, responsible for various different channels found in membranes.

At least three suggestions can be made as to the possible functional significance of voltage-dependent channels in cultured glial cell membranes. They might have no functional significance at all, appearing only as a consequence of particular culture conditions; they might exist in mature glial cells *in vivo* and play some physiological role; or they might exist only transiently in glial cells and play some role in the development or maintenance of neurones[5]. Because the channels are opened only when the membrane is depolarized above about −40mV, they could function solely in conditions leading to extreme glial-cell depolarization.

Such extreme disturbances are known to occur only in two pathological conditions: spreading depression, a condition believed to occur in some migraine attacks[16], and anoxia. The potasium conductance of glial cells may play a significant role in preventing spreading depression[17,18], which would indeed be assisted by a conductance increase on depolarization, but none of the studies *in vivo* has yet revealed a class of glial cells with non-linear conductance[7-10]. The recent studies on cultured glial cells may spur attempts to tackle the substantial technical problems that will be encountered before such cells can be identified with certainity *in vivo* and distinguished from neurones. □

Erratum

In the article by Jonathon Bacon 'Why flying locusts do not crash' (*Nature* 9 May, p. 94), the fourth paragraph in colunm 3 should begin "The descending neurones make only weak direct connections with flight motor neurones but have strong inputs..."

Atmospheric physics

Predicting the ionosphere

from D.G. Cole

THE status of the ionosphere — modelling, measurement techniques, applications and forecasting of the ionized upper atmosphere — was discussed recently at a conference held under the auspices of the Australian Ionospheric Prediction Service in Sydney*. Regarded by some as an anachronism, ionospheric research has enjoyed a resurgence of interest to cope with a demand for high-speed digital data traffic on ionospherically propagated paths, increased high frequency (3-30 MHz) radio communications in developing countries and trans-ionospheric propagation problems.

The fundamental tool of the ionospheric forecaster is an ionospheric model. The present status of such modelling was reviewed by J. R. Dudeney (British Antarctic Survey). At present the most widely accepted model is the International Reference Ionosphere (IRI) (eds Lincoln, J.V. and Conkright, R.O. NOAA Report, Boulder, 1981) which is distributed on magnetic tape. IRI gives profiles of electron and ion density, temperature and relative ion composition; a user supplies location, time of day, season and solar activity. The model is used widely, even though it is inapplicable to auroral zone regions and times of very high solar activity, and does not consider irregularity structures.

The two regions that still provide the greatest problems in any modelling or prediction schemata are the equatorial and polar/auroral zones. Of these, the equatorial region is the easier to model. Indian researchers have gathered much decisive data by widespread low-cost satellite-beacon scintillation and electron-content studies. The IRI model has been shown to underestimate considerably the low-latitude F-region — the ionospheric layer of maximum electron density at about 300 km above ground level — daytime plasma density scale-height and total electron content. Disagreement with the topside ionosphere is bad, which is relevant to transionospheric systems and, through vertical plasma transport, to HF ionospheric systems.

Total electron-content predictions can be improved by using theoretically calculated profiles, but this is prohibitively time-consuming and expensive even with present-day large computers. D.N. Anderson (US Air Force Geophysics Laboratory) and coworkers have recently made considerable progress with a semi-empirical low-latitude ionospheric model that uses only coefficients from such theoretical profiles to form the basis of a fast portable computer code to produce realistic low-latitude F-region electron-density profiles.

The polar region and the behaviour of irregularities still remain a world-wide problem, requiring concerted intensive global data collection and analysis. An exercise which can be regarded as a forerunner of such a study, project SUNDIAL, was conducted late in 1984. The project arose because there was no prediction capability for day-to-day variations in ionospheric structure and it highlights the fact that the various ionospheric domains are not isolated subsystems, but are indeed interactive elements in the entire solar-terrestrial network. The project looks to progressive development of a genuinely predictive ionospheric specification capability under both quiet and disturbed conditions. Such a capability would add direct solar and magnetosphere inputs as well as latitudinal and longitudinal coupling to the fundamental ionospheric model, and requires near real-time updates from a responsive network of ionospheric monitoring stations.

The experimental period of project SUNDIAL was based on an eight-day flight of the space shuttle carrying a 1.28-GHz ground imaging radar in October 1984. This aperture-synthesis radar requires phase-path constancy through the ionosphere to obtain maximum resolution. During this period the international ground-based ionospheric programme (coordinated by E.P. Szuszczewicz, Science Applications International, Virginia) collected ionogram, electron content and scintillation data from equatorial, mid-latitude and both polar domains, later supplemented with data on solar, magnetospheric, geomagnetic and interplanetary activity. Two workshops are planned in 1985 to analyse these data and to issue guidelines, recommendations and suggest follow-on programmes. Future studies will emphasize new programmes and also the appropriate coordination to ensure that diverse existing ionosphere measurement facilities are fully used. Interestingly, the USSR Solar Terrestrial Physics group was the first to propose an intense global ionospheric study.

A final note of interest is the detection of meteor echoes by the Australian Project Jindalee, an Over-the-Horizon Backscatter Radar near Alice Springs. Conventional radar meteor studies, starting with the early work at Jodrell Bank in 1945, have always used only the direct line-of-sight return signal. It seems now that, for the first time, significant rates of meteor echoes have been detected by various ionosphere (and ionosphere-ground) reflection modes. R.M. Thomas (Project Jindalee team) also suggests that the steerable, narrow beam-width antenna pattern, coupled with the frequency, agility and sophisticated processing available to the system, can be used to optimize the radar for a particular meteor radiant by changing the appropriate parameters. Such a facility could significantly revitalize interest in delineating the faint-field meteor influx and improve the management of polar high-speed meteor forward-scatter links of interest to military and other circles. □

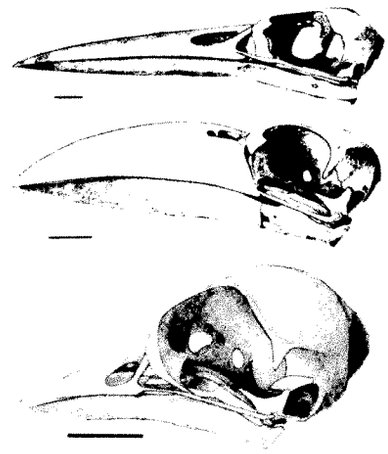
Evolution

The point of a toucan's bill

from J.S. Jones

MODERN evolutionists are beguiled by random change. Recent theories about DNA sequence divergence suggest that natural selection does not determine the fate of most genes and that genetic drift is the main agent of evolution, with selection acting only to remove harmful mutations. It is therefore important to remember that not all evolution happens by accident; that natural selection is a potent force for adaptive change, and that its products can be seen all around us. Some of the most spectacular examples of the intensity of natural selection and its ability to produce rapid adaptation have emerged from recent studies of birds ranging from the mundane sparrow to the outrageous toucan.



House sparrows were introduced into the United States in 1852, and are now widespread. Since their introduction, American sparrow populations have undergone considerable morphological evolution, and northern birds are larger and have relatively shorter extremities than do those in the south[1]. These differences are maintained in the face of dispersal sufficient to produce relative uniformity in the frequencies of genes coding for soluble enzymes[2]. They probably represent an adaptive response to climatic selection: birds with short limbs survive in cold weather considerably better than do those with long. In one particularly harsh Kansas winter a 25 per cent difference in mean fitness was associated with humerus length[3]; a difference related to the extent of heat loss through the extremities. Larger males, but small females, are better at surviving the winter — an effect which might result from an advantage of more dominant males and more submissive females in conditions where fighting is metabolically costly. Differences in food items selected by birds of different body size may also help to ex-

plain the greater sexual dimorphism found in northern populations[4].

Natural selection appears to be an effective agent in producing rapid adaptation in these introduced populations. There is no information on the genetic basis of morphological variation in sparrows, but transfer experiments with other American birds suggest that some geographical changes in body form are a direct response to the environment[5]. Consequently, estimates of heritability are needed before the evolutionary significance of such changes in morphology can be assessed. As recently discussed by Paul Harvey[6], information of this kind is now available from new work on Darwin's Galapagos finches[7].

Patterns of differentation in their soluble enzymes suggest that the finches have occupied the islands for less than a million years and have diverged rather rapidly from the emberizine finches that are their mainland ancestors[8]. There are striking morphological differences between species, from the long slender bill of *Certhidia olivacea* to the stout and powerful beak of *Geospiza magnirostris*. Assuming there is no strong correlation between genetic and environmental variation in wild birds, family studies suggest that the heritability of morphological characters, such as body size or beak dimensions, is high[7,9]. For example, three quarters of the overall variation in *G. fortis* body size is due to genetic variation. There is therefore abundant genetic variation on which natural selection might act. Periodic droughts, such as those on Isla Daphne Major in 1977, 1980 and 1982, can lead to mortality rates of 85 per cent. Much of this is selective, and adult survivors have substantially larger bodies and beaks than those who die, probably because they can feed better on the hard seeds that persist through the drought. A selective shift of six per cent in morphological traits can occur in one year[10].

Selection of this intensity, acting on highly heritable characters, has the potential to generate rapid morphological change. A new study of the numbers of finch species on the various islands and their patterns of differentiation in beak shape in relation to food availability shows that coexisting species always differ in bill dimensions by at least 15 per cent. Such differences can be explained only by interspecific competition and by local adaptive radiation into a variety of feeding niches[11]. The role of competition for food in driving adaptive radiation is particularly manifest when comparing the morphology of species present in sympatry and in allopatry on different islands. The bills of *G. fortis* and *G. fuliginosa* diverge from each other to a much greater extent in mixed populations than in single-species populations. Comparing of feeding behaviour with availability show that this character displacement results from exclusion from particular food items in mixed populations, leading to a change in optimal beak size for each species[12]. Natural selection on beak form appears to be intense enough to bridge the gaps between existing species within only a few years. This evidence that selection is the directing force in evolution on the Galapagos contrasts with the emphasis placed on accidental change in evolutionary studies of Hawaiian *Drosophila*[13].

Adaptations in skulls of Coraciform and Piciform birds. Top to bottom: *Alcedo atthis* (kingfisher); *Selenidera langsdorffi* (toucan); *Sasia abnormis* (piculet). Scale bars, kingfisher and piculet, 10mm; toucan, 5mm (from ref.17).

Adaptive radiation has the potential to obscure patterns of taxonomic affinity if unrelated organisms, living in ecologically similar circumstances, evolve body forms sufficiently alike to produce an appearance of common ancestry[14]. This is true to some extent among Galapagos finches[15], but is far more striking among Australian birds. The Australian passerines include many species with names (wrens, crows, babblers and honeyeaters) reflecting their similarities in structure and behaviour to birds in other parts of the world. Until recently, this diversity was thought to reflect a series of invasions of Australia by a number of unrelated ancestors. Now, however, the use of DNA hybridization to measure genetic affinity suggests that it results from an explosion of adaptive radiation from one endemic ancestor within the past 60 Myr[16], to fill the niches occupied by wrens, warblers, flycatchers and chats in other parts of the world. Unique forms such as bowerbirds, butcherbirds and bellbirds have also evolved. Once again, natural selection in diverse habitats has led to a rapid adaptive response.

Comparisons of structure and of ecology have recently been combined to illustrate the forces of natural selection that have led to an exuberance of form in a group of birds far more diverse than sparrows, finches or Australian passerines[17] (see figure). The Coraciiformes and Piciformes include 15 families. Some are familiar — kingfishers, bee-eaters, woodpeckers and toucans; others are less well known — todies, cuckoo-rollers, jacamars, barbets, puffbirds and piculets. Despite their name, most kingfishers do not fish. Instead they sally for terrestrial prey, which may include small snakes. The beak is large and stout — which is perhaps not surprising given that some species nest in tunnels excavated by flying directly at a river bank. Bee-eaters pursue insects on the wing, and can catch up to 350 in a single day. Their bill is less heavily constructed than the kingfisher's but is not as lightly built as that of the hoopoe, which probes the soil for insects. The huge beak of the hornbill is used to crush dangerous prey and to peel fruit; food items, once prepared, are tossed into the air and caught in the bird's open mouth. Honeyguides have a short but robust bill and can feed on wax. The huge casque of the toucan is used to peel fruit, but may also be useful in intimidating other birds when robbing their nests, and as a social signal. Finally, the wrynecks, piculets and woodpeckers feed on insects obtained by probing or excavating with a straight chisel-like bill. This diversity of skull form is accompanied by an equivalent radiation of the muscles of the head and neck, which are reduced in bee-eaters, but massively strengthened in woodpeckers. Other specializations include the extremely small tongue of kingfishers and the brush-like tongue of the toucan, which is among the largest in any bird. This rare combination of information on structure, ecology and behaviour in a widely distributed and highly variable group gives an unusual insight into the power and opportunism of selection in leading to adaptive change.

In 1825, Sydney Smith wrote of the toucan: "To what purpose is a bird placed in the forest of South Cayenne, with a bill a yard long, making a noise like a puppy dog, and laying eggs in hollow trees? The toucans, to be sure, might retort — to what purpose were gentlemen in Bond Street created? ... There is no end to such questions. So we will not enter into the metaphysics of the toucan." Smith was hasty in his dismissal of this enigmatic bird: modern ornithology reminds us that molecular biology is still little more than an account of the structure of the genome, and that we should be wary of abandoning natural selection as an agent of change until we can describe the functional anatomy of molecules in as much detail as is now possible for beaks, muscles and feathers. □

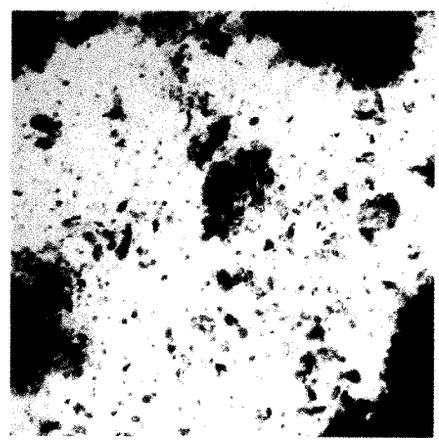
Plant geology



Changing weight of photosynthesis in the ocean

from I. Gilmour

ON PAGE 216 of this issue Arthur *et al.*[1] provide further evidence for the debate on what controls the carbon isotope composition of organic matter in marine sediments. The common photosynthetic pathways discriminate against the heavy carbon isotope (^{13}C), mainly as a result of a kinetic isotope effect inherent in carbon fixing reactions. As carbon dioxide dissolved in seawater contains more ^{13}C than atmospheric carbon dioxide, marine organic carbon is generally isotopically heavier — that is, ^{13}C enriched — than most land plants or terrestrial carbon. This has led to a general belief that the variations in the carbon isotope composition of organic matter in marine sediments provide a measure of the relative amounts of marine and terrestrially derived organic matter[2,3]. Arthur *et al.*, however, now report an apparent reversal of this general trend in some marine sediments of Cretaceous and older ages[1] (see figure). Using a second, independent, geochemical parameter to evaluate the source of the organic matter, they report carbon isotope values for rocks apparently containing mainly marine organic matter that are lighter (that is, more ^{13}C-depleted) than those containing mainly terrestrial organic matter.

The parameter that Arthur *et al.* have measured is the hydrogen content of the organic matter, determined using the Rock-Eval pyrolysis method, which provides a 'hydrogen index' related to the H/C ratio in the organic matter[4]. Terrestrial organic matter has a lower H/C ratio compared with marine organic matter because of the presence of lignin. This material, which gives land plants their 'woody' characteristic but is not found in marine algae, has a low H/C ratio, reflecting its more aromatic chemical structure. Arthur *et al.*, by plotting the carbon isotope composition of the organic matter against the 'hydrogen index' or H/C ratio, relate organic carbon isotope values to the chemical composition of the organic matter, which in turn is dependent on the relative contributions of marine or terrestrial material. Using this approach, they are able to demonstrate that for Cretaceous and older organic rich sequences a negative correlation is commonly found, suggesting that the lightest carbon isotope values are related to chemical compositions that indicate the greatest contributions of marine organic matter. For the more recent Cenozoic sediments, they observe either a positive correlation or no correlation, reflecting the 'normal' isotope variations between marine and terrestrial materials and purely marine organic matter, respectively. Thus, pre-Cenozoic marine organic matter is anomalously depleted in ^{13}C by around 5 to 7 parts per thousand compared with marine organic matter in more recent sediments.

Anomalous ^{13}C depletions in ancient sediments are fairly common, particularly in Precambrian sediments[5-7] where different carbon cycling pathways, notably those based on methane, have been invoked to explain them. It is difficult to try to explain such anomalies in ocean sediments, where the organic matter is derived predominantly from phytoplankton that use carbon dioxide. Arthur *et al.* consider several possibilities for this anomaly. They discount diagenetic effects, which generally do not produce sufficiently large shifts in the carbon isotope composition of the organic matter. They also eliminate, although not totally, the possibility that changes in the carbon isotope composition of the organic matter reflect changes in the dominance of marine phytoplankton groups because this explanation is not supported by the Cenozoic palaeontological record. The three remaining possibilities all relate to one factor, the level and isotope composition of dissolved carbon dioxide in the oceans and its possible effect on photosynthesis. The authors eliminate a secular variation in carbon isotopes because the average Cretaceous carbonate is about 1.5 parts per thousand heavier than modern pelagic carbonates, which would result in marine organic matter being heavier, not lighter. Thus, the favoured interpretation is as follows: increasing the carbon dioxide concentration in the oceans can have a profound effect on photosynthesis. Photosynthetic carbon isotope fractionation is maximized under conditions of high carbon dioxide availability[8,9] and, as Arthur *et al.* point out, this would result in ^{13}C-depletion of organic matter. An increase in carbon dioxide availability can be accomplished by reducing the ocean temperature, which increases the solubility of carbon dioxide. But the Creteaceous oceans were as warm, if not warmer, than present-day oceans. Thus, Arthur *et al.* argue that possible higher levels of atmospheric carbon dioxide during the Cretaceous, combined with lower levels of surface productivity, would have resulted in more available carbon dioxide and increased fractionation of the carbon isotopes found in marine plankton.

Organic material from a Cretaceous black-shale sequence from the Falklands Plateau, South Atlantic, which has revealed lighter carbon isotope composition than expected. The material is predominantly the remains of photosynthetic marine algae with minor amounts of material derived from the continents of the time. (Photo courtesy of I. Gilmour.)

Are these intepretations correct? If so, then modern marine photosynthesis may be occurring under geologically unusual conditions. True or false, their approach is certainly on the right lines. By relating carbon isotope composition to H/C ratio and hence to chemical structure, the relative contributions of marine and terrestrially derived material are better understood. However, the carbon isotope values obtained still represent an average of two components, whereas ideally the marine and terrestrial material should be resolved completely. Failing this, the approach adopted by Arthur *et al.* is certainly an improvement on merely measuring bulk carbon isotopes in isolation. The implication from this work is, as the authors suggest, that carbon isotope values alone are not reliable for organic matter provenance studies, particularly in pre-Cenozoic sediments.

The possibility of fairly substantial variations in marine carbon isotope values resulting from variable photosynthetic fractionation is worth much closer investigation. Positive carbon isotope shifts in carbonates during the Cretaceous could represent increased oceanic productivity that uses up more of the lighter isotope[10]. The work of Arthur *et al.* could upset some of the widely accepted ideas for models of the carbon cycle. Clearly, more detailed work is required, but merely taking bulk carbon isotope values of organic matter in sediments in isolation is not going to help solve the problem. □

Scientific creationism and rationality

from Michael A. Cavanaugh

Scientific creationism is a social movement of rationalists — amateur philosophers of science — whose claims upon science policy are nonetheless wholly unreasonable. This thesis may not endear the author either to rationalists or creationists, but it may illumine the movement's behaviour and the sources of its wider appeal.

ORDINARY language contrasts the rational and the social. Individuals either pursue the truth or we pursue our intersts; either we have good reasons or we are swayed by others — peers, experts or traditions. On another point of view, derived from the sociologists Durkheim and Weber, society is defined by its shared rationality. Social structures and divisions of labour can distribute, even augment, human reason (or impede it). From this standpoint, society as such is "knowledge-based; and two heads are better than one. This, if so, is so for any society.

Modern societies are knowledge-based in yet another way: they thrive upon mass education[1]. Schooling has become indispensable for even ordinary occupational roles; fairly advanced educational credentials are demanded routinely as tickets of admission to the work force[1,2]. The consequences are political and cultural as well as economic. Complex societies discover that they cannot dispense with technical expertise. And this is no less true (as in Iran and China in recent years) when the power of technicians and experts conflicts with traditional elites or newer populist authority[3,4].

Mass education

Mass education is oddly uneven education. It enlarges society's pool of intellectuals[5], but also confers academic degrees upon people contemptuous of intellect and unfamiliar with the life of the mind. Mass education democratizes educational opportunity; it also stratifies the "new class" of the highly schooled and proliferates an intellectual underworld — Pluto's Republic, *pace* Peter Medawar.

So it is that late twentieth-century society simultaneously enjoys unprecedented levels of education and technical knowledge and suffers acute self-doubt and pessimism about the very value of human reason. "Once again," as Medawar[6] has observed, "there is a rootlessness or ambivalence about philosophical thinking, as if the discovery or rediscovery of the insufficiency of reason had given a paradoxical validity to nonsense, and this gives us a special sympathy for the dilemmas of the seventeenth century."

Michael A Cavanaugh is at the Department of Sociology, Temple University, Philadelphia, Pennsylvania 19122, USA.

How apt, as our era goes through a debate more appropriate to the age of Bacon, Newton and Descartes (or perhaps, of Thomas Aquinas). Claiming support from the scientific community, highly schooled fundamentalist Protestants propose teaching a "creation model" as an alternative to evolution. Since their heyday during 1980-82, such claims and proposals have not gone undisputed. To its opponents, creationism appears as Luddite anti-intellectualism[7]; as pseudoscience[8]; as a deviant science movement[9]; and as an American abberation (rooted in the rural South)[7]. Its advocates are portrayed as equally uninformed about genuine science as about genuine religion[10]; or as "space-age fundamentalists"[11], religious traditionalists as inconsistent as the "republican" *mullahs* denouncing Western materialism into the uplifted microphones of mass-produced tape recorders.

almost all contemporary scientific creationists claim batchelor's degrees forty to sixty per cent in some scientific or technical field

Religious fundamentalism is nothing if not a protest against modern secular society[12]. Yet to regard scientific creationism simply as marginal to that society is misleading. On the contrary, creationism is not the anti-intellectualism of those who have just gotten shoes; it is the counter-intellectualism of modern offspring (who understand well the rhetoric of modern political pluralism). Consider educational experiences. Unlike their forerunners of the 1920s, contemporary scientific creationists are the beneficiaries of mass educational expansion. Almost all claim bachelor's degrees, an estimated 40-60 per cent in some scientific or technical field. Around 10-25 per cent are trained in applied areas, particularly engineering, 20-30 per cent in physical science; and a few (5-10 per cent) in the life sciences, the most relevant for an anti-Darwinian movement. (Some are now completing graduate work pseudonymously.) Many claim PhDs from accredited schools, even major universities. (Some claims have been disputed[13].) Compare this with the average US citizen's 14.2 years of schooling.

In social location, the movement is not confined either to rural margins or to the American South. It thrives wherever Protestant natural theology has spread, mainly throughout the former British Empire (for example, North America, Australasia, South Africa, India, the United Kingdom itself), concentrating in North America (primarily in expanding urban areas, in longstanding fundamentalist enclaves in midwestern and western states and provinces but not in the southern United States)[14].

The geographical and occupational distribution of creationists illustrates how fundamentalism is expanding beyond its marginal enclaves. Erstwhile fundamentalists separated themselves into subcultures with unaccredited theologically-based schools[12]. Like their secular contemporaries, today's fundamentalists seek technical credentials for occupational mobility; thus they must neutralize the worldly blandishments from which their forebears simply fled[15]. *Pace* Snow's "two cultures"[16], young fundamentalists desire (and their parents encourage) technical training with minimal humanistic education. Thus the Reverend Mr Jerry Falwell (the leader of the Moral Majority) and Mrs Phyllis Schlafly (the lawyer opposed to expanding womens' rights) wish their children to become engineers. Why? Because, the parents reason[17,18], unlike law (not to mention literature, or philosophy), engineering devises simple solutions to practical problems, without seriously challenging the intellectual traditions of any subculture (religious, political, or otherwise). Questionable though their analysis of engineering may be[19,20], this does suggest why technical training appeals to fundamentalists — Christian, Jewish, Muslim — and others (in developed and developing nations alike) seeking to avoid the choices underlying modern science and technology.

Like Islamic republicanism, scientific creationism is not simply backwardness; both are cautious bargains with the devil, modernity. Although creationism's conceptual resources betray a seventeenth-century provenance, its causes (and appeal) are discernibly more recent; and it is not entirely foreign to the normal culture of science. Why does the knowledge-based society respond to creationism *redivivus*,

rather than to Taoist alchemy or Babylonian cosmology? And why are there so many Islamic republicans but no Islamic creationists? In brief, because the West has a unique history of progressively testing key religious myths for purely secular validity[4], and creationism was tested and found wanting. Because of this legacy, there are some things creationism definitely is not. For instance, it is not preindustrial Luddite irrationalism. It is not a deviant science movement like plate tectonics once was. Nor is it pseudoscience in precisely the way that "psychic archaeology", phrenology or the green cheese theory of the Moon are. Unlike them, creationism once enjoyed standing in the history of science.

Scientific method

Robust in Newton's day, creationism degenerated[21], and no longer informs any active progressing scientific research tradition[22,23]. To survey the main social and intellectual hallmarks that identify science is to discover what creationism lacks. First, knowledge is acquired through conjectures and refutations in a research process[24]. Research is institutionalized in the various scientific professions, which select and certify practitioners, and is communicated in the various journals. Therein research is subjected, first and foremost, to the judgement (and reward) of specialist peers[25]. Subsequent public acclaim or academic standing depends on this judgement.

Second, whence the coherence of science? It cannot be founded upon tenets, which change. Any single tenet may be false; most (the set of all scientific theories minus our present ones) *are* false. Moreover, the foundationalist search for substantive bedrock is now widely acknowledged to have failed[26]. Science acquires coherence, rather, through its procedural commitment to the integrity, reliability and professional governance of scientific theory-testing (and teaching) over the long haul[27]. In other words, modern science rests (like modern law) upon long-term "orthopraxy" (the integrity of method, institutionalized in professions) rather than any short-term orthodoxy of individually trustworthy tenets.

Accordingly, the unit of knowledge acquisition is the theoretical community rather than the individual scientist; thus "science" develops as the distributed property of communities of theory (research traditions), not the consolidated property of individual genius — much less, of what Everyman observes in an untutored way. (On this view, theory is not the luxurious icing on the scientific cake, but the very cake itself. Science is nothing other than the history of its theories, since a method-independent science is impossible, and the subjects of this history are the scientific collectivities that produce and change theories[28,23].)

Third, contemporary science is organized in certain ways. It is "big science"[29]. Science is now conducted typically by career scientists within large complex organizations (rather than as the loosely organized hobby of gentleman amateurs). Increased size refines divisions of labour; consequently, "science" becomes even less the concentrated property of individuals. Each may differ greatly in understanding, talent and skill, yet all may contribute (provided their labour is divided cleverly enough) to the limits of their diverse gifts. Big science is internally "democratized", which permits the fullest use of even modest talent[6,30]. (This is, perhaps, the chief difference between organized science and organized crime.)

The organizational factor makes for a complex relationship of control between science and society. On the one hand, though the typical scientist is not Einstein, he will enjoy some expert divergence from commonsense not shared by every citizen. On the other hand, science and commonsense are not totally antithetical, for in a knowledge-based society, commonsense is increasingly tutored by "packed-down science"[31]. Thus the man on the modern street "sees" the roundness of the Earth, and his common sense "knows" that the heart is not the seat of emotion and that werewolves do not exist. Such "conventional wisdom" is primarily a fact, not of individual psychology, but of membership in a certain kind of society. The organized process of gaining, and warranting, knowledge differs from the ability to use it in packed-down form, or the ability of Everyman individually to validate what he knows.

It is the division of expert labour among a network of complex professional organizations that distinguishes contemporary science from such other enterprises as armchair scepticism, interest-group politics and even the "little science" practised by amateurs (in the best sense) over the centuries past. If such are the hallmarks of science, then it is clear why creationism is not a scientific movement, not even a deviant one. As a rule (with few exceptions), its adherents do not undertake to conjecture and refute through empirical research[32]. They circumvent the normal confines of professions and journals, going "over the heads" of peer researchers and reviewers in favour of other forums such as the popular press, textbook selection committees, legislatures and courts of law[12,33]. Popular acclaim, not expert peer review, is their ultimate court of appeal.

Big science is internally democratized, permitting the fullest use of even modest talents. This is perhaps the chief difference between organized science and organized crime.

While it is true that (in recent decades) creationists have not tried to outlaw evolution, they have sought to establish anti-evolutionary tenets by legal fiat. And characteristically, the campaign for lasting orthodox tenets advances by a straightforwardly empiricist rejection of evolutionary theory, as if theory meant imperfect fact — "part of a hierarchy of confidence running downhill from fact to theory to hypothesis to guess"[34] — something in dire need of extra-scientific correction.

Organized scepticism

Thus, if science is inseparable from self-governing professions, the procedures they institutionalize and (perhaps most importantly) the theories they conjecture and test, then scientific creationism does not resemble science. It requires nothing more arcane than well-known philosophical and sociological demarcations to understand why public policy justly may disregard creationist demands to produce science through political rather than scientific processes.

Faced with this assessment, a sophisticated creationist might invoke his scepticism and empiricism. He might assert that creationism is highly sceptical about tautology in evolutionary theory[35], whereas evolution requires mere faith in insubstantial theories. Does this count? Old chestnuts about tautology, verifiability and naive falsification[36,37] aside, the answer must be no. Why? First, the process of criticism in contemporary science deploys the norm of "*organized* scepticism"[30] seeking cumulative growth in knowledge. Creationist scepticism occurs sporadically outside organized science and seeks selectively to prune whatever accumulated knowledge offends extra-scientific tastes.

Second, categorical "scepticism" masks an underlying foundationalism (religious fundamentalism being the limiting case). Categorical or naive doubt is not scepticism. For doubt to be intellectually credible, the specific occasions and ends of doubt make all the difference. Creationists understand this intuition, for they, too, doubt selectively; as members of the knowledge-based society, their views retain much presupposed common-sensical packed-down science (that the Earth is round; that the heart is a pump; that men do not change into werewolves; that fossils are traces of extinct forms[38,39]). So, during fieldwork[14], one informant complained about a long-distance telephone call to a fellow creationist (one of the few who is also a Flat-Earther): "I do not intend to spend $1 per minute discussing nonsense!" Like most creationists, he doubts — but only those views (scientific, or superstitious) that countermand the foundational tenets of fundamentalist Protestantism.

Creationism is radically against method. Procedure is disregarded in favour of direct access to a science-independent, oracular, God's-eye view of nature (literally so). So why not ignore normal research channels and limit oneself, as creationists do, in the worst tradition of academic scholasticism, to *post factum* pot-shotting? Likewise creationists invoke the rhetoric of scepticism and empiricism. They will assert that such-

and-such an evolutionary finding cannot be replicated in a laboratory[40], or is not the sort of thing publicly observable by the common man[41], or would not meet lawyers' tests of evidence[35], and so is scientifically invalid. But these 'sceptical' arguments are marshalled in the interests of a submerged theological agenda[42]. Thus empiricism and scepticism, ordinarily laudable scientific hallmarks, are directed toward "doxological science"[43], which is not. Like Cartesians, creationists doubt only so as to shore up science-independent foundational certitude; unlike Cartesians, a preterhuman card waits up their sleeves. Moreover, by appealing to individualistic common-sense tests in the court of public opinion, creationists simply misapprehend the ineliminably distributed property of science and scientific theory change. (One of history's little jokes is that the very principled distrust of structured authority and tradition that wed seventeenth-century Protestant rationalism to little science[44] now divorces it from big science.)

Science and parascience

Habitually circumventing the social and intellectual structure of modern science, now inseparably linked by big science as never before, weighs decisively against creationism's scientific standing. If not science, then what? Creationism is neither deviant science nor simply pseudoscience. It is best appreciated as a specialized *parascientific* movement: one whose members operate outside professional channels of research while still concerned with the criticism, use and dissemination of scientific findings. (Philosophers of science are another such group, likewise, other science analysts, scientific popularizers and amateur naturalists such as bird watchers. For various reasons, many modern enterprises are parascientifically tinged; and now even religions typically vie for legitimacy consonant with the cultural authority of science, rther than asserting independent bases of authority[45].)

creationist parascientists run the gamut from Doubting Thomists to Popper-choppers.

Behaviourally, some creationists are amateur naturalists, fossil-hunters for example (and perhaps there are more creationists in North America than in Britain just because there are fewer bird watchers). But on the whole, creationists are amateur, anachronistic philosophers of science, acting (unlike either working scientists or professional philosphers of science) to alter the content of scientific knowledge piecemeal through plebiscite and lawsuit rather than systematically through influencing professional debates and research activities. They embrace a degenerate research tradition. Their classical mode combines a scholastic preference for oracular science-independent knowledge with a quaintly early-modern mixture of Baconian empiricism and Scottish common-sense realism[12,43]. But lately, some creationists have begun to speak of models, paradigms and falsification. Thus creationist parascientists run the gamut from Doubting Thomists to Popper-choppers.

Amateur philosophy

Scientific creationists suffer a philosophy of science at odds with contemporary philosophy of science as well as with contemporary scientific practice. Their departure from science's professions, procedures and organized scepticism in favour of extra-scientific correction of scientific knowledge is at once principled and opportunistic. It is shaped by the scholastic principles of doubting Thomism, which enjoin opportunistic pruning of whatever contravenes orthodox revelation; quite inimical resources (even Popperian philosophy) will be mobilized as opportunity arises.

The terms "philosophical" and "intellectual" here confer no normative dignity, but, as readers of *Nature* will know, the view that creationism is latter-day scholasticism has been disputed. Criticizing Marsden (its main proponent[12,46]), Jukes[47] asserts that the creationist dispute "is not a polite discussion of differences in philosophy", but a fight over the worst sort of obscurantism. Would that politeness precluded obscurantism; in my research experience, creationists are on the whole polite, indeed amiable. But personality aside, to debate creationism is to quit Plato's for Pluto's Republic, and there is much evidence of Jukes' general view.

As a movement, creationism routinely flouts fundamental intellectual norms (obligations, for example, to earn expertise rather than flaunting credentials; to scrutinize allies as rigorously as opponents; to detect and punish fraud among peers; to meet critic's counterarguments; to acknowledge criticism and retract assertions if the criticism cannot be met[7,37,47,49]). This granted, has Jukes claimed any more than that creationists are ungentlemanly intellectuals and bad philosophers? Marsden's contentions that fundamentalism is not anti-intellectualism but a distinct kind of modern intellectual movement, and that creationists are fundamentally Protestant scholastics, stand on their scholarly merits. Jukes has not refuted them; it is not clear that he has even contradicted them. (It is otherwise with Marsden's view that evolutionary theory is usefully understood as "anti-supernaturalistic mythology"[46], to which Jukes also objects.)

To be sure, the entire creationist campaign is populated with figures such as the "textbook watchers"[11] who are textbook cases of anti-intellectualism[48]. But members of movement organizations tend to be counter-intellectuals, and the movement as a whole relies on them to produce its ideology. Religious intellectuals approach science in various ways[14], the chief options being scholasticism and Averroism. These are, respectively, the view that natural knowledge and revealed knowledge mutually corroborate (classically, that the self-same Author wrote the 'Book of Nature' and the 'Book of Scripture', and the view (typically post-kantian) that natural knowledge and revelation treat different domains. For scholasticism, religion is like science, in several ways. First, theology is commensurable with science (whereas, for Averroism, the two are radically incommensurable, and religion is not just lame science). Second, for scholastics, both science and theology are systems of propositional truths; deny any single truth, and the whole system is weakened, perhaps fatally.

Scholasticism inclines towards scientific realism (against conventionalism) and enjoins extra-scientific correction. Creationists are scholastics. Hence they will produce lists[50] of real truths about nature, allegedly anticipated by Biblical writers and only later verified by science. Hence the unspoken premise of creationist rhetoric: "*Even* (name any authoritative evolutionist) admits that X.. " One cannot "admit" novel knowledge, only what every Schoolman already knows. When scientific experts are found to "admit" X, Y, and Z in this manner, mere human method-beholden science is corrected in the light of superior knowledge.

How is it possible to sustain such a view? Oracular science, like oracular law, may be feasible within delimited subcultures, but it is an impossible luxury within complex societies. There, Averroism secures civil and religious peace; and even if the scientific substance of creationism had not been discredited (as it was, manifestly, during the darwinian revolution), a hearing for such a secretarian epistemology must be sought in vain within the central-societal, cosmopolitan media of communication.

Sociologically, the short answer[12,43,51] is that sectarian Protestantism (aided especially by the segmented social structure of North America) preserved older scholastic philosophy in insulated subcultural enclaves with their own schools, presses and other (peripheral) media of communications. They thus bypassed entirely Averroism and the kantian and darwinian revolutions in the more cosmopolitan media.

Creationists are scholastics . they will produce lists of real truths about nature allegedly anticipated by Biblical writers and only later verified by science.

Scholastic "proto-postivitism"[21] regards the ordinary untutored observer as the unit of knowledge acquisition. Naive empiricism is applied to a naively real world in quest of inductively established certainty; 'proof' is demanded equally of religious and scientific propositions. Thus Arthur Pierson, in *Many Infallible Proofs. The Evidence of Christianity* (1886), could say, "Nothing," either scientific or religious,

"is to be accepted unless based in good evidence," so that if the Bible is read "in a truly impartial and scientific spirit," pious "Thomistic" doubt will dispel infidel doubt[12] Religion is rational, like science; so science is like theology, comprised of certain evident propositions about a real universe, not of more-or-less probable, conventional, theory-laden conjectures.

The same pre-kantian spirit of doxological science, evident in such members of the "parson naturalist" tradition as John Ray, Gilbert White and Jonathan Edwards, and also in the writings of Newton and fellow members of the Royal Society[52,53], continues. It echoes in Paley's memorable *Natural Theology*[54] as well as in forgotten fustian titles[55-60] and their successors[61-63] Its arguments were merely rephrased when Mr Ivan Stonehocker (President, Creation Science Association of Alberta) responded[64] to the claim by the provincial minister of education that the scientific community, not public education, determined the validity of scientific claims

> The scientific community accepts on faith the assumption that the universe and life on earth had a natural beginning There is no evidence or proof for that position — it is simply a philosophy, nothing more Science can only properly deal with events which are observable, repeatable and testable (thus) all discussion of evolution should be turfed out of all courses and all textbooks

Much the same happened when, on US television, creationist the Reverand Mr James Robinson gleefully accused evolutionist Carl Sagan of relying on mere faith in unproven theories Fundamentalism turns out to be some kind of arch-rationalism

Compare Australian creationist Mr A.W Mehlert on punctuated equilibrium: " unless you believe in natural miracles the hard facts (*sic*) of science are in strong disagreement with suggested mechanisms to support the new evolution"[65] Or compare Professor H. Enoch, MA, FZS, retired chairman of the Zoology Department, University of Madras, and now a Vice-President of the Creation Science Movement: "Careful reading of the Scriptures, with an open mind, will reveal that no established scientific fact contradicts the story of creation as described in the first chapter of the Bible"[66].

> there are many men who, though knowing absolutely nothing of the subject with which they are dealing, wish, nevertheless, to damage the author of some view with which they think fit to disagree What they do, then, is not to go and learn something about the subject, (but) wind up saying that: "After all, you know, the principles and methods of this author are totally opposed to the canons of the Baconian philosophy "

Thus, Thomas H Huxley[67] on some of his contemporaries — and some of ours. If scientific knowledge (or selected offending parts of it) cannot be "proven" in a laboratory, or rests on theoretical conjecture, or falls short of inductive certainty from common-sense observation of the facts, then away with it; it is not science. As younger fundamentalists join their contemporaries in mass education, they are exposed to post-nineteenth-century philosophy, and find it just as easy to abuse their opponents with Popperian post-positivism as with Baconian protopositivism[68]

This is not Popperianism, it is Popper-chopping. Popper is chopped in two ways. First, anomalous or difficult data are held to falsify decisively Second, Popper's erstwhile scepticism about Darwinism as a "metaphysical research programme"[69] is invoked. The former, "naive falsificationism"[37], forgets that any theory will be underdetermined by the data available, so that knock-down falsification is quite uncommon. Second, although Popper said "metaphysical", he also circumspectly said "research programme" Popper has, in any case, since retracted this criticism[70,71]. Thus creationist Popper-chopping is (at best) disingenuous[72].

Opportunity structure

Influence abhors a vacuum, and opportunists require 'opportunity structures'[73] So why are creationists so influential? Not through sheer numbers, the movement's core of adherents is small, and its kernel (actual members of scientific creationist organizations) numbers no more than several thousand worldwide. Influence amplifies within an opportunity structure whereby (1) the core uses (2) a protective belt of mainstream intellectuals (willing and unwilling) plus (3) the contemporary climate of public opinion and scientific understanding.

Perhaps the disproportion of physicists and engineers in the creationist movement is no accident physical scientists are professionally disposed to puzzle over central biological concepts.

The protective belt consists of draftees and volunteers. With sufficiently loose standards of argument, the pool of draftees approaches infinity; reading creationists, "one would think that the main spokesman for the fundamentalist cause are Ernst Mayr, G.G. Simpson, Theodosius Dobzhansky and Stephen Jay Gould!"[7] Eldredge and Gould have been drafted (protests[34,74] unheeded) because punctuated equilibrium[75] challenges Darwin's own gradualist view of the tempo and mode of evolution; and whereas doubting Thomism thinks science requires foundational certainty, in principle it cannot distinguish typical intra-scientific dissent from outright repudiation of evolution Thus creationist Mehlert[65]: "Each time the differing evolutionist factions attack each other, all the profit goes to the creationists who can reap the best from both worlds." Likewise, Popper's scepticism is noted, but neither his circumscription nor subsequent retraction

Such a draft is difficult to dodge; some do not try, although there are degrees of volunteering Perhaps the disproportion of physicists and engineers in the creationist movement (and their resurraction of misapplied probability arguments[37,76,77]) is not accidental; physical scientists are professionally disposed to puzzle over central biological concepts (for example, that individuals in a species are not identical in the way that atoms of an element are, that populations and their dynamics, not individuals, are the units of selection; that consequently "in complex, historically formed systems things occur that do not occur in inanimate sytems"[78]) Beyond intra-scientific misunderstanding, lawyer Norman MacBeth[35] mistakes scientific for legal truth-testing. However, the track record of a research programme carries over from case to case (whereas that of contesting lawyers does not); and the analogy, evolution: creationism:. American prosecutorial burden of proof: defendant's presumptive innocence, is unsound.

At what point does confusion pass into wilfulness? Liberal theologian Huston Smith thinks[79] that creationism does public service in policing "the scientific establishment" lest mechanism and reductionism unweave the rainbow. Paul Feyerabend (thoroughly "against method"[80]) proclaims "Three cheers to the fundamentalists in California who succeeded in having a dogmatic formulation of the theory of evolution removed from the textbooks and an account of Genesis included"[81]. (His immediate disclaimer that a creationist establishment would also be dogmatic may strike some as small consolation.) And what of a palaeontologist, the Sorbonne's Pierre Grasse[82], whose nationalist disdain for "daydreaming" across the Channel produces. "The probability of dust carried by the wind reproducing Duerer's "Melancholia" is less infinitesimal than the probability of copy errors in the DNA molecules leading to the formation of the eye ."? Fred Hoyle propagates[83] this same elementary misunderstanding, now a creationist mainstay[84,85]. Likewise the claim that natural selection is tautologous in which Hoyle is joined by palaeontologist Colin Patterson of the British Museum (NH). Creationists take much aid and comfort here. A 1981 talk in which Patterson likened evolutionary theory to religious dogmatism, and said that "evolution not only conveys no knowledge but seems somehow to convey anti-knowledge", was transcribed and circulated (over Patterson's protest[86]) by creationist engineer Mr Luther Sunderland. This is odd, since Patterson also dubs creationism "anti-knowledge"; but he also asserts a baconian view of evidence and theory-testing. On "Proof and Disproof" (*sic*)[87], Patterson commends Darwin's misleading claim that

Fred Hoyle propagates this same elementary misunderstanding, now a creationist mainstay.

he was prepared "to give up any hypothesis ... as soon as the facts are shown to be opposed to it" and warns: "evolutionary theory is not testable in the same way as a theory in physics, or chemistry, or genetics, by experiments designed to falsify it." Finally, there is the matter of transformed cladism (which Patterson[88] champions, along with various recent contributions to *Systematic Zoology*). Its goal of theory-free taxonomy is debateable[89], but its appeal for Doubting Thomists is understandable.

Howbeit willing or unwilling, the protective belt is useful only within a particular climate of scientific understanding. Much ink has been spilt over the rediscovery in recent decades of the insufficiency of reason, and of other curiosities of post-industrial society such as the fact that many people both ride the Clapham omnibus and consult their horoscopes. Yet caution might be urged in interpreting research evidence in favour of pervasive anti-rationalism. For example, one poll taken late in 1981[90] (at the height of the furor) was widely reported as showing that 86 per cent of Americans favoured creationism. What it actually showed was that only 10 per cent believed in creationism, while 76 per cent favoured teaching both creation and evolution. A more recent survey of science students at Ohio State University corroborated, with 80 per cent in favour of both in science courses, although students with increased education in biology were less likely to concur[91]. This suggests that it was not creationism, but belief in fair play (or perhaps the belief that both are "only" theories, and thus on a par) that is at work.

Clearly, the creationists pitch their public appeal to a widespread cultural belief in fair play and equal time for the underdog[11]. And their campaign must attract support, perennially, to the extent that it is able to tap perennial conditions such as "Pluto's Republic" fed by mass education, populist distrust of professional politics in democracies, a folk-epistemology of common-sense empiricism, and simply poor scientific education (of the sort that especially afflicts America, in part because of the erosion of biological curricula by creationism). In other words, the "success" of creationism may be an artifact of the "one-eyed man effect"[92], in which fervently communicated belief fills a vacuum simply in default of any better-defended or better communicated contender. On the other hand, creationism itself is parasitic on the distinctively Western culture of science, including the packed-down science characteristic of modern common-sense knowledge. Thus, not surprisingly, there is some evidence from the counter-mobilization of anti-creationists[93,94] that (*just* because creationism is likely to appeal to those with an interest in and limited knowledge of science) members of the public initially disposed to entertain creationism will change their minds when confronted with a well-argued case for evolution.

Whither creationism?

If the events of 1980-82 appeared as a flash in the pan, the social forces conducive to the creationist movement are perennial. It may disappear from time to time below the threshold of public perception. It has not thereby gone away; though "monkey trials" may not make the headlines, creationists are still at work. Upgrading the climate, and deflating the protective belt, might curtail the disproportionate influence of the movement's core; and, if it does thrive on an outmoded philosophy of science, then including the history, philosophy, and sociology of science as an integral part of science education might exert significant deflationary pressure. Some might regard attention to the climate of "conventional wisdom" as a mere hobby or distraction from real science. However, although the conventional wisdom may be conventional, it may also embody some wisdom and produce some consequences for the support of science; and the scientific community might well ask if concerted attention now is not a small price to pay in order to avoid future generations who, having passed through higher education, agree with that 25 per cent of Ohio State students who believe that evolution is just bunk[91] — "even the scientists say so".

Evolution of tumours and the impact of molecular oncology

George Klein & Eva Klein

Department of Tumor Biology, Karolinska Institute, Box 60 400, S-104 01 Stockholm, Sweden

It is generally accepted that tumours arise through the accumulation of several changes affecting the control of cell growth. Recent advances in molecular biology have made it possible to define some of these changes in molecular terms and to trace the steps by which certain tumours evolve.

FEW would contest the statement that the division and differentiation of somatic cells in higher organisms are regulated by multiple controls. Because cancer develops by the emancipation of a single cell from host controls, it probably arises in several steps. This has been confirmed in a number of ways. Statistical analyses of age-incidence curves have suggested three to four successive mutation-like changes for leukaemias and six to seven for carcinomas (see refs 1, 2 for review). This must be considered the minimum, rather than the actual number, as only the rate-limiting steps will be detected by statistical analysis.

Histological, cytogenetic and experimental analyses have also confirmed that the natural history of spontaneously occurring human and animal cancers is usually a multistep process, based on the successive emergence of new subclones that replace their predecessors as a result of some selective growth advantage[3-5]. The only known exceptions are found in experimental viral oncology. Some of the retrovirus-transduced oncogenes (for example, v-*src*) can cause tumours in a single step. However, as demonstrated recently by Temin[6], serial passage *in vivo* in the laboratory puts the v-*onc* genes carried by the directly transforming RNA tumour viruses under selective pressure. Multiple genetic changes that favour transforming and/or tumorigenic activity can accumulate in a single oncogene. The same principle is illustrated even more dramatically by the discovery of an increasing number of retroviruses carrying two unlinked oncogenes that make different products with complementary transforming effects. The natural process of spontaneous tumour development is quite different. Selection acts on the cell, not on a virus. This favours single changes in multiple genes.

Foulds[3,4] was the first to analyse this process of 'tumour progression'[7]. He emphasized that the neoplastic phenotype is composed of several 'unit characteristics' capable of wide variation and able to reassort independently of each other. Thus, the same phenotypic endpoint can be reached through several alternative pathways[4]. Each progression step may reflect the activation, mutation or loss of different genes. Molecular biology has opened the door towards their definition. At least three major functional groups can be discerned already. The oncogenes represent the first group (for review, see ref. 8). They seem to act dominantly in the sense that they can induce transformation when transferred to cultured cells. The best-known example of this group of genes is the *ras* family, in which a single point mutation can confer tumorigenicity. It is, however, unclear whether mutant *ras* genes act as simple determinants *in vivo*. For example, in tumours from human patients the normal germline *ras* allele is often lost[9].

Moreover, there is evidence for a second group of genes, the 'tumour suppressors' or 'anti-oncogenes', that may have to be deleted or functionally incapacitated before a tumour can arise. The most thoroughly analysed example of such a gene is *rb-1*, both alleles of which are lost in retinoblastoma tumour cells[10-12]. It has been suggested that the rb-*1* gene may have a normal regulatory function, possibly in the induction of an essential step in the terminal differentiation of the tissue[11,13-16]. Some other neoplasms, such as Wilms' tumour, familial renal cell carcinoma, neuroblastoma and small-cell carcinoma of the lung (SCLC), seem similarly to require the loss of both alleles of a single gene. This evidence for recessive anti-oncogenes is consistent with much earlier reports of the suppression of tumorigenic behaviour in hybrids derived from the fusion of malignant with normal cells[17-20]. Cytogenetic analysis of such hybrids and their high malignant segregants suggests the existence of different suppressor genes on different chromosomes[21-24]. There is now evidence that the transforming effect of different retroviral oncogenes can be counteracted by different suppressor genes. Recently, revertants *in vitro* of Kirsten-murine sarcoma virus-transformed fibroblasts have been found to suppress *ras*, *fes* and *src*-transformed partner cells, but not cells transformed by *mos*, *fms* and *sis*, after somatic hybridization[25]. Eventually, the suppressor genes may turn out to be as diverse as the oncogenes, if not more so.

The third group of genes that influence neoplastic behaviour may be designated modulators. They do not on their own transform normal into neoplastic cells, but they modify their spread in the organism. They probably constitute a large and heterogeneous group. For example, metastatic spread may be influenced by the genes of the major histocompatibility complex (MHC)[26-29] and invasiveness by those controlling proteolytic and homing mechanisms[30,31]; cellular resistance to immune rejection[32,33] may also play a part. Here we shall discuss the way in which some cancers may develop by a series of different steps. We have selected cases in which individual steps have been analysed in genetic and/or molecular terms.

Burkitt's lymphoma and mouse plasmacytomas

The Epstein-Barr virus (EBV)-carrying African or high endemic form of Burkitt's lymphoma (BL) provides an interesting example of a human tumour that develops in several steps. The tumours are derived from cells of the B-lymphocyte lineage that is responsible for the production of immunoglobulin. At least three different genetic systems may be involved. The first is of DNA-viral rather than of cellular origin. EBV is a highly transforming agent for human B lymphocytes. Epidemiological evidence has shown that an early EBV infection of African children at a relatively high multiplicity contributes to the causation of the tumour[34]. This is corroborated by the discovery that 97% of African Burkitt lymphomas carry multiple copies of the EBV genome in all their cells[35].

The second genetic system is of cellular origin, activated by chromosomal translocations characteristic of Burkitt lymphomas. With the exception of a single atypical BL-derived line[36], all Burkitt lymphomas so far studied have been found to carry one of three specific translocations. This applies not only to the EBV-carrying African form but also to the sporadic

Table 1 Gene interactions in the development of Burkitt's lymphoma

Oncogene or transforming gene	Documented effect	Hypothetical effect	
		In vitro	*In vivo*
EBV (Three active regions in transformed cells)	B-cell activation and immortalization *in vitro* Activation of BCGF production Synthesis of EBNA and LYDMA	Autocrine stimulation BCGF dependence, also reflected by clumping and low agarose clonability. Limited freezing of maturation; some terminal differentiation does occur or can be induced.	Creates latently infected B cells, dependent on and responsive to B-cell growth factor and susceptible to immune control.
Activated *myc*	Juxtaposition to an immunoglobulin locus by chromosomal translocation leads to constitutive *myc* expression	Ability for BCGF independent growth, with or without maintained responsiveness, also reflected by high agarose clonability and growth in single cell suspension Switched on *myc* drives cell division 'from within'?	Decreased dependence on positive growth signals from the outside Resistance to differentiation induction?
Activated *ras* and/or *Blym*?*	Transformation of NIH 3T3 fibroblasts	Changed growth factor or differentiation factor receptors?	May act in complementary or synergistic fashion with activated *myc*

* Activation of these genes has only been demonstrated in some long-established *in vitro* lines

non-endemic cases that occur all over the world. The translocations act by juxtaposing c-*myc* to one of the three immunoglobulin loci, normally active in B lymphocytes, with the result that the oncogene is constitutively activated (see ref. 37 for review). It is possible that a third oncogene system may be involved as well. it has been reported that NIH 3T3 fibroblasts can be transformed with DNA from BL-derived sequences that are related neither to EBV nor to *myc*. The identity of the transforming DNA is currently controversial. There is some evidence for activation of a *ras* gene and of *Blym*[38,39].

How do these genes interact in generating Burkitt's lymphoma? EBV is a uniquely potent immortalizing agent for human B cells. Three regions of the viral genome (LT-1, 2 and 3) are regularly transcribed in immortalized cells[40] The LT-1 region seems to be necessary for inducing the first activation step that is followed by a chain of events leading to indefinite proliferation in the normal B lymphocyte· an EBV substrain in which the LT-1 region has been deleted cannot activate and immortalize normal lymphocytes[41]. The protein product of LT-1 is a DNA-binding nuclear protein of relative molecular mass 81,000, designated EBNA-2 (refs 42-44). A second nuclear antigen, EBNA-1, which was identified earlier, is encoded by the LT-2 region[45]. Repression of the lytic cycle, a prerequisite for the continuous proliferation of the virally transformed B lymphocyte, may require the interaction of EBNA-1, EBNA-2 and some B-cell specific cellular constituent[46].

Recent experiments of Gordon *et al.*[47] suggest that at least part of the immortalizing effect of EBV on the B lymphocyte results from the activation of an autocrine loop (for a recent review of autocrine activation see ref. 48). Both the EBV-transformed B-cell lines of normal origin (LCL) and the tumorigenic BL lines release B-cell growth factor (BCGF), but although LCLs are dependent on it, BL cells are not. Some BL lines are responsive, but others have lost their responsiveness[49]. The course of events is strongly reminiscent of earlier studies on tumours in hormone-dependent tissues where a 'conditioned tumour', initially dependent on the hormonal imbalance that generated it, later becomes independent of the hormone and eventually unresponsive to it[50].

If EBV is responsible for the immortalization of BL cells, what does the *myc*/immunoglobulin translocation contribute to tumorigenesis? In the typical translocations, the *myc* oncogene breaks at its non-coding 5'-end, or at variable distances upstream of it[51-63]. The coding exons of the gene are transposed to the chromosome containing the immunoglobulin heavy-chain genes, head-to-head with the immunoglobulin gene. In contrast, the variant translocations (those involving the immunoglobulin light-chain genes) break the chromosome below the tail end of the gene[64-66]. In these cases, therefore, c-*myc* remains in its original location with the constant region of the κ or the λ light-chain attached to it, in a head-to-tail orientation. Despite these differences, all three translocations activate *myc* transcription constitutively. The importance of this activation and the intactness of the *myc* protein is stressed by the fact that the coding second and third exons of c-*myc* are always intact, despite the considerable variability of the translocation breakpoint in and around the gene. This variability and the equally large variation in the translocation breakpoints within the immunoglobulin genes also implies that no single enhancer or promoter can be responsible for *myc* activation in all or even most of the tumours. This may suggest that what is important is the active state of the chromatin, rather than single specific sites[63,67].

Early interpretations of the mechanism whereby the c-*myc*/immunoglobulin juxtaposition contributes to the tumorigenic process included claims of abnormally high transcription rates, abnormal transcript size, changed promoter use, mutations[68] and changed translational control. Each claim has been documented for some tumours, either in the BL or in the closely analogous mouse plasmacytoma (MPC) system, but none was found to apply to all or even most of the tumours. Perhaps there are several ways of activating c-*myc*, and no unifying mechanism exists[69]. Alternatively, the crucial event may be more subtle than a relatively crude quantitative or qualitative change. The current concept is *dysregulation*. The idea is that the immunoglobulin-juxtaposed *myc* gene has become subject to *cis* control by the constitutively active immunoglobulin region and must therefore behave as if it were part of the immunoglobulin locus itself. The transcription of the normal *myc* gene is associated with competence for cell division[70,71]: in terminally differentiating cells c-*myc* transcription ceases[72]. Mature plasma cells continue to produce immunoglobulins, however, and an immunoglobulin-juxtaposed *myc* may be similar. This would keep the cells in continuous division.

Although there is no direct evidence for this hypothesis, it is supported by comparative studies on the behaviour of the translocated *myc* gene and its normal allele in MPCs and BLs. It has been found repeatedly in both systems that the translocated gene is highly transcribed whereas its normal counterpart is switched off[73-78]. This is compelling evidence for the differential regulation of the two genes.

The BCGF-independence of the BL-cells may result from the locking of the immunoglobulin-juxtaposed *myc*-gene in a continuously active position. It may act as a 'pacemaker' from

Table 2 Expression of three oncogenes in three different tumours of the B-cell lineage, induced by Abelson virus, with or without mineral oil

Tumour	Inducing agent	Cell type	v-*abl* expression	c-*myb*	c-*myc*	Karyotype
ABLS	Abelson virus	Pre-B	+++	Normal	Normal	Normal diploid
ABPL	Abelson+oil	B?	–	+++ rearranged	Normal	No translocation
ABPC	Abelson+oil	Plasma cell	+++	Normal	+++ rearranged	12;15 or 6;15

(After the data of Mushinski and Potter *et al.*[84,89-92].)

within, prompting the continuous re-entry of the cells into the cycle, thereby obviating the need for exogenously supplied BCGF.

Pending further definition of the third oncogene and clarification of the important question of whether the DNA of tumours *in vivo* has the transforming activity that has been reported in the DNA of established BL lines, it may be noted that transforming *ras* genes with the characteristic point mutation have recently been isolated from certain experimental lymphomas[9,79]. The mutant *ras* gene is believed to transform fibroblasts by inducing anchorage independence; but lymphocytes are inherently anchorage independent, so if mutant *ras* genes do play a part in the aetiology of BLs, it must be by some other mechanism. The attachment of the ras protein to the inner surface of the plasma membrane prompts speculations on membrane rearrangements that may interfere with the normal receptor organization and/or the transmission of growth and differentiation controlling signals.

In the natural history of African BL, EBV-transformation of the target cell is probably the first event[80]. The environmental co-factor, perhaps chronic hyperendemic malaria[81], may act by increasing the size of the target cell population. Because the EBV-infected B cell is longer-lived than its EBV-negative counterpart, it may undergo a larger number of divisions before being eliminated by terminal differentiation or by immunological mechanisms. The probability of all genetic aberrations increases with the number of cell divisions, including the risk of the *myc*/immunoglogulin juxtaposition. Heavy malarial infection may facilitate the development of the lymphoma in a dual capacity: polyclonal B-cell activation and T-cell immunosuppression Table 1 is a schematic summary of our current view of the genesis of BL.

It is instructive to compare the course of events leading to BL with those culminating in the development of a mouse plasmacytoma. Molecular studies have confirmed our original suggestion[82] that MPC and BL carry homologous translocations that involve the activation of the same oncogene by an immunoglobulin locus. The close homology of the translocations in these two tumours is remarkable, because their natural history is very different. MPC originates from mature plasma cells, whereas BL arises from a relatively immature B cell, producing the mainly surface rather than the secreted form of immunoglobulin[83]. The human counterpart of mouse plasmacytoma is multiple myeloma, whereas the mouse equivalent of BL is B-cell lymphoma; these cells do not carry similar translocations. What then could account for their regular appearance in BL and MPC? A possible common denominator in MPC and BL is a long preneoplastic period in which the cells are chronically stimulated. Intraperitoneal granuloma induced by mineral oil is a prerequisite for MPC[84] whose development can be prevented by hydrocortisone which inhibits the formation of the granuloma In BL, a functionally analogous chronic stimulation may be provided by the combination of EBV and chronic hyperendemic malaria.

No virus is known to be involved in the development of MPC and the BCGF-mediated autocrine loop may be missing. Note, however, that the mineral oil-induced MPCs are often not transplantable unless the syngeneic recipients carry an oil granuloma similar to that in the original host. This suggests that constitutive activation of *myc* is not sufficient to produce a fully autonomous neoplasm in a single step. Therefore, it is of interest that several secondary changes have been repeatedly found in some MPCs. They include a 6;10 translocation that leads to the juxtaposition of C-κ and an unknown single-copy gene[85] or the activation of the c-*mos* oncogene by the insertion of an intracisternal A particle[86,87] and a variety of other changes (see ref. 88 for review).

These secondary changes have been found in long-propagated lines of mouse plasmacytomas and may thus reflect changes in the tumour in culture. There is, however, one interesting example of an interaction occurring at the inception of the tumour. The induction of primary plasmacytomas can be facilitated greatly by the parallel administration of Abelson virus and mineral oil.[84]. The latency period is reduced and the frequency of plasmacytomas in the susceptible BALB/c strain increased. Abelson virus carries its own oncogene (v-*abl*). In the resulting tumours, the v-*abl* gene is transcribed at high levels, in parallel with the appearance of the typical 12;15 or the variant 6;15 translocation[89]. The same treatment (combination of Abelson virus and mineral oil) also induced some plasmacytoid lymphosarcomas (ABPL), but they show a different pattern of oncogene activation. Mushinski *et al.*[90-92] have shown that these tumours carry rearranged activated *myb* genes, with a long terminal repeat (LTR) from a murine leukaemia virus inserted at the 5′ end of the oncogene. The LTR seems to be derived from the Moloney helper virus. The v-*abl* oncogene is not usually expressed, nor is there any *myc* activation by translocation in these tumours.

These findings are summarized in Table 2. They are contrasted with the Abelson virus-induced pre-B-cell lymphomas in which v-*abl* is highly transcribed, but with no anomalies of c-*myb* or c-*myc* transcription. These experiments suggest that the transformation of cells in different stages of differentiation in the same lineage is brought about preferentially by different oncogenes. A similar situation may prevail in some of the lymphomas and the leukaemias of the human B-cell series. In Burkitt lymphoma and the closely related B-cell-derived acute lymphatic leukaemia, the *myc* oncogene is activated by its juxtaposition to one of the immunoglobulin loci. In contrast, other B-cell tumours may carry 14q markers generated by the attachment of other chromosome pieces to the IgH region of chromosome 14 (ref. 93). Recently, Croce's group has analysed the relatively common 11;14 and 14,18 translocations at the molecular level. They have identified two new potential oncogenes, designated *bcl-1* and *bcl-2*, derived from chromosomes 11 and 14, respectively [94].

Small-cell lung carcinoma

The recent work of Minna's group has interesting implications for the progression of small-cell or oat-cell carcinoma (SCLC) of the lung[95,96]. SCLC exists in a typical relatively low malignant form and in a highly malignant variant form (v-SCLC). Three types of genetic change are found in this system. Most of all the tumours examined have a deletion in the short arm of chromosome 3. Shortest-region-overlap analysis has localized the consistent change to a small area (3p14). It may be significant that this region coincides with the breakpoint in two translocations associated with renal carcinoma (3;8 and 3;11)[97,98]. It also corresponds to the approximate localization of the *raf* oncogene[99]. The SCLC-associated deletion arises by a somatic

change and is not present in the normal cells of the patient. Although the deletion is visible only in one of the two homologous chromosomes, analysis by restriction-fragment-length polymorphism has revealed a deletion in the other chromosome 3 in the tumour cells of heterozygous patients (J. Minna, personal communication). This is consistent with Knudson's[13] hypothesis that some tumours develop only after the loss of both alleles of a single gene.

Activation of a *ras* oncogene by point mutation is the second type of genetic change in SCLC[100-102]. It is only found in a few cases, however, and its significance is therefore less clear

The third genetic change is the most interesting in the sense that its phenotypic consequences are the easiest to interpret. In ~20% of SCLC tumours, or cell lines derived from them, c-*myc* or N-*myc* is amplified 20–80-fold, with substantially increased transcription. This change is regularly associated with the variant v-SCLC phenotype (ref. 95, J Minna, personal communication). Such variants have increased cloning efficiency, shortened doubling times, decreased expression of differentiation markers and decreased adhesiveness compared with the typical tumour. In the patient, v-SCLC is more metastatic and has a poorer prognosis than the typical form. Occasionally, progression from the typical to the variant form can be observed in the same patient The variant appears as a morphologically different subtype in the original tumour or in one or several metastases.

The amplification of *myc* in SCLC is often associated with the appearance of double minute chromosomes, or homogeneously staining regions that do not necessarily correspond to the original location of the amplified gene and whose locations may vary between tumours. In one case, cells from different metastatic sites in the same patient all had amplifications of the same *myc* gene, but in different arrangements.

These findings strongly suggest that the amplified genes can be very labile and that amplification of either c-*myc* or N-*myc* plays an important and perhaps decisive part in the transition of low malignant SCLC to the highly malignant' variant phenotype. Moreover, the postulated double loss of one gene by deletion and the concurrent amplification of a *myc* gene strengthens the analogy with retinoblastoma in view of the recent demonstration of N-*myc* amplification in the latter system[11]. It may also be noted that Minna's findings suggest, for the first time, a functional analogy between c-*myc* and N-*myc*.

The amplification of *myc* has also been found in other types of tumour, the promyelocytic leukaemia line HL60 being a particularly well-known example[103]. This continuously growing cell line shows an extraordinarily high level of c-*myc* transcription, which, however, can be turned off very rapidly when the cell is induced to differentiate[72]. Amplification of *myc* has also been found in various solid human tumours[104] and in transplanted rat hepatomas[105]. In neuroblastoma, N-*myc* amplification appears in stage III and IV tumours and may be related to tumour progression[106]. Recently, we have found amplification of c-*myc* in a highly malignant plasma cell leukaemia, but not in the less malignant multiple myelomas[107].

It may be more than a curiosity that Bishop's group has detected amplification of c-*myc* in a 25-year old, originally polyoma-induced ascites tumour, SEWA[108]. Double minute chromosomes were first discovered in this tumour[109], they carry amplified c-*myc* sequences.

These divergent examples raise a number of intriguing questions about the roles of the *myc* genes in the oncogenic process and in tumour progression; v-*myc* is the only known virally carried oncogene that can induce tumours in all three major tissues: epithelial, mesenchymal and haemopoetic. similarly, c-*myc* activation by retroviral insertion in the chicken bursal lymphoma[110] and by chromosomal translocation in MPC and BL represent early events in the history of these tumours. By contrast, amplification is usually a late event that occurs during the progression of established tumours.

Transcription of *myc* is switched on when the cell cycle is activated in both lymphocytes and fibroblasts[70,71]. If *myc* plays a key part in this activation it is not surprising that the constitutive activation of the gene by viral or cytogenetic accidents that bring it under the *cis* control of highly active regions may keep the cell continuously in cycle. This could happen in cells of many different types. It may be the first step in the chain of events that lead to tumour development, or a late step that prompts malignant progression of established tumours. This also implies that permanent activation of a *myc* gene ought to change certain non-tumorigenic cell lines that have the appropriate genetic constitution to tumorigenic variants. This has been demonstrated experimentally by Keath *et al.*[111]. Rat fibroblast variants that became tumorigenic after transfection with appropriate *myc* constructs showed none of the usual morphological changes of transformed cells, and did not acquire high agarose clonability, but they did have a diminished requirement for serum. In these cells, the transfected gene was expressed at high levels whereas the normal c-*myc* allele was silent, just as the translocated c-*myc* gene is active and the normal allele silent in MPC and BL.

Progression never reaches an endpoint

The clonal evolution of tumour cell populations proceeds through the sequential selection of variant subpopulations from a common progenitor[5,112-114]. New variants may arise at any time; some of them have a selective growth advantage over earlier forms This process may be accelerated by the genetic instability of tumour cell populations, reflected by the high frequency of mitotic errors and variation of genetic markers This instability may become more pronounced as the neoplasm evolves (see ref. 5 for review).

This process can be particularly clearly seen in the chromosomal evolution of chronic granulomatous leukaemia (GGL) carrying a characteristic chromosomal translocation giving rise to what is known as the Philadelphia (Ph^1) chromosome[115,116] During the early, chronic and relatively benign stage of the disease the precursor pool for the entire granulocyte, erythrocyte- and thrombocyte-forming bone marrow is taken over by a single clone of cells carrying the Ph^1 chromosome[117]. Occasionally, it may involve part of the bone marrow-derived (B) lymphocyte series as well. The Ph^1 ($22q^-$) chromosome arises most frequently by a 9;22 translocation. In a variant minority, the exchange seems to involve chromosome 22 and virtually any other autosome.

When it was first discovered, the significance of the Ph^1 translocation was unknown. More recently however, as with the translocations characteristic of BL, it has become possible to look for an interpretation in terms of oncogene activation. In particular, the c-*abl* oncogene, which is located on the tip of chromosome 9, is regularly transposed to the deleted $22q^-$ chromosome in Ph^1-positive CGL[118,119]. It is particularly significant that this happens not only in the typical 9,22 but also in the variant translocations[120] where the deleted distal arm of chromosome 22 moves to another autosome, not 9. The fact that c-*abl* moves also from 9 to 22 in these cases implies that three chromosomes are involved in the variant translocations The consistency of the *abl* transposition greatly increases the probability that it is significant in tumorigenesis

The molecular analysis of this transposition is still at an early stage. On chromosome 9, the breakpoint is immediately upstream of, or within, the c-*abl* oncogene[121]. On chromosome 22, the breakpoints are clustered within a limited 5–8-kilobase (kb) region, designated *bcr*[122]. Little is known about the level of expression, except the interesting fact that a new 8-kb *abl* RNA transcript can be found in Ph^1 + CGL, whereas the 6- and 7-kb transcripts found in normal haematopoietic cells are absent[123]. The functional significance of the transposed *abl*-carrying $22q^-$ chromosome, rather than the reciprocal $9q^+$ fragment, is supported indirectly by the finding that K562, a CGL-derived, originally Ph^1 + erythroleukaemia line, has amplified the chromosome carrying the transposed *abl* gene and its immediate surroundings, but not the reciprocally translocated *sis*-oncogene, located on chromosome 22 distally of the Ph^1 breakpoint[122]

The appearance of the Ph^1 chromosome is the first clearly definable step in the development of Ph^1+CGL. Therefore, its initial action must occur during the early chronic phase of the disease, which has a median duration of 3 years. It usually precedes a second or acute phase, characterized by decreasing cell maturity and increasing blast proliferation. The transition from the chronic to the acute phase is often accociated with further nonrandom chromosomal changes[124]. The most frequent secondary events are the appearance of a second Ph^1 chromosome, or an additional chromosome 8, or an additional long arm of chromosome 17. Note that the trisomy of the c-*myc*-carrying chromosome 8 is the commonest trisomy in all human haemopoetic disorders, ranging from relatively benign myeloproliferative diseases to acute leukaemia[115]. This may be more than a coincidence, particularly if considered together with the fact that trisomy of chromosome 7 is the commonest chromosomal change in Rous sarcoma virus-induced rat tumours[125] and trisomy of chromosome 15 is the commonest and often single chromosomal anomaly in mouse leukaemia[126–128]. The c-*myc* gene has been localized to chromosome 7 in the rat[129] and to chromosome 15 in the mouse[130].

Immunology of host–tumour relationship

Widely polarized views prevail on the question of immune responses to tumours. At one extreme, they are believed to play a crucial part in protecting the host against neoplastic growth. At the other, they are regarded as virtually non-existent. The unfortunate tradition of considering this important problem in all-or-none terms often prevents a more discriminative analysis.

The probability of efficient immune rejection varies depending on the mode of tumour induction. It should be considered separately for tumours induced by DNA tumour viruses, those resulting from retrovirus insertion near a cellular oncogene, and tumours arising from oncogene activation by spontaneous or induced changes in cellular DNA. We shall consider each case in turn.

(1) Oncogenic DNA viruses carry their own transforming genes. This is why transformed cells of this category provide the best targets for host immune surveillance[131]. The evidence for such surveillance is indirect and can best be seen for man in the case of EBV. The immune mechanisms that normally suppress tumorigenesis by EBV are unknown. But it is clear that tumours develop only in special circumstances, for example in patients with relatively grave combined forms of congenital or acquired immunodeficiency. At least some of the fatal mononucleosis cases may belong in this category. The X-linked lymphoproliferative syndrome[132] arises by the proliferation of EBV-carrying lymphoid cells in patients who lack virtually all T-cell activity, have no natural or interferon-activable killer cells and little or no immunoglobin[133,134]. Organ transplant recipients, who have a more restricted immune defect, also develop EBV-carrying lymphoproliferative lesions[135,136].

An interesting but unresolved question arising in connection with these tumours is whether they carry the chromosomal translocations characteristic of Burkitt lymphomas. Such translocations have now been found in EBV-carrying Burkitt lymphomas arising in patients with acquired immune deficiency syndrome (AIDS)[136]. By contrast with Burkitt's lymphoma, which is typically a disease of childhood, Burkitt lymphomas associated with AIDS arise in adults between 20 and 40. The implication is, therefore, that EBV-positive, translocation carrying 'BL candidate' cells may arise at any time of life, but in normal immunocompetent individuals they will be eliminated by immune rejection. The immunosuppressive factor in the African childhood BLs may be chronic malaria[81]. Although T-cell mediated immune responses have been clearly demonstrated in the case of EBV-carrying BLs[138,139], there is no evidence for any host response against EBV negative BLs that carry the same translocations as the EBV positives, nor do they show the occasional spontaneous regressions or the ready curability by chemotherapy that is characteristic for the EBV-carrying and prognostically more favourable counterparts

Note in this connection that the increase in malignant disease in congenitally or iatrogenically immunosuppressed patients is limited to a small and rather unusual group of tumours, such as lymphomas and other lymphoproliferative diseases, Kaposi's sarcoma, skin papilloma and carcinoma[137,140]. It would not be surprising if most, if not all, of these tumours turned out to be DNA-virus related. EBV has already been found in most of the lymphoproliferative lesions in immunodefectives[133,135–138]. Cytomegalovirus is suspected in Kaposi's sarcoma[141] and papilloma viruses may be partly or fully responsible for the skin tumours[142].

(2) There is increasing evidence for cellular oncogene activation by retroviral promoter or enhancer insertion[110] as a mechanism of tumorigenesis. Its relevance has been demonstrated for a variety of avian and mammalian tumours. Only a small part of the retroviral genome is required for the activation of the adjacent cellular oncogene, and that region contains only the regulatory LTR: it has no coding function. Although DNA encoding some of the viral proteins (*gag* and *env*) may also be present, the proteins are not necessary and may even be disadvantageous for oncogene activation because they provide potential targets for the immunological reponse of the host. Given that the protein-coding regions of the virus may be lost while the transformed phenotype of the cell is maintained, it is not surprising that immune rejection of tumour induced by RNA tumour viruses is unpredictable.

(3) Activation of cellular oncogenes by nonviral mechanisms such as point mutations, DNA rearrangements, gene amplification and chromosomal translocations, is probably the basis for most of the spontaneous tumours. The transforming oncogene products are either normal or only slightly modified cellular proteins. It is difficult to see how they could provide a rejection target for the immune system. It is at least possible that a mutated ras protein with a changed amino acid at position 12 or 61 could be antigenic, but this has not yet been demonstrated.

Thus, it seems that specific immune recognition and rejection of antigenically foreign tumour cells is largely restricted to virally induced tumours, and in particular to those caused by DNA viruses. There is increasing evidence, however, that rejection by specifically sensitized T cells is only one of several effector mechanisms that can counteract neoplastic target cells. Another example is provided by natural cytotoxicity that can play a significant role in protecting the host against the metastatic growth of disseminated tumour cells[143,144]. Natural killer (NK) cells can kill sensitive tumours without having been immunized against specific antigens on the target cell surface. Their action is not restricted to virally or chemically induced neoplasms, although different tumours differ in their NK sensitivity. NK cells may be scavengers that can recognize and eliminate 'displaced' cells that have wandered outside their natural homing boundaries. Cells in which the expression of 'self' markers encoded in the MHC is reduced are particularly sensitive targets[26]. It is intriguing that diminished expression of MHC class I antigens can enable tumour cells to avoid rejection by specifically sensitized MHC-restricted cytotoxic T cells, but increases the probability of their elimination by NK cells. Conversely, there is evidence that an increased expression of MHC antigens in mice may increase metastasis[27–29,145] This, then, is a case in which a quantitative change in a universally occurring cell surface marker can either enhance or inhibit tumour progression.

Future of molecular oncology

In his classical paper on tumour progression[4], Foulds emphasized that most tumours develop by stepwise changes in many independent characteristics. The independent assortment of these characteristics leads to the many individual variations in the biological properties of tumours. Foulds stressed the need for a factorial analysis of the complex tumour phenotype. The advent of modern molecular biology has made such an analysis possible. We are at the threshold of a previously unknown world where oncogenes, antioncogenes and other cellular genes inter-

act within complex regulatory circuits. Thanks to the recombinational accidents of the retroviral lifestyle, we now have access to the dominantly acting oncogenes as an unexpected gift from viral oncology. So far, we have learned much at the level of the DNA sequence, something of transcriptional regulation, and a little of the mechanisms whereby the oncogene products can change cellular behaviour. At least two other worlds of genes, so far less conspicuous, remain unexplored. The suppression of tumorigenicity in hybrids between normal and malignant cells and the regular loss of both alleles of a single gene in the genesis of such tumours as retinoblastoma or Wilms' tumour suggest the existence of other, probably quite heterogeneous gene families, tentatively designated anti-oncogenes or tumour suppressor genes that may counteract the expression of the tumorigenic phenotype. There may be also special safeguards to prevent the inadvertent activation of particularly dangerous oncogenes, as illustrated by the example of c-*mos*[146], which is never transcribed in normal cells and even a low level of transcription seems to be sufficient for neoplastic transformation. A 5′ flanking sequence prevents the downstream activation of the gene in the mouse. The human c-*mos* gene shows an even more drastic change, a gap in the middle that may prevent activation altogether. These and other existing hints indicate that evolution may have fixed a whole variety of protective mechanisms that may *cis*- or *trans*-regulate the expression of activated oncogenes. A third and probably even more widely diversified world of genes is not directly involved in the initiation of neoplastic transformation or in the protection against it, but can nevertheless affect the phenotypic properties of established tumours in a prognostically important way. Proteolytic mechanisms that contribute to invasiveness, changes in 'homing markers' that can influence the neoplastic colonization of distant organs, and changes in the ability of tumour cells to induce or to succumb to an immune response fall into this category.

Large-scale regional units in the depleted upper mantle revealed by an isotope study of the South-West Indian Ridge

Bruno Hamelin & Claude J. Allègre

Laboratoire de Géochimie et Cosmochimie, Institut de Physique du Globe and Département des Sciences de la Terre, 4 Place Jussieu, 75230 Paris Cedex 05, France

Isotope analyses of ocean island basalts have demonstrated the existence of regional geochemical provinces, the Indian Ocean being distinguishable from the North Atlantic and Pacific oceans. Equivalent analyses of basalts from the South-West Indian Ridge now indicate that the upper mantle under the Indian Ocean also has a distinct isotope composition. Thus, the upper mantle itself must be composed of several discrete provinces which may relate to the convection pattern.

INTERPRETATION of isotope variations observed in basalts from mid-ocean ridges (MORB) is used currently to infer the structure of the upper mantle and the processes acting at ridge crests[1-3]. Studies of the Mid-Atlantic Ridge (MAR)[4-8], the East Pacific Rise (EPR)[9] and Juan de Fuca and Gorda ridges[10] have shown that the isotope results for MORB from these three ridges define common linear correlations in the Pb/Pb, Pb/Sr and Sr/Nd diagrams. These 'MORB' alignments are often interpreted as evidence of mixing between two types of mantle sources under the ridges. The first source is convecting asthenospheric material, corresponding to the 'depleted values', less radiogenic for Pb and Sr and more radiogenic for Nd, whereas the second is composed of blobs thought to be the source material of ocean island basalts and is characterized by more radiogenic Pb and Sr and less radiogenic Nd compositions. This model is based partly on the fact that isotope results for islands of the North Atlantic and East Pacific oceans extend the MORB alignments for these oceans in all the diagrams[5,11-13].

The study of the Indian Ocean allows an interesting test of this model, because it has been demonstrated[11,14,15] that Indian Ocean islands have isotope compositions which are not on the extension of the Atlantic and Pacific MORB alignments in the Pb/Sr diagram. Dupré and Allègre[15] have given preliminary results for MORB samples of the Carlsberg Ridge which suggest that such a regional characteristic of the Indian Ocean is also found in ridge products; the present study of the South-West Indian Ridge (SWIR) further documents this.

The SWIR is interesting because two hotspots, the isotope compositions of which have already been determined, are very close to it: Bouvet[11,16], on the south-west extremity, and Marion–Prince Edward (S. R Hart and A. J. Erlank, manuscript in preparation), on the centre of the ridge. Le Roex *et al.*[17] have measured Nd and Sr isotope compositions of samples from the south-west part of the SWIR, whereas we report here the Pb, Sr and Nd isotope results for the north-east part.

Samples

The samples from the SWIR analysed here were collected during the MD34 cruise of the RV *Marion Dufresnes* in February 1983. Eight dredging locations were spaced regularly from the Atlantis fracture zone (57 °E) (at 13° longitude from the Rodriguez triple junction) to the Prince Edward fracture zone (35 °E). The ridge rises continuously from depths of ~4,000 m at the triple junction up to the swelling where the islands of Marion and Prince Edward emerge near the ridge. This bathymetric swelling also corresponds to the convergence of the Madagascar plateau to the north and the Crozet plateau to the south-west (Crozet Island itself being 770 km from the ridge at this point).

The dredges were all performed in the axial valley, clearly identifiable by its magnetic signature. The centre of each ridge section delimited by major fracture zones was chosen for sampling (Fig. 1). The dredge D8 (62 °E) yielded only serpentinites, but in all other cases variable amounts of basaltic glasses were obtained

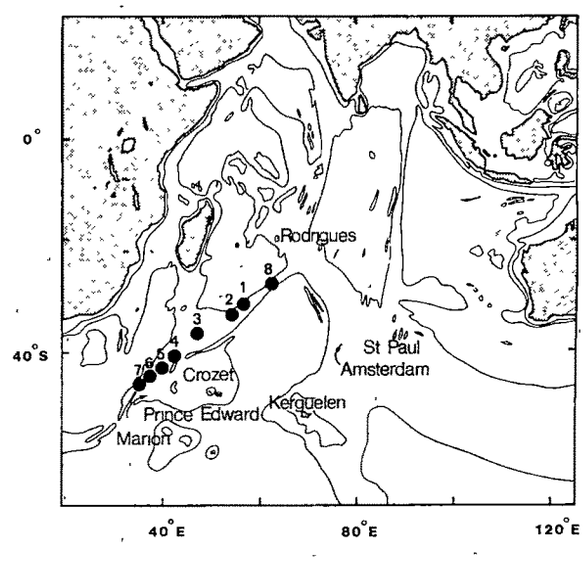

Fig. 1 Bathymetric chart of the Indian Ocean showing the location of the height dredges of the MD34 *Marion Dufresnes* cruise.

Two samples from the MAR have been added to this set of samples, to assess the differences between the two oceans. Both samples are from the Kane fracture zone region, which has given some of the least radiogenic Pb and Sr isotope results[9,18]. One of these samples (AII 96 18-1) had already been analysed for Sr and Nd by Machado *et al.*[18].

Analytical procedures

Between 100 mg and 700 mg of glass was chosen, using a binocular microscope to eliminate any pieces of basalt with visible signs of alteration, encrusted sediments or plagioclase phenocrysts. Pb, Sr and Nd separations were performed using the standard procedures of Manhes *et al.*[19], Birck and Allègre[20] and Richard *et al.*[21]. Powders obtained by crushing millimetre-sized pieces of glass in a boron carbide mortar were leached in 6 M HCl before dissolution, to remove marine Sr contamination.

Pb, Sr and Nd isotope compositions have been determined sometimes on the same powder sample. Pb was first separated in 0.5 M HBr solution after dissolving the powder in HF and HBr; fluoride residues were next eliminated by dissolving in $HClO_4$ and evaporation before Sr and Nd separations. Blank levels and standard calibrations are shown in Table 1.

Table 1 Pb, Sr and Nd isotope data for SWIR glasses

Pb isotope results are calibrated against SRM 981 measurements, with a discrimination factor of 0.1% per mass unit Errors are 1σ uncertainties taking into account the uncertainty of this discrimination correction[9] Pb concentrations have been determined in most cases using a ^{205}Pb spike, and range from 290 to 700 parts per 10^9 (except for the serpentinite D8, 50 parts per 10^9). Sr isotopes are measured with a CAMECA double collector The results are calibrated against the NBS 987 standard, whose measured value is 0 710254±2 (23 measurements) The results are then corrected to the 0.71015 value previously measured with a single collector spectrometer. Errors are 2σ on the mean uncertainties. Duplicates are separate determinations on different glasses from the same dredge. Nd isotopes are measured with double filament technique with H_3PO_4 loading. The results are calibrated against a Johnson Mattey 321 standard, whose measured value is 0.511959±8 (11 runs). Pb blanks are controlled routinely and are always <0.7 ng (the blank correction is then much lower than uncertainties within the run). Sr blanks are <1 ng; Nd blanks are <0.1 ng.

* Pb/Sr/Nd analysis on the same dissolution

† Value from Machado *et al.*[18]: 0.70233±3

Results

Pb/Pb diagrams. As already found for other ridges, the Pb isotope results are correlated positively in both $^{207}Pb/^{204}Pb$ against $^{206}Pb/^{204}Pb$ and $^{208}Pb/^{204}Pb$ against $^{206}Pb/^{204}Pb$ diagrams (Fig. 2). The dredge D5 is an exception and will be discussed later.

The most salient feature of these results is that the least radiogenic extremity of the Pb/Pb correlations of the SWIR is clearly different from that obtained for the Pacific and Atlantic oceans: these values are less radiogenic for $^{206}Pb/^{204}Pb$ (17.5) but comparable for $^{207}Pb/^{204}Pb$ (15.43) and $^{208}Pb/^{204}Pb$ (37.3). This can be verified in Fig. 2 where the isotope domains obtained for other oceans[1,7–9] have been plotted for comparison. The two Atlantic samples analysed during the present study (Table 1) confirm that this distinction is indeed real and cannot result from analytical bias.

At the other extremity of the SWIR Pb/Pb correlations, the values obtained are equivalent to the results for common MORB in the Atlantic and Pacific oceans. As a consequence, the Pb/Pb slopes calculated in both diagrams are lower for the SWIR than for the MAR and EPR. Note that these results are consistent with those of Dupré and Allègre[15] on the Carlsberg Ridge, which plot exactly on the same correlation in the $^{208}Pb/^{204}Pb$ against $^{206}Pb/^{204}Pb$ diagram.

The dredge D5 sample displays a very different lead isotope composition. It has the smallest radiogenic $^{206}Pb/^{204}Pb$ (16.96) so far measured for an oceanic sample, and its $^{207}Pb/^{204}Pb$ (15.49) and $^{208}Pb/^{204}Pb$ (37.31) are distinctly above the MORB Pb/Pb correlations. Such values are exceptional for zero age mantle samples. Samples from islands such as Kerguelen[14], Tristan da Cunha and Gough[11] or from aseismic ridges such as Walvis[22] and Ninety-East[15] also have $^{207}Pb/^{204}Pb$ and $^{208}Pb/^{204}Pb$ ratios above the MORB correlation, but their $^{206}Pb/^{204}Pb$ are more radiogenic than the D5 value.

Finally, the peridotite D8 (not plotted) has a $^{207}Pb/^{204}Pb$ (15.58) slightly higher than the basalts of similar $^{206}Pb/^{204}Pb$ (18.36).

Pb/Sr diagram. The range of $^{87}Sr/^{86}Sr$ variation is from 0.7027 to 0.7030, again with the exception of D5 (0.7047; Fig. 3) These Sr values are higher than those obtained on the EPR and MAR for comparable $^{206}Pb/^{204}Pb$, and again this difference is confirmed by the two new results on Atlantic samples. The data for the SWIR are then above the Pb/Sr correlation discovered by Dupré and Allègre[7] and Cohen *et al*[8] for the Atlantic and confirmed by Hamelin *et al.*[9] for the Pacific. Again, this feature is also found for the Carlsberg samples[8,15,23] and seems to be a regional characteristic of Indian MORB

The unusual dredge D5 is far removed from the usual depleted mantle domain, with a $^{87}Sr/^{86}Sr$ of 0.70472. Again, this value is similar to those obtained on Kerguelen Island[14] or the Walvis Ridge[22].

The peridotite D8 gave a $^{87}Sr/^{86}Sr$ of 0.7071. Such high values, described in ophiolite peridotites[24,25], have been interpreted as evidence of interaction with sea water in oceanic layer 3.

Nd/Sr diagram. As for Sr, the range of Nd variation is restricted (0.51307–0.51291). Note that these results display less variation than those near the Bouvet hotspot of Le Roex *et al.*[17]. The data are in the usual Sr/Nd correlation for MORB. The ε_{Nd} values (5.7–8.8) are lower than those of the most depleted MORB of the Atlantic[8,18] and Pacific[26], and comparable to intermediate

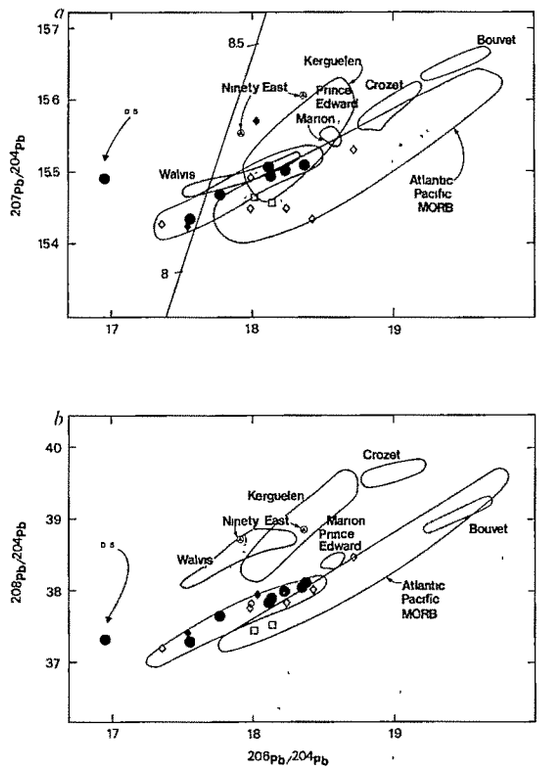

Fig. 2 *a*, Pb/Pb (α, β) diagram; *b*, Pb/Pb (α, γ) diagram ●, SWIR (this study); ◆, SWIR data[15]; ◇, Carlsberg ridge data[15,23]. □, Kane fracture zone (this study). References of the islands and Atlantic and Pacific MORB are given in the text, except for the Crozet field (W M White and B Dupré, unpublished data) The geochron is calculated for an age of the Earth $T_0 = 4.55 \times 10^9$ yr Two values of μ ($^{238}U/^{204}Pb$) are given as reference

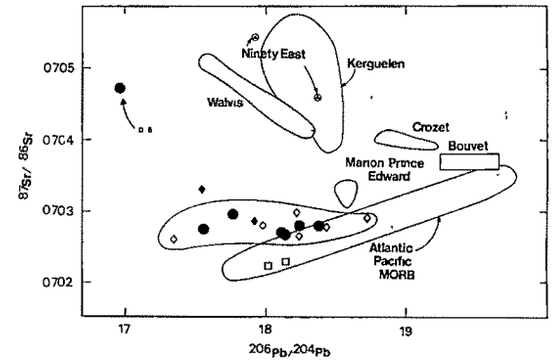

Fig. 3 Pb/Sr diagram. Symbols as described in Fig. 2 legend.

values such as those of the Reykjanes Ridge near Iceland[27] Their Sr/Nd compositions would then seem to be somewhat more 'enriched' than Atlantic MORB whereas the Pb/Pb results are more depleted

The D5 dredge is again exceptional, with a $^{143}Nd/^{144}Nd$ of 0.512448 ($\varepsilon_{No} = -3.3$), comparable with those of Kerguelen[28] or Walvis Ridge[22] samples.

Geographical distribution of the isotope variations. The least radiogenic Pb and Sr values of the SWIR are found on the eastern part of the ridge, which corresponds to the deepest portion and to the triple junction zone. Dupré and Allègre[15] reported a similar nonradiogenic result for a sample dredged at the triple junction.

At the opposite extreme, the more radiogenic values (D6 and D7) correspond to the shallowest part of the ridge, near the Prince Edward and Marion islands, and the isotope values approach those obtained by Hart and Erlank (manuscript in preparation) for basalts from these islands.

Discussion

Present-day source mixing under the SWIR. Isotope variations along ridges are thought to result from mixing between asthenospheric material and blobs of more radiogenic material. This has been well documented near Iceland[4,5], the Azores[6,7,9] and Bouvet[17] Island for the MAR and for the Galapagos spreading centre[30] near the Galapagos archipelago. In all these areas, hotspot influence on the ridges is well known from geochemical and bathymetric evidence[29].

A more complete sampling of the SWIR will be needed to investigate fully the isotope gradient away from Marion and Prince Edward islands, but it is clear that dredges located on the bathymetric swell of the ridge (D6, D7) display Pb and Sr isotope results analogous to those of the islands (S. R. Hart and A. J. Erlank, in preparation) and that these results are thus in agreement with the model of present-day mixing for ridges.

Note that Pb seems to be the most sensitive tracer for this mixing process, because the Nd and Sr ranges of isotope variation remain smaller than for Pb. This suggests a larger difference in isotope composition between the asthenosphere and blob material for Pb than for Nd and Sr.

The question of the identification of the exact isotope composition of the enriched end-member cannot be solved only from isotope arguments, because the results measured on the islands are themselves representative of mixtures between blob and asthenospheric compositions[1,11,30]. For instance, in this geographical area, the isotope difference between Crozet[15] and Marion–Prince Edward (S. R. Hart and A. J. Erlank, in preparation) could be interpreted either as resulting from completely different sources for these blobs or, conversely, as variable proportions of a common blob in the material erupted at the surface. More detailed studies of the Crozet swell are needed to elucidate this question

Origin of the depleted end member. At the other extreme of the SWIR mixing trend, the depleted end member, considered as representative of the asthenosphere, is characterized by particularly nonradiogenic $^{206}Pb/^{204}Pb$ values, but higher $^{207}Pb/^{204}Pb$, $^{208}Pb/^{204}Pb$ and $^{87}Sr/^{86}Sr$ and lower $^{143}Nd/^{144}Nd$ ratios, compared with the lower end-member values of the MAR and EPR. It must be emphasized that, whereas several studies have already suggested some unexpected enrichment of Indian MORB[11,15,31], we present here the first evidence that this difference is indeed a regional characteristic of the most depleted end-member in this ocean.

The present results for the SWIR, the Dupré and Allègre[15] data for the Carlsberg Ridge and our unpublished results on the East Indian Ridge now demonstrate fully that the whole Indian Ocean ridge system displays a characteristic isotope signature. Moreover, analogous Pb/Pb results have been found recently in the Xigaze ophiolites of Tibet[32], which originated in the same geographical area 100-Myr ago. A geographical mapping of isotope compositions has already been discussed for oceanic island results[15,33]. Our results described here demonstrate that similar regional variations also exist for the depleted upper-mantle value. Therefore, we conclude that the upper mantle itself must be divided in different provinces, which are probably related to different convective units. This raises the obvious question of the physical meaning of the different units and of the boundaries between them (for example, subduction planes, continents, transform faults).

Two issues are then to be discussed: first, to determine possible mechanisms for creating such an isotope composition, and second, to evaluate the consequences of such regional isotope units in asthenospheric reservoirs, all within the overall scheme of mantle convection.

Dupré and Allègre[15] have argued that the specific isotope signature of Carlsberg MORB is a further demonstration of mixing between asthenosphere and blobs under ridges, and that the deviation of these samples from the main Atlantic–Pacific

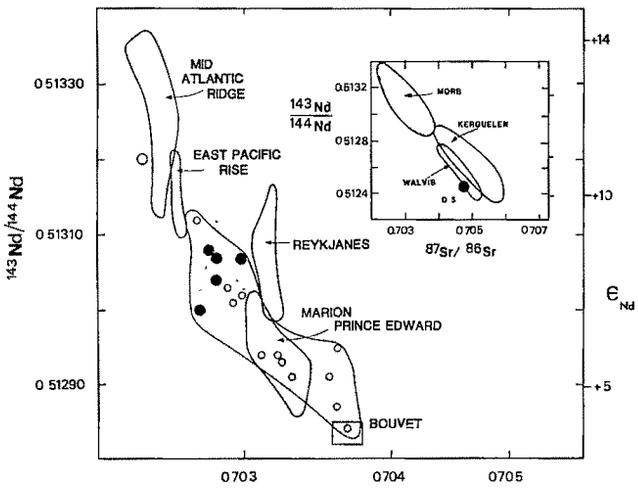

Fig. 4 Sr/Nd diagram. Open circles, data of Le Roex *et al.*[17] for SWIR basalts in the region of Bouvet Island.

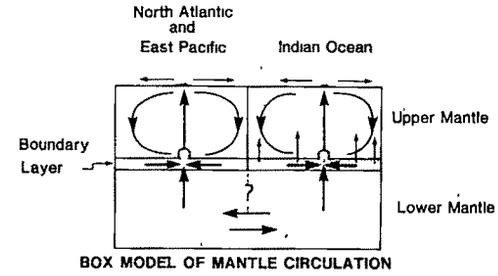

Fig. 5 Possible scheme of mantle dynamics. The upper mantle is divided in different discontinuous boxes, according to the SWIR MORB isotope results. The model where ocean island basalts originate in the boundary layer between upper and lower mantle[38] is illustrated as an example. Since the Indian Ocean island basalt source material (dotted area) is different from other parts of the world, the sub-Indian upper mantle is contaminated specifically by these Indian blobs, some of which reach the surface and others becoming progressively mixed within the upper mantle convection cell.

isotope trend results from the fact that the Indian Ocean islands have isotope characteristics removed from this trend. However, this model cannot explain the isotope composition of the depleted end-member itself, as there is no evidence from available data of any present-day mixing trend between the Atlantic-Pacific depleted end-member and an Indian Ocean island basalt contaminant. At the opposite extreme, the Indian depleted end-member seems to be fairly homogeneous. An additional mechanism, different from the present-day contamination of ridges by blobs discussed in the previous section, must then be proposed. This mechanism could involve a contamination of the whole upper mantle convection cell beneath the Indian Ocean by material with Kerguelen-type isotope values, if enough time has elapsed to allow the isotope homogenization of the contaminated reservoir.

For example, one could first advocate contamination of the upper mantle through reinjection of subducted oceanic lithosphere. The latter is first 'polluted' in accretion zones by blobs with Kerguelen-type signature, then later contaminates the whole upper mantle beneath the Indian Ocean, when it is mixed back after being subducted. This implies that the sub-Indian Ocean mantle has been isolated for several hundred Myr, and, moreover, that subduction-related material has been recycled continuously within the same convection cell. This model then seems unrealistic, especially taking into account the small number of subduction zones in the Indian Ocean. An alternative hypothesis could be that the upper mantle is contaminated by an ocean island basalt reservoir with Kerguelen signature through a 'diffusion-type' process; this contamination operates continuously and uniformly in solid state at depth in the mantle, it allows isotopic homogenization within the upper mantle convection cell, but does not appear any more at the surface as ocean island volcanism, contrary to the present-day occurrence at ridges, for example, near Marion and Prince Edward islands. These different processes can operate simultaneously (Fig. 5); their relative importance depends on the respective scales and rates of mixing, reinjection and homogenization.

The final problem is the interpretation of the unusual values of the D5 dredge. At present, we can speculate using the duplicated analyses of the one sample recovered in that dredge; it will be of great interest to study the lateral extension of this anomaly. Similar results have not been found before on active ridges. On the other hand, the D5 composition is close to the lowest end-member of the Walvis Ridge, as discussed by Richardson *et al.*[22], or to the nonradiogenic lherzolite xenolith from Tanzania analysed by Cohen *et al.*[34]. These results are slightly outside the oceanic mantle array[35] and are not easily interpretable as a mixing between blob-type material and typical depleted mantle values. Possible involvement in the genesis of these structures of material with continental isotope characteristics, through reinjection of sediments[36], continental lithosphere reassimilation[34,37] or percolation of metasomatizing fluids[22] should then be considered.

The MD34 cruise was organized with the efficient cooperation of the French Austral and Antarctic Territories. We thank the RV *Marion Dufresnes* crew for help during the mission. We also thank the scientific team and its chief scientist Ph. Patriat for their active collaboration in ridge exploration and sampling, B. Dupré for stimulating discussions, J. Patchett for comments and S. Richardson for help in preparation of the manuscript. This work was supported by the CNRS ATP 'Géologie-Géophysique des océans'. IPGP contribution 795.

A short conserved sequence is involved in the light-inducibility of a gene encoding ribulose 1,5-bisphosphate carboxylase small subunit of pea

Giorgio Morelli*, Ferenc Nagy*, Robert T. Fraley†, Stephen G. Rogers† & Nam-Hai Chua*

† Monsanto Company, 800 N. Lindbergh Boulevard, St Louis, Missouri 63167, USA

Light induction of chloroplast maturation in plant seedlings ('greening') is associated with the induction in expression of the enzyme ribulose 1,5-bisphosphate carboxylase. To define the regions of a gene encoding the small subunit of ribulose 1,5-bisphosphate carboxylase involved in light inducibility of pea plants, we have introduced derivatives of the gene into petunia cells using a tumour-inducing plasmid vector. A conserved 33-base pair sequence close to the 'TATA' box of the gene is sufficient to confer light inducibility of the small subunit gene.

LIGHT has profound morphogenetic effects on chloroplast development. Seedlings germinated in the dark are arrested in plastid development at the etioplast stage that can then be converted to chloroplasts on illumination. During etioplast–chloroplast transformation there is a rapid synthesis of chlorophylls and a dramatic increase in thylakoid membrane polypeptides and stromal proteins[1]. Although the molecular mechanisms by which these biosynthetic events are turned on by light are still unknown, an important regulatory stage is probably the transcription control of genes encoding chloroplast proteins.

The most abundant protein that increases in concentration during greening is the stromal enzyme ribulose 1,5-bisphosphate carboxylase/oxygenase. This enzyme complex, which accounts for ≤50% of soluble protein in plants, is composed of eight copies each of two non-identical subunits[2]. The large subunit (rbcL) is encoded in the chloroplast[3], whereas the small subunit (rbcS) is encoded in the nucleus by a small multigene family[4–8]. In peas, the amount of rbcS polypeptide in green leaves is 100 times that in etiolated leaves. The increase in rbcS polypeptide during greening is followed by a concomitant increase in the steady-state messenger RNA level[9–11] so that in fully greened leaves, the *rbcS* transcript becomes the most abundant mRNA in mesophyll cells[12]. The light-stimulated increase in *rbcS* mRNA level in peas, as well as other higher plants, has been shown to be mediated by phytochrome[13–15] There is evidence that the control of *rbcS* gene expression by light[16] or phytochrome[17] is at the transcriptional level.

We are interested in defining the molecular events surrounding light-regulated expression of plant nuclear genes. For our investigations we have selected one member (*rbcS-E9*) of the pea *rbcS* gene family as a model system, because the nucleotide sequence of this gene is known and its expression in different tissues of green and etiolated pea plants has been well characterized[11]. Our first objective is to define DNA sequence elements needed for its light/dark regulation and efficient transcription. Previously, we transferred the pea *rbcS-E9* gene into petunia via a tumour-inducing (Ti)-mediated gene transfer vector[18] and demonstrated that this gene is transcribed accurately using its own promoter[19]. Moreover, the *rbcS-E9* mRNA level is regulated by light in petunia calli as it is in pea leaves. These results provide evidence that the petunia expression system can be used to characterize the control sequences of the *rbcS-E9* gene. Our confidence in the fidelity of heterologous expression systems is reinforced by the finding that the 5′ flanking region of another pea *rbcS* gene (*ss3.6*) also shows light-regulated expression after transfer into green tobacco calli[20].

Here we have examined the expression of 5′ deletion mutants of *rbcS-E9* and chimaeric genes in petunia calli We have identified an upstream region needed for maximal expression and delimited a light-responsive sequence to a 33-base pair (bp) region around the TATA box.

Internal deletion and 5′ mutants

With a few exceptions[21,22], most of the animal genes transcribed by RNA polymerase II contain regulatory elements upstream of their transcription start sites[23]. Therefore, we investigated first the role of 5′ upsteam sequences in the regulation of *rbcS-E9* gene expression. Previously[19], we demonstrated that a *rbcS-E9* gene (*rbcS-E9 5′Δ-1052*) containing 1,052 bp of 5′ upstream sequence was transcribed accurately in petunia calli in a light-regulated manner. This gene, therefore, was chosen as the wild type and from this a series of 5′ deletion mutants were constructed by *Bal*31 nuclease digestion (Fig. 1). The deletion mutants were first screened by gel electrophoresis and those in the desired size range were characterized further by sequence analysis to determine their end points. A total of seven 5′ deletion mutants with end points at strategic locations in the 5′ region were chosen for the present study. The first mutant (*rbcS-E9 5′Δ-437*) contains a deletion of ~600 bp; the next three (*rbcS-E9 5′Δ-352*; *rbcS-E9 5′Δ-255*; *rbcS-E9 5′Δ-96*) have end points spaced ~100 bp apart; the next (*rbcS-E9 5′Δ-87*) has its end point just 5′ of the CAAT box; one (*rbcS-E9 Δ-35*) has its end point between the CAAT box and the TATA box, and the remaining mutant (*rbcS-E9 5′Δ-13*) contains neither the CAAT box nor the TATA box and retains only 13 bp upstream of the transcription start site. In addition, we have exploited two convenient *Bst*XI sites flanking the CAAT box to construct a mutant with an internal deletion of 51 bp from −107 to −56.

The internal deletion mutant (*rbcS-E9 5′Δ-107/-56*) and the 5′ deletion mutants were transferred into petunia cells via the Ti-plasmid of *Agrobacterium tumefaciens*, using the pMON145 vector for plant gene transfer. This vector contains the nopaline synthase (*nos*)-neomycin phosphotransferase (*npt*)-II chimaeric gene that confers resistance to kanamycin[18]. Transformed calli were selected and maintained on hormone-free medium containing kanamycin (100 μg ml^{-1}) in continuous light or kept in complete darkness for 5 days before RNA extraction and analysis. To eliminate any possible variations in the physiological state of the calli or in the purity of poly(A)$^+$ RNA among samples, we have used the level of the *npt*-II mRNA transcribed from the *nos* promoter as an internal standard. The use of an internal control also enabled us to reduce the variation resulting from different copy numbers of integrated tumour(T)-DNA, which contained the two genes (*rbcS-E9* and *nos–npt*-II) linked together. Furthermore, calli from different transformation events were pooled to minimize any possible position effects on expression. Transcriptional activities of the mutants were

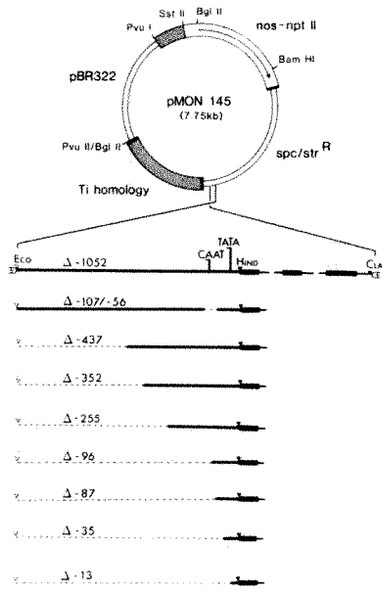

Fig. 1 Construction of *rbcS-E9* deletion mutants. The pea *rbcS-E9* gene is encoded by a 2.4-kb *Eco*RI/*Cla*I fragment that has 1,052 bp of DNA sequence upstream from the transcriptional start site[11]. This fragment was cloned between the *Eco*RI and *Cla*I site of pBR325 to give the parental plasmid, pE9. (A restriction map of the 2.4-kb *Eco*RI/*Cla*I fragment is shown in Fig. 3.) To generate 5′ deletion mutants, pE9 was linearized at the unique *Eco*RI site and digested with *Bal*31 (ref. 36); the digested DNA molecules were ligated to *Eco*RI linkers (CGGAATTCCG; New England Biolabs), treated with *Eco*RI and then recircularized by T_4 ligase. The resulting series of 5′ deletion mutants was analysed by agarose gel electrophoresis to determine the extent of deletion and selected mutants were further characterized by sequence analysis according to Maxam and Gilbert[37]. Mutants with end points at −437, −352, −255, −96, −87, −35 and −13 were selected for subsequent experiments. To generate the internal deletion mutants (*5′Δ-107/-56*), pE9 was digested with *Bst*XI (CAANNNNNNTTG), which cuts the promoter region of the *rbcS-E9* gene at −56 and −107 (ref. 11). The staggered ends of the deleted plasmids were repaired with T_4 DNA polymerase and the DNA was then recircularized by T_4 DNA ligase. The promoter fragment (*Eco*RI/*Hin*dIII) of the internal deletion mutant (*rbcS 5′Δ-107/-56*) was subcloned with the *Eco*RI and *Hin*dIII sites of M13 mp8 and the break points determined by dideoxy sequence analysis[38]. The parental gene pE9(*5′Δ-1052*), the 5′ deleted mutants (*5′Δ-437*, and so on) and the internal deletion mutants (*5′Δ-107/-56*) were subcloned into the unique *Eco*RI and *Cla*I restriction sites of the intermediate vector, pMON145 (ref. 19). The intermediate vector and its derivatives containing the different *rbcS-E9* deletion mutants in *Escherichia coli* (LE392) were mobilized into an octopine strain of *A. tumefaciens* (GV3111) by triparental mating and the co-integrates selected according to Fraley *et al.*[18].

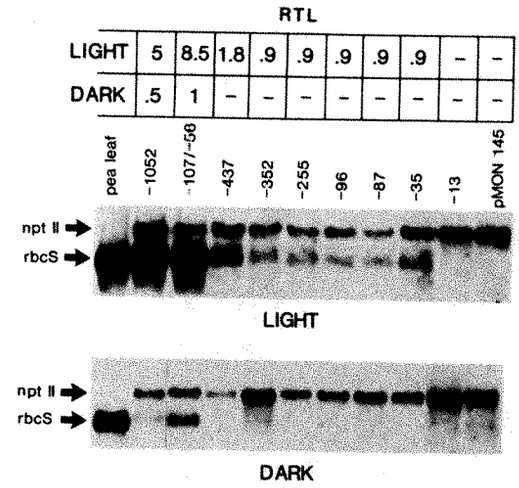

Fig. 2 Northern blot analysis of deletion mutants. The extreme right lane contains 1 μg poly(A)$^+$ RNA from pMON145 calli, whereas the extreme left lane contains 60 ng poly(A)$^+$ RNA from pea leaves. The remaining lanes, indicated by numbers, contain 1 μg poly(A)$^+$ RNA from each of the deletion mutants. The relative transcript level (RTL) refers to the ratio of the *rbcS-E9* transcript to the *nos-npt*-II transcript (upper panel).
Methods. Petunia cells were transformed with *A. tumefaciens* by co-cultivation[18]. Calli obtained from transformation with the pMON145 vector alone or the vector containing the various deletion mutants were propagated on 1% agar plates containing Murashige and Skoog medium and 100 μg ml^{-1} kanamycin[19]. Tissues were maintained in continuous light or transferred to total darkness for 5 days before collecting. Total RNA was isolated with guanidinium thiocyanate as a protein denaturant[39] and poly(A)$^+$ RNA was purified by chromatography on poly(U)-Sepharose[40]. Aliquots of RNA were denatured in glyoxal at 50 °C[41], electrophoresed on 1% agarose gels and transferred onto nitrocellulose filters[42]. Filters were hybridized to ^{32}P-labelled probes containing the coding sequence of the *nos-npt*-II chimaeric gene and of the *rbcS-E9* gene using the hybridization and washing conditions described previously[11,19]. Radioactive bands on Northern blots were visualized by autoradiography and quantified according to Suissa[43].

assessed by their relative transcript level, which is the ratio of *rbcS-E9* mRNA to the *nos-npt*-II mRNA. Poly(A)$^+$ RNAs from pea leaves and from pMON145 calli were analysed along with the mutant samples to localize the positions of the *nos-npt*-II and pea *rbcS-E9* transcripts.

Figure 2 shows that in the hybridization and washing conditions used, poly(A)$^+$ RNA from the gene transfer vector, pMON145, gives only one radioactive band on Northern blots, corresponding in size to the *nos-npt*-II transcript. No cross-hybridization of the pea *rbcS-E9* probe to the petunia *rbcS* mRNA, which is identical in size to the *rbcS-E9* mRNA, was detected. In agreement with previous results[19], we found that the wild-type construct (*rbc-E9 5′ Δ-1052*) produces about five times as much *rbcS-E9* mRNA compared with *nos-npt*-II mRNA (Fig. 2). Deletion of 615 bp from the 5′ upstream region of *rbcS-E9 5′ Δ-1052* decreases the relative transcript level by about three times (mutant *rbcS-E9 5′ Δ-437*) and an additional deletion of 85 bp reduces the relative transcript level further by about twofold (mutant *rbcS-E9 5′ Δ-352*). Sequences between −352 and −35, which include the CCAAT box, have little effect on the relative transcript level, whereas no *rbcS-E9* mRNA was detected in the mutant *rbcS-E9 5′ Δ-13* that has the entire 5′ upstream region, including the TATA box, deleted. From these results, three conclusions can be drawn: (1) a 700-bp sequence between −1,052 and −352 of the *rbcS-E9* upstream region modulates the relative transcript level about six times; (2) The CAAT box centred around −85 does not change the level; and (3) The TATA box is needed for transcritpion of the *rbcS-E9* gene.

To collect further evidence on the function of the CAAT box, we made use of two convenient *Bst*XI sites to generate a mutant (*rbcS-E9 5′ Δ-107/-56*) with an internal deletion from −107 to −56. The deleted segment contains the CAAT box with ~50 bp of surrounding sequences. Figure 2 (upper panel) shows that the mutant *rbcS-E9 5′Δ-107/-56* is expressed in light-grown calli with a relative transcript level of about twice that of the wild type. This result provides unequivocal evidence that the CAAT box is not required for the expression of the *rbcS-E9* gene in petunia calli.

In an attempt to localize DNA sequences required for light-regulated expression of the *rbcS-E9* gene, transformed petunia calli carrying the different deletion mutants were transferred to the dark for 5 days before their RNAs were extracted for Northern blot analysis. The wild-type construct produces a reduced level of *rbcS-E9* mRNA in the dark compared with the light (Fig. 2, lower panel), confirming previous observations[19]. We

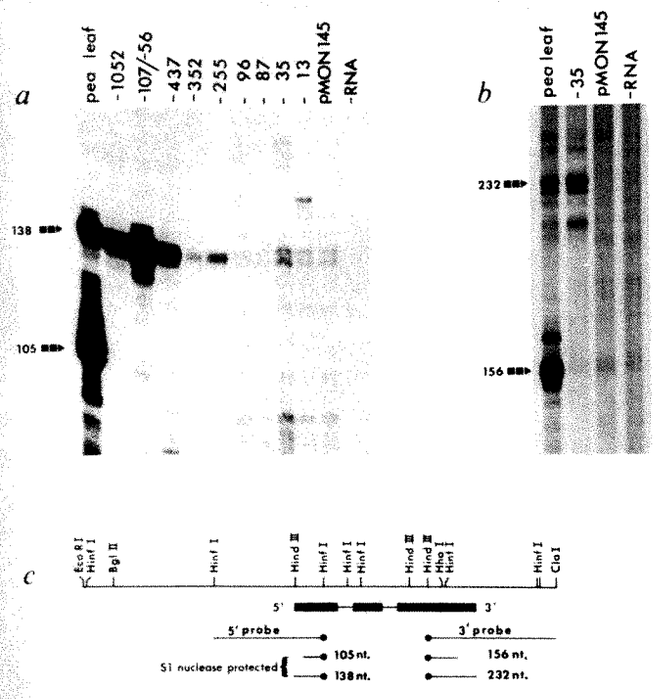

Fig. 3 S_1 nuclease protection assays of pea *rbcS* transcripts from the deletion mutants. Poly(A)$^+$ RNAs from both pea leaf and the deletion mutants were probed with the 541-nucleotide *Hin*fI/*Hin*fI fragment (5′ probe; *c*, left) or with the 690-nucleotide *Hin*dIII/*Cla*I (3′ probe; *c*, right). *a*, Pea-leaf poly(A)$^+$ RNA, 60 ng; poly(A)$^+$ RNA from *rbcS-E9 5′Δ-1052*, 40 ng; poly(A)$^+$ RNA from the other deletion mutants, 1 μg. Arrow 138 indicates the end and the length of the 5′ protected fragment. *b*, Pea-leaf poly(A) RNA, 60 ng; *rbcS-E9 5′Δ-35* poly(A)$^+$RNA, 10 μg; pMON145 poly(A)$^+$ RNA, 10 μg. Arrow 232 indicates the end and the length of the 3′ protected fragment. Pea-leaf RNAs give two additional S_1 signals at the 5′ (*a*, arrow 105) and 3′ (*b*, arrow 156) ends. These result from limited hybridization of other pea *rbcS* transcripts to the probe[11,19].

Methods. S_1 nuclease protection assays were performed according to Berk and Sharp[44] as modified by Weaver and Weissman[45]. The 5′ probe is the 541-nucleotide *Hin*fI/*Hin*fI fragment, whereas the 3′ probe is the 690-nucleotide *Hin*dIII/*Cla*I fragment (lower panel). The ^{32}P-DNA fragment labelled at either their 5′ or 3′ ends were denatured and the dissociated strands separated by polyacrylamide gel electrophoresis. The isolated strands were hybridized with poly(A)$^+$ mRNA in 10 μl of a solution containing 50% formamide, 0.4 NaCl, 2 mM EDTA and 20 mM PIPES (*p*H 6.8) for 12 h at 42 °C. After hybridization, the reaction mixture was diluted to 300 μl with a solution containing 0.3 M NaCl, 30 mM NaOAc (*p*H 4.6), 1 mM $ZnSO_4$, 20 μg ml^{-1} denatured salmon sperm DNA, 300 U ml^{-1} S_1 nuclease and incubated at 37 °C for 45 min. DNA fragments protected from S_1 nuclease digestion were sized on 6% sequencing gels and visualized by autoradiography.

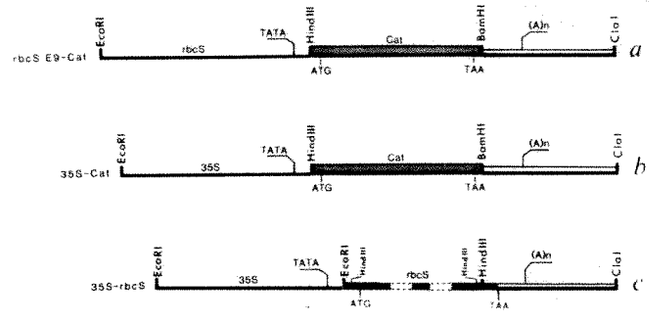

Fig. 4 Construction of chimaeric genes. *a*, *rbcS-E9-cat.* The *Hin*dIII/*Sau*3A fragment coding for CAT in pSV2-cat(24) was subcloned into the *Hin*dIII/*Bam*HI sites of pUC12 to give pUC-cat. The 699-bp *Hin*dIII/*Hin*dIII fragment containing the 3′ end of *rbcS-E9* (ref. 11) was then subcloned into the *Bam*HI site of pUC-cat giving pUC-cat 3′ rbcS. The *rbcS-E9* gene was subcloned in between the *Eco*RI and *Cla*I site of a *Hin*dIII minus a derivative of pMON145 (*rbcS-E9 5′ Δ-1052). The rbcS-E9* coding sequence from *Hin*dIII (−2) to *Cla*I (+1,349) was replaced by the 1,549-bp *Hin*dIII/*Cla*I fragment from pUC-cat 3′ rbcS. The resulting chimaeric genes were designated *rbcS-E9-cat.* The 1,052-bp *Eco*RI/*Hin*dIII fragment of *rbcS-E9-cat*, containing the *rbcS-E9* 5′ flanking sequence, was replaced by a 950-bp *Eco*RI/*Hin*dIII fragment containing the 35S promoter of CaMV[25]. *c*, ^{35}S-promoter-*rbcS.* The 950-bp *Eco*RI/*Hin*dIII containing the 35S promoter was cloned into the unique *Eco*RI site of *rcbS-E9 5′ Δ-13*, using *Eco*RI linkers. The thick line between *Hin*dIII and *Bam*HI indicates the *cat* coding sequence (*a*, *b*). The white line between *Bam*HI and *Cla*I (*a*, *b*) or *Hin*dIII/*Cla*I (*c*) indicates the 3′ end of *rbcS-E9.* The marked line between *Eco*RI and *Hin*dIII indicates the *rbcS* coding sequence.

estimated that the relative transcript level of the dark sample is ~0.5, giving a light-induction factor of ~10 for the *rbcS-E9* mRNA. None of the 5′ deletion mutants (*rbcS-E9 5′Δ-437, Δ-352, Δ-255, Δ-96, Δ-87* and *Δ-35*) active in the light produce detectable amounts of *rbcS-E9* mRNA in the dark. The extremely low level of *rbcS-E9* mRNA in the dark has prevented the estimation of the light-induction factor for the deletion mutants. Nevertheless, it is clear from our results that the mutant, which contains only 35 bp of sequences 5′ to the transcription start site, is still capable of light-regulated expression.

The internal deletion mutant (*rbcS-E9 5′Δ-107/-56*) produces a higher level of *rbcS-E9* mRNA in the dark compared with the wild type (Fig. 1, lower panel), with a dark relative transcript level ~1. Because this mutant is also more active in the light, its light-induction factor is about the same as that of wild type. The light-regulated expression of this mutant provides direct evidence that the 5′ sequence region from −107 to −56, including the CAAT box, is not required for light responsiveness of the *rbcS-E9* gene.

5′ and 3′ S_1 analyses

We have reported previously that a *rbcS-E9* gene containing 1,052 bp of 5′ upstream sequence is transcribed with the correct start site in petunia calli[19]. To examine the effects of upstream sequences on transcriptional initiation, we subjected poly(A)$^+$ RNAs from the different deletion mutants to 5′ S_1 nuclease protection assays. Figure 3*a* shows that pea leaf poly(A)$^+$ RNA gives two S_1-protected fragments, using a probe that covers the 5′ end of *rbcS-E9.* The longer fragment is produced by hybridization of the *rbcS-E9* probe with its cognate mRNA, whereas the shorter fragment is the result of hybridization by other pea *rbcS* transcripts that show sequence homology to the probe up to the first AUG[11]. Consistent with this interpretation, RNA from petunia calli transformed with *rcbS-E9 5′Δ-1052* gives only the longer fragment, indicating that the correct transcription start site is used. Deletion of the 5′ upstream sequence from −1,052 to −255 does not change the S_1 start site. We were unable to obtain reproducible S_1 signals for the remaining 5′ deletion mutants because of the low amount of *rbcS-E9* mRNA, but an internal deletion between −107 to −56 also has no effect. Taken together, these results demonstrate that the sequence elements surrounding the CAAT box as well as DNA sequences upstream of −255 do not affect the accuracy of transcriptional initiation.

The polyadenylation site of the pea *rbcS-E9* gene has been mapped previously to 150 bp downstream from the termination codon[11]. To see whether the same site on the *rbcS-E9* gene of pea is also recognized in petunia calli, poly(A)$^+$ RNAs from *rcbS-E9 5′Δ-35* were subjected to S_1 analysis using a probe that covers the 3′ region of *rbcS-E9.* Figure 3 shows that identical polyadenylation sites are used in petunia and pea, indicating conservation of this processing signal in both plant species.

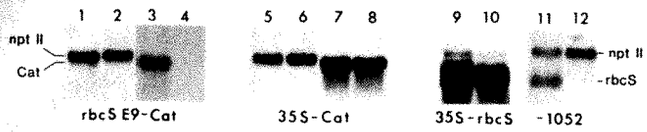

Fig. 5 Northern blot analysis of chimaeric genes. All lanes contain 1 μg poly(A)$^+$ RNA from: *rbcS-E9-cat* light-grown (lanes 1, 3) and dark-grown calli (lanes 2, 4); from 35S promoter-*cat* light-grown (lanes 5, 7) and dark-grown calli (lanes 6, 8); from 35S promoter-*rbcS* light-grown (lane 9) and dark-grown calli (lane 10); from *rbcS-E9 5′ Δ-1052* light-grown (lane 11) and dark-grown calli (lane 12). The filters were hybridized to the following ^{32}P-nick translated probe: *npt*-II coding sequence (lanes 1, 2, 5, 6); *cat* coding sequence (lanes 3, 4, 7, 8); *npt*-II coding sequence plus 3′ end of *rbcS-E9* (lanes 9–12). (Conditions for transformation and growth of the transformed calli and isolation and analysis of the RNAs are described in Fig. 2.)

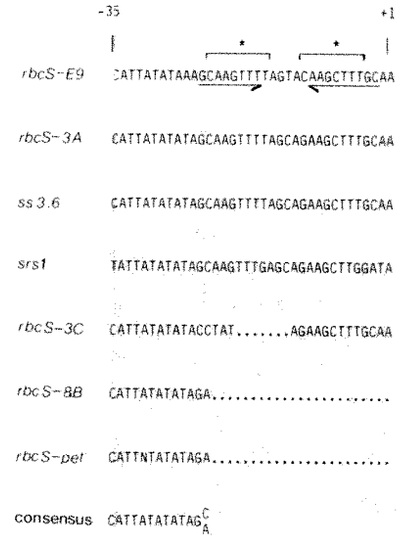

Fig. 6 Comparison of sequences between the TATA box and the transcriptional start site of several *rcbS* genes. Dicotyledonous gene sequences were obtained from the following authors: *Pisum sativum rbcS-E9*[11]; *P. sativum rbcS-3A* (P. Moses, personal communication); *P. sativum ss3.6*[46]; *Glycine max srs1 max*[4]; *P. sativum rbcS-3C* (P. Moses, personal communication); *Nicotiana plumbaginifolia rbcS-8B* (C. Poulsen, personal communication); *Petunia hybrida rbcS-pet* (Monsanto Company, personal communication). Parentheses, direct repeats found in *rbcS-E9*; asterisks, mismatch in the repeat; arrows underline the imperfect palindromic sequence. Sequence downstream of the *rbcS-3C* TATA box are aligned with those of *rbcS-E9* to maximize homology. Similar sequences are not shown for *rbcS-8B* and *rbcS-pet* because of the lack of obvious homology. A consensus sequence derived from the TATA box for the various *rbcS* genes is given.

Expression of chimaeric genes

Our results with the 5′ deletion mutants have allowed us to place the 5′ boundary of the light-responsive sequence of *rbcS-E9* at −35. To determine the 3′ limit of this sequence, we used a convenient *Hin*dIII site near the S_1 start site of *rbcS-E9*. An *Eco*RI/*Hin*dIII fragment containing the 5′ region (from −1,052 to −2) of *rbcS-E9* was fused to the coding sequence of bacterial chloramphenicol acetyltransferase (*cat*)[24] followed by the 3′ polyadenylation sequence of *rbcS-E9* (Fig. 4). We found that this chimaeric gene is expressed in petunia calli; moreover, its activity is regulated by light (Fig. 5, lanes 3, 4). Control experiments showed that the *nos-npt*-II mRNA is expressed equally in the light and dark (Fig. 5, lanes 1, 2). The light/dark regulation of the *cat* mRNA is abolished when the *rbcS-E9* promoter fragment is replaced with a 35S promoter fragment (from −941 to +9) of cauliflower mosaic virus (CaMV) (Fig. 5, lanes 7, 8), which is known to be expressed constitutively[25]. Because the second chimaeric gene contains the 3′ polyadenylation sequence of *rbcS-E9* (Fig. 4), these results indicate that the sequence, by itself, does not have a direct role in light response. In addition, the results also establish that the 5′ upstream sequence of *rbcS-E9*, from −1,052 to −2, is sufficient to confer light-regulated transcription, thus placing the 3′ boundary of the light-responsive sequence at position −2. Our results with the *rbcS-E9* promoter fragment are in agreement with the previous report of Herrera-Estrella *et al.*[20] who used a similar 5′ flanking fragment of another pea *rbcS* gene (*ss3.6*).

In the experiments described above, the *npt*-II and the *cat* mRNA could not be resolved on the same Northern blot because of their size similarity. Therefore, the two transcripts were probed separately. The *npt*-II hybridization signal was obtained after 24 h exposure of the X-ray film (Fig. 5, lanes 1, 2) whereas that for the *cat* mRNA required an exposure time of 7 days (Fig. 5, lanes 3, 4). These results, compared with those in Fig. 2, strongly suggest that the *cat* mRNA level is much lower than that for the *rbcS-E9* mRNA when driven by the same promoter of *rbcS-E9*. The poor expression of the *rbcS-E9* 5′ flanking sequence when joined to a heterologous coding sequence suggests a role for the *rbcS-E9* intragenic region in transcription.

Although we have shown that the *rbcS-E9* 5′ flanking sequence (−1,052 to −2) of pea is able to drive the light-regulated transcription of a test gene, it is possible that differential stability of the *rbcS-E9* mRNA may also contribute to the observed differences in *rbcS-E9* mRNA accumulation in the light and dark. To examine this possibility we used the CaMV 35S promoter fragment[24] to drive the expression of the *rbcS-E9* coding sequence. Figure 5 (lanes 9, 10) shows that the CaMV 35S promoter-*rbcS* hybrid gene is expressed equally in the light and dark, as is the case with *nos-npt*-II, which has been shown previously to be expressed constitutively[25]. Control experiments confirm the expected difference in the *rbcS-E9* mRNA levels between light and dark when the coding sequence is driven by its cognate promoter (Fig. 5, lanes 11, 12). These results provide strong evidence that light has no effect on the *rbcS-E9* transcript processing or mRNA stability. The light-regulated expression of the *rbcS-E9* gene and its mutant derivatives in pea, therefore, mainly reflect control at the transcriptional level.

The experiments described above provide information on the relative strength of the CaMV 35S promoter and the *rbcS-E9* promoter. In these experiments, the Northern blots were hybridized with a probe containing a 1.2-kilobase (kb) coding sequence of *npt*-II joined to a 0.69-kb 3′ sequence from the *Hin*dIII (+660) to the *Cla*I (+1,350) of the *rbcS-E9* gene[11]. The *rbcS-E9* 3′ fragment contains only 232 bases in the transcribed region that could hybridize to the *rbcS-E9* mRNA. In these conditions, the *nos-npt*-II and *rbcS-E9* mRNA show the same hybridization signal (Fig. 5, lane 11). However, the hybridization intensity of the *rbcS-E9* transcript produced by the CaMV 35S promoter relative to that of *npt*-II produced by the *nos* promoter is ~10–15 times higher (Fig. 5, lane 9). These results indicate that the CaMV 35S promoter is ~10–15 times stronger than the *rbcS-E9* promoter in petunia calli.

Discussion

Here we describe the first functional analysis of the control sequences of a major regulated plant gene, the *rbcS-E9* gene of pea. In pea leaves[11] and in transformed petunia calli[19] the accumulation of the *rbcs-E9* mRNA is increased by light. Gallagher and Ellis[16] have shown that an effect of light is to stimulate the rate of transcription initiation of the pea *rbcS* genes. However, the extent of light-stimulated transcription obtained by these authors[16] is twofold less than the *rbcS* mRNA ratio between green and etiolated pea leaves[9,11]. To determine whether light also exerts a post-transcriptional effect on *rbcS* gene

expression, we placed the *rbcS-E9* coding sequence under the control of the 35S promoter of CaMV[25] that is insensitive to light (F.N., unpublished results). The level of the *rbcS-E9* transcript produced by the 35S promoter is the same either in the light or the dark. These results clearly exclude any pronounced light effect on post-transcriptional processing of the *rbcS-E9* transcript or its stability. In addition, they provide evidence that light-induced accumulation of the *rbcS-E9* mRNA in petunia calli reflects largely transcriptional control of its cognate promoter by light.

To map the *rbcS-E9* gene control sequences, the activities of several 5′ deletion mutants and chimaeric gene constructs were examined. Our analyses reveal that the *rbcS-E9* 5′ flanking sequence can be divided roughly into three regulatory regions. An upstream region of ~700 bp (−1,052 to −352) is needed for maximal transcription but not light–dark regulation. Mutants lacking this region show 15–20% of the wild-type activity but still retain light responsiveness. Whether this region alone may also provide a light-regulated function when joined to a heterologous promoter is being tested.

The sequence element, bordered by positions −107 to −56 and including the CAAT box at position −85, is required neither for accurate transcription nor for light induction. In fact, this element seems to have a negative regulatory function, because in its absence transcription is increased by approximately two times with no significant effect on the light-induction factor. This finding is in contrast to the results obtained with the nopaline synthase promoter[26] and the CaMV 35S promoter[25], both of which require sequences in and around the CAAT box for efficient transcription. On the other hand, there are examples of animal genes that either do not have recognizable CAAT sequence[27–30] or still retain full transcriptional activities after deletion of the CAAT sequence[31,32]. We note that in the internal deletion mutant *5′ Δ-107/-56*, a new sequence, AATCCATT, is reconstituted at ~position 60 on re-ligation of the *Bst*XI-cut sites. Although unlikely, we cannot exclude the possibility that the function of the CAAT box at position −85 may be supplanted by this new sequence at position −60 in the deletion mutant.

We have identified a 33-bp sequence fragment surrounding the TATA box involved in light control of *rbcS-E9* gene transcription based on analyses of the *rbcS-E9-cat* chimaeric gene and the *5′ Δ-35* mutant, both of which show light-induced transcription. The chimaeric gene contains the *rbcS-E9* 5′ region from −1,052 to −2. On the other hand, results from the *5′ Δ-35* mutant clearly demonstrate that sequences upstream of −35 are not needed for light-induced transcription. Taken together, we conclude that the sequence from −35 to −2, which includes the TATA box, contains the necessary information for responsiveness to light.

Comparison of the 10-bp sequence (−35 to −24) containing the *rbcS-E9* TATA box with similar regions of all the *rbcS* genes of dicotyledonous plants sequenced so far reveals a striking degree of homology (Fig. 6). Point mutations or deletions in the TATA box are known to reduce the efficiency and accuracy of transcription but have no effect on gene regulation[31,33]. In heat-shock[34], metallothionein[30] and His [35]genes, sequence elements that confer regulated transcription are found as short direct or inverted repeats 5′ upstream of the TATA box. Examination of the *rbcS-E9* light-responsive sequence reveals an 8-bp direct repeat (from −23 to −16 and from −12 to −5) with only one mismatch (at positions −19 and −8) located just downstream of the TATA box. In addition, this region also contains an imperfect palindrome (Fig. 6). Although the functional significance of these structural features remains to be elucidated, we note that the sequence between the *rbcS-E9* TATA box and its mRNA cap site is conserved in two other pea *rbcS* genes (*rbcS-3A* and *ss3.6*) and in a soybean *rbcS* gene (*srs1*). A fourth pea *rcbS* gene, *rbcS-3C*, contains only the second repeat sequence of *rbcS-E9* (Table 1). The CaMV 35S promoter–*rbcS* chimaeric gene contains one (from −13 to −2) of the repeat sequences; nevertheless, it is not light-regulated (Fig. 5), suggesting that one of the repeat sequences by itself is not sufficient to confer light responsiveness. 3′ deletion and site-specific mutagenesis in this region will allow us to investigate the relative importance of the TATA box and the direct repeats, and to define more precisely the critical sequences for light-controlled transcription.

We thank Cynthia L. Fink, Mei-Yin Hsu, Jeanne G. Niedermeyer, Karen Thurman, Sara Trillo Adams and Sara Wagner for technical assistance and Wendy Roine for assembling this manuscript. G.M. is a Fellow of the Instituto Pasteur-Fondazione Cenci Bolognetti (University of Rome) and F.N. is on leave from the Biological Research Center, Hungarian Academy of Science, Szeged, Hungary. Work done at the Rockefeller University was supported by a grant from Monsanto.

First observation of ultra-high-energy γ rays from LMC X-4

R. J. Protheroe & R. W. Clay

Department of Physics, University of Adelaide, Adelaide, South Australia 5001, Australia

Ultra-high-energy γ rays ($>10^{15}$ eV) have recently been observed from Cygnus X-3 (refs 1, 2) and from Vela X-1 (ref. 3). The discovery that some neutron star binary X-ray sources are emitting ultra-high-energy (UHE) γ rays has led to considerable interest and speculation as to the nature of the cosmic particle accelerators responsible for the γ rays[4–7] and to the notion that much of the galactic cosmic radiation above 10^{16} eV may originate from such objects[7–9]. Data from the University of Adelaide air-shower array at Buckland Park taken over a 3-year period have been analysed to search for evidence of UHE γ-ray emission from additional neutron-star binary X-ray sources having known orbital periods. We present here the result of this search and report the detection of UHE γ rays from LMC X-4 above 10^{16} eV with an integral flux of $(4.6\pm1.7)\times10^{-11}$ photons m^{-2} s^{-1}. This is the first extragalactic object to be positively detected at these energies.

Observations of air showers were made continuously (except for maintenance) during 1979, 1980 and 1981 at Buckland Park (sea level, latitude 35° S). During this time, the array[10] consisted of eleven 1-m^2 plastic scintillator detectors, five of which had fast-timing capability and were used for shower arrival direction analysis. Over the 3-year period some 1.3×10^5 air showers were recorded[11,12] with primary energies $\geq3\times10^{15}$ eV Following our detection[3] of UHE γ rays from Vela X-1, we examined the Buckland Park data to test for an excess of air showers from regions around the galactic plane and galactic centre[13], and from the directions of known sources of γ rays at 100-MeV energies[14]. Here we describe our continued search for evidence of periodic emission of UHE γ rays from neutron-star binary X-ray sources. In addition to Vela X-1, there are 14 such objects in the southern celestial hemisphere which have known orbital periods These objects are listed in Table 1 together with their type, estimated distance and orbital period. Of the neutron-star binary systems, 11 are massive and three are of low mass. Five (all massive systems) are in the Magellanic Clouds.

For each object, we examined the air showers that had apparent arrival directions within angle θ_c of the source direction. This 'resolution angle' depends on the declination[14] and has been chosen so that 72% of any primary particles from the source direction would produce air showers that appear to arrive from within θ_c of the source direction. This procedure optimizes the signal-to-noise ratio. The observed number of events, n, is given in Table 1 together with the number of background cosmic-ray events expected, $\hat{B}$, based on air showers arriving from the same declination but from different right ascensions (the exposure ratio, α, is the ratio of the solid angle contained within θ_c of the source direction to that used in determining the background). All air showers with apparent arrival directions within θ_c were included in the analysis. Because the rate of detecting air showers at fixed shower electron number drops off very steeply with zenith angle[14], the expected number of background events within θ_c of a source direction depends strongly on its declination (this is evident from the $\hat{B}$ values given in Table 1). Another consequence of this is that almost all the air showers analysed had zenith angles <45°. This is in contrast to arrays comprising detectors sensitive to the (more penetrating) muon component, such as water Cerenkov detectors, which can readily detect showers to larger zenith angles.

In our observation[3] of Vela X-1, and in the observation of Cyg X-3 by the Kiel group[1], it was assumed that the shower lateral-distribution age parameter, s, could be used to reduce the cosmic-ray background events by using only showers with large s. In both cases, the air showers containing an excess attributed to γ-ray initiated showers had only high s values. Furthermore, in observations[15] of 'muon-depleted' showers, attributed to γ rays, the mean age parameter was found to be 1.4, whereas for 'ordinary' air showers it was 1.2. This seems to justify the use of an age cut. However, no age cut was used by the Haverah Park group[2] in their successful search for UHE γ-ray emission from Cyg X-3. The distribution in shower age depends on zenith angle and hence on declination. We find that the age distribution of cosmic-ray background events is quite broad if the declination of the suspected source differs greatly from the latitude of the air-shower array. The age distribution of γ-ray showers is also expected to be broad in this case. For such sources, the use of an age cut would not be helpful because of the greater overlap in age distributions of cosmic-ray and γ-ray showers. Of the sources listed in Table 1, only 1700−377 passes nearly overhead at Adelaide and only for this case was an age cut used to reduce the background of cosmic-ray events. For all the other sources, the source declination differs from the latitude of the air shower array by more than 17° and no age cut was used.

† From ref. 23.

‡ γ-Ray flux is above the effective energy threshold E_{thr}, luminosity is per decade at 10^{16} eV assuming an E^{-2} differential photon spectrum at the source, X-ray luminosity is in the 2–11 keV range and is taken from ref 23

§ Positive detection, flux and luminosity given in text

‖ For this source, only showers with age parameters >1 3 were included in the analysis (see text)

When the observations were made, the Buckland Park array was sensitive to air showers with sea-level sizes $\geqslant 3\times10^5$ particles corresponding approximately to a primary energy of 3×10^{15} eV for nearly vertical showers. For large zenith angles, the threshold energies are higher. We have estimated the effective energy threshold of the array, $E_{\rm thr}$, for showers incident from the declination of each object considered. This was based on the average atmospheric depth of the array as seen by showers from that declination and on an attenuation length[12] of 185 g cm^{-2} appropriate to showers of sizes about 10^6 particles. The effective threshold energies are given in Table 1.

To test for evidence of periodic emission of UHE γ rays in phase with the orbital motion of each binary system, the arrival time of each air shower was converted to an orbital phase, ϕ $(0<\phi<1)$, after applying a heliocentric correction. Cosmic-ray events would be expected to have a uniform phase distribution and the hypothesis of uniformity was tested using the test statistic Y_n proposed by Protheroe[16]

$$Y_n = 2[n(n-1)]^{-1}\sum_{i=1}^{n-1}\sum_{j=i+1}^{n}(\Delta_{ij}+1/n)^{-1} \qquad (1)$$

where,

$$\Delta_{ij} = 0.5 - |[|(\phi_i-\phi_j)|-0.5]| \qquad (2)$$

This statistic was designed specifically for testing circular data for uniformity while being powerful against alternatives in the form of a uniform distribution plus a small narrow distribution at an arbitrary phase. The statistic Y_n representing the data is given in Table 1 together with the 5% and 1% critical value[16] for each object. Y_n exceeded the 5% critical value for LMC X-4 and Cir X-1 but, because 14 objects were examined, only LMC X-4 for which Y_n exceeded the 1% critical value is considered to be significant.

For the 13 other objects, 95% upper limits[17] to the expectation of the number of γ rays contributing air showers which arrive within θ_c are given in Table 1. Also given are 95% upper limits to the γ ray flux and luminosity. The latter takes into account a correction for attenuation by electron-photon cascading[18,19] involving photon-photon pair production and inverse Compton interactions with photons of the 2.7-K microwave background assuming an E^{-2} photon spectrum at the source. In the case of galactic objects, the presence of the interstellar magnetic field rapidly removes energy from the cascade through synchrotron emission and so the photon-photon interactions were treated purely as an absorption process.

Figure 1 plots Y_n against period for the 63 events observed from within 2.5° of LMC X-4. Previous measurements of the orbital period[20–22], which are also indicated, are consistent with the range of periods for which Y_n is large.

The LMC X-4 observation may actually be more significant than suggested by the 1% significance level obtained using the Y_n statistic if the peak in the phase distribution is broader than the effective window width implied by equation (1), that is about n^{-1} of the period. The phase distribution of events from within 2.5° of the direction of LMC X-4 is plotted in Fig. 2. There is a significant excess of events between phases 0.90 and 0.95 where we observe 12 events when we expect 2.65 events. The probability, p, of this occurring by chance in a particular bin, obtained using the Poisson distribution, is 2.12×10^{-5}. The phase distribution is shown binned in 20 bins in Fig. 2, but was previously binned in 10 bins and this binning and rebinning must be taken into account when assigning a significance level for the observation. For LMC X-4 alone, the probability must then be increased to $1-(1-p)^{(20+10)} = 6.36\times10^{-4}$ corresponding to a 3.2-standard-deviation observation. Because 14 sources were examined for UHE γ-ray emission, the probability that the observed phase distribution for LMC X-4 resulted from a chance fluctuation of cosmic-ray background events is $1-(1-p)^{30\times14} = 0.009$. It is, therefore, probable (99.1% confidence) that the phase distribution is not the result of a background fluctuation.

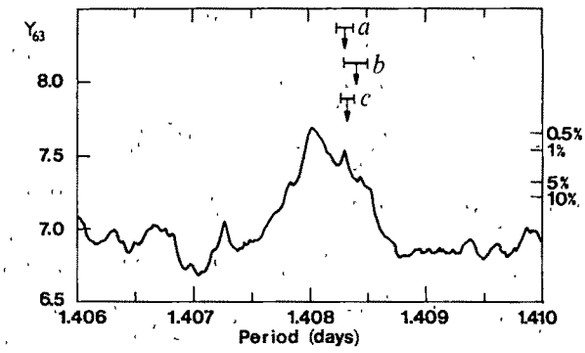

Fig. 1 The statistic Y_n derived from the phase distribution of the 63 air showers arriving from within 2.5° of LMC X-4 plotted as a function of period. Orbital periods derived by: *a*, Huchings *et al.*[21]; *b*, Lang *et al.*[22]; and *c*, Kelley *et al.*[27] are indicated.

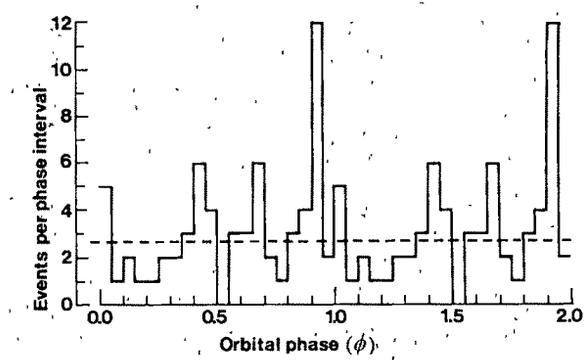

Fig. 2 Phase distribution of the 63 air showers observed within 2.5° of LMC X-4. The ephemeris of Kelley *et al.*[27] was used. The dashed line shows the expected phase distribution of the cosmic-ray background events.

We attribute the excess between phases 0.90 and 0.95, that is 9.4 ± 3.5 events, to γ rays. This corresponds to a time-averaged integral flux of $(4.6\pm1.7)\times10^{-11}$ photons m^{-2} s^{-1} above 10^{16} eV. Assuming an E^{-2} photon spectrum at the source and taking account of electron-photon cascading in the 2.7-K microwave background, we obtain a luminosity of about 10^{38} erg s^{-1} per decade, which is of the same order of magnitude as that emitted at 2–11 keV energies[23]. At ultra-high energies then, LMC X-4 has a luminosity ~20 times[2] that of Cyg X-3 and ~5,000 times[3] that of Vela X-1, making it the most luminous object known at these energies. If the magnetic field between our Galaxy and the Large Magellanic Cloud exceeds $\sim10^{-7}$ G, then the electron-photon cascade in the microwave background radiation field would be reduced by removing energy from it by synchrotron radiation[18]. In this case, to give the same flux of UHE γ rays the luminosity of LMC X-4 would need to be correspondingly higher by up to a factor of three.

Because LMC X-4 is in the Large Magellanic Cloud, some 50 kpc away, we would expect γ rays below $\sim10^{16}$ eV to be severely attenuated in traversing the 2.7-K microwave background. This should be reflected in the energy spectrum of the γ rays. Unfortunately, the effective energy threshold of the array at the time of the observations was close to 10^{16} eV for showers incident from the declination of LMC X-4 and hence no test can be made with the current data for this effect. Recent extensions[24] to the Buckland Park array have increased its sensitivity to small air showers and future observations down to $\sim10^{15}$ eV (for declination −67°) should reveal the presence of the absorption feature. Ideally, a new array at a more southerly latitude should be used to map out fully the absorption feature between below 10^{14} and 10^{16} eV. Such measurements have the potential to test the universality of the 2.7-K microwave background, measure the magnetic field between our Galaxy and the Large Magellanic Cloud, or to provide an independent measurement of the distance[25] to the Large Magellanic Cloud.

LMC X-4 is a massive binary system comprising an 07III – V or 08III – V star[21,26] with a mass of ~17 $M_\odot$ together with a ~1.6 $M_\odot$ neutron star[27] in orbit with a 1.408-day period. The X-ray source has occasional flaring episodes during which ~30% of the X rays are pulsed[27] with a period of 13.5 s, presumably the spin period of the neutron star. The inclination[27] of the system is ~66° and the X-ray source is eclipsed between phase 0.92 and 0.08. If UHE protons are accelerated in the region of the compact object UHE γ rays could be produced by nuclear interactions in the atmosphere of the companion star. In this case, we would expect γ-ray emission at orbital phases ~0.92 and 0.08 when our line-of-sight to the neutron star just grazes the star's surface. The observation of UHE γ rays at a phase of 0.90–0.95 is consistent with this picture, although the absence of UHE emission at phases 0.05–0.10 is puzzling (a similar situation exists for Cyg X-3 and Vela X-1 where only one burst of UHE γ rays is observed per orbit). The X-ray source has high and low states associated with a 30.5-day period[22] attributed to precession of an accretion disk. This precessing disk picture is supported by ultraviolet observations[28] which indicate an almost constant X-ray heating of the stellar atmosphere.

The star does not appear to fill its Roche lobe[21] and seems to have a rather low stellar wind[21,28]. Mass transfer may occur through a trailing accretion stream[21] which may feed the accretion disk. Evidence for this comes from variable obscuration of the companion star[21] between orbital phases 0.6 and 0.9 corresponding to matter trailing behind the neutron star by between 0.2 and 0.3 of an orbit. If this matter is of considerable extent above the orbital plane it could be the target material for interactions of UHE protons produced near the neutron star. Such a scenario would produce γ rays only at a phase of ~0.9 as observed.

We conclude that we have found evidence for UHE γ-ray emission by the LMC X-4 system modulated with the 1.408-day orbital period. The emission occurs when the neutron star is just entering its eclipse by the companion star and could result from nuclear interactions in the atmosphere of the companion by UHE particles produced near the neutron star. Alternatively, a trailing accretion stream could provide target material and explain the absence of UHE γ rays on leaving eclipse. Further observations in progess above 10^{15} and 10^{16} eV coupled with observations from a more southerly site at about 10^{14} eV could provide a test for the universality of the microwave background, be used as an indirect measurement of the magnetic field between our Galaxy and the Large Magellanic Cloud, or provide an independent measurement of the distance to the Large Magellanic Cloud.

We acknowledge the efforts of P. R. Gerhardy in obtaining the data-base analysed in the present work. Others particularly responsible for the development of the Buckland Park array have been J. R. Prescott, J. R. Patterson, A. G. Gregory, P. C. Crouch and D. F. Liebing. We thank D. F. Liebing and A. A. Watson for helpful comments and K. J. Orford and K. E. Turver for helpful discussions. R.J.P. thanks the Australian Government for a Queen Elizabeth II Fellowship. This work was supported in part by the Australian Research Grants Committee

Large losses of total ozone in Antarctica reveal seasonal ClO_x/NO_x interaction

J. C. Farman, B. G. Gardiner & J. D. Shanklin

British Antarctic Survey, Natural Environment Research Council, High Cross, Madingley Road, Cambridge CB3 0ET, UK

Recent attempts[1,2] to consolidate assessments of the effect of human activities on stratospheric ozone (O_3) using one-dimensional models for 30° N have suggested that perturbations of total O_3 will remain small for at least the next decade. Results from such models are often accepted by default as global estimates[3]. The inadequacy of this approach is here made evident by observations that the spring values of total O_3 in Antarctica have now fallen considerably. The circulation in the lower stratosphere is apparently unchanged, and possible chemical causes must be considered. We suggest that the very low temperatures which prevail from midwinter until several weeks after the spring equinox make the Antarctic stratosphere uniquely sensitive to growth of inorganic chlorine, ClX, primarily by the effect of this growth on the NO_2/NO ratio. This, with the height distribution of UV irradiation peculiar to the polar stratosphere, could account for the O_3 losses observed.

Total O_3 has been measured at the British Antarctic Survey stations, Argentine Islands 65° S 64° W and Halley Bay 76° S 27° W, since 1957. Figure 1*a* shows data from Halley Bay. The mean and extreme daily values from October 1957 to March 1973 and the supporting calibrations have been discussed elsewhere[4,5]. The mean daily value for the four latest complete observing seasons (October 1980–March 1984) and the individual daily values for the current observing season are detailed in Fig. 1. The more recent data are provisional values. Very generous bounds for possible corrections would be ±30 matm cm. There was a changeover of spectrophotometers at the station in January 1982; the replacement instrument had been calibrated against the UK Meteorological Office standard in June 1981. Thus, two spectrophotometers have shown October values of total O_3 to be much lower than March values, a feature entirely lacking in the 1957–73 data set. To interpret this difference as a seasonal instrumental effect would be inconsistent with the results of routine checks using standard lamps. Instrument temperatures (recorded for each observation) show that the March and October operating conditions were practically identical. Whatever the absolute error of the recent values may be, within the bounds quoted, the annual variation of total O_3 at Halley Bay has undergone a dramatic change.

Figure 1*b* shows data from Argentine Islands in a similar form, except that for clarity the extreme values for 1957–73 have been omitted. The values for 1980 to the present are provisional, the extreme error bounds again being ±30 matm cm. The

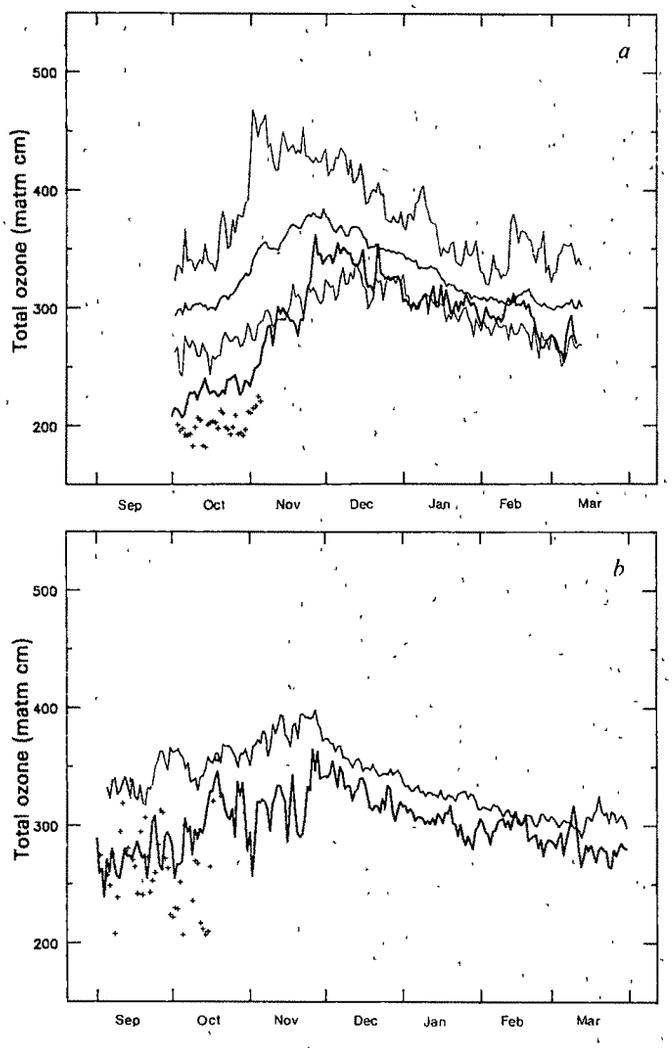

Fig. 1 Daily values of total O_3. *a*, Halley Bay: thin lines, mean and extreme values for 16 seasons, 1957–73; thick line, mean values for four seasons, 1980–84; +, values for October 1984. Observing season: 1 October to 13 March. *b*, Argentine Islands: as for Halley Bay, but extreme values for 1957–73 omitted. Observing season: 1 September to 31 March.

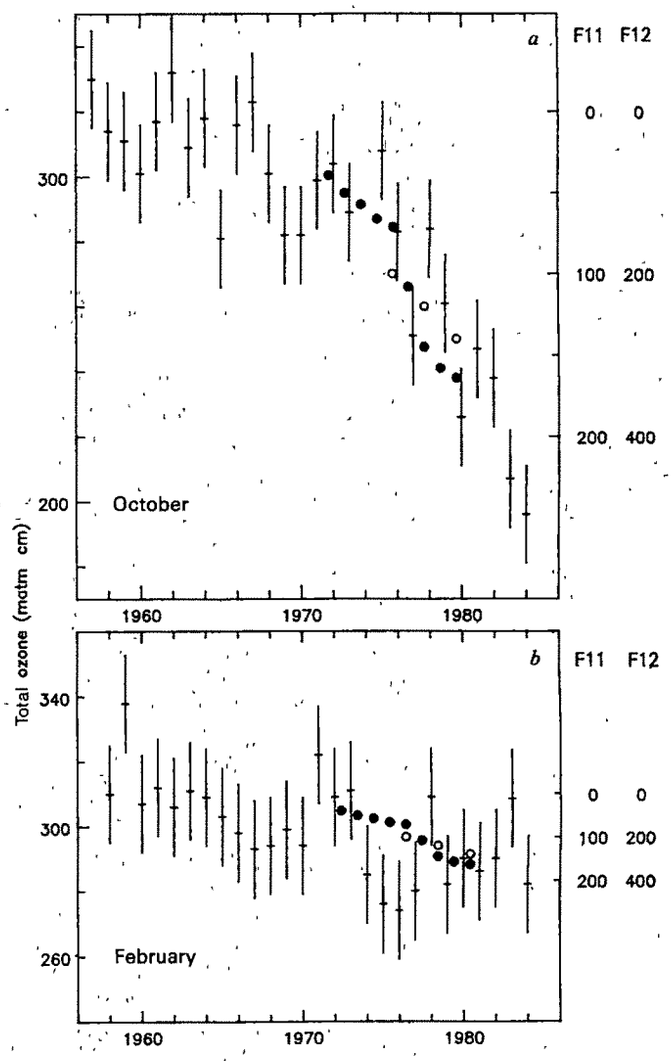

Fig. 2 Monthly means of total O_3 at Halley Bay, and Southern Hemisphere measurements of F-11 (●, p.p.t.v. (parts per thousand by volume) $CFCl_3$) and F-12 (○, p.p.t.v. CF_2Cl_2). *a*, October, 1957–84. *b*, February, 1958–84. Note that F-11 and F-12 amounts increase down the figure.

changes are similar to those seen at Halley Bay, but are much smaller in magnitude.

Upper-air temperatures and winds are available for these stations from 1956. There are no indications of recent departures from established mean values sufficient to attribute the changes in total O_3 to changes in the circulation. The present-day atmosphere differs most prominently from that of previous decades in the higher concentrations of halocarbons. Figure 2*a* shows the monthly mean total O_3 in October at Halley Bay, for 1957–84, and Fig. 2*b* that in February, 1958–84. Tropospheric concentrations of the halocarbons F-11 ($CFCl_3$) and F-12 (CF_2Cl_2) in the Southern Hemisphere[3] are also shown, plotted to give greatest emphasis to a possible relationship. Their growth, from which increase of stratospheric ClX is inferred, is not evidently dependent on season. The contrast between spring and autumn O_3 losses and the striking enhancement of spring loss at Halley Bay need to be explained. In Antarctica, the lower stratosphere is ~40 K colder in October than in February. The stratosphere over Halley Bay experiences a polar night and a polar day (many weeks of darkness, and of continuous photolysis, respectively); that over Argentine Islands does not. Figure 3 shows calculated amounts of NO_x in the polar night and the partitioning between the species[6] Of these, only NO_3 and NO_2 are dissociated rapidly by visible light. The major reservoir, N_2O_5, which only absorbs strongly below 280 nm, should be relatively long-lived. Daytime levels of NO and NO_2 should be much less in early spring, following the polar night, than in autumn, following the polar day. Recent measurements[7] support these inferences. The effect of these seasonal variations on the strongly interdependent ClO_x and NO_x cycles is examined below.

The O_3 loss rate resulting from NO_x and ClO_x may be written[8]

$$L = N + C = 2\,k_2[O][NO_2] + 2\,k_6[O][ClO] \qquad (1)$$

L accounts for over 85% of O_3 destruction in the altitude range 20–40 km. At 40 km, N and C are roughly equal. Lower down, C decreases rapidly to 10% of L at 30 km, 3% at 20 km (refs 6, 8). Equation (1) is based on two steady-state approximations, (see Table 1*a* for the reactions involved)

$$\psi = \frac{[NO_2]}{[NO]} \sim \frac{k_1[O_3] + k_4[ClO]}{k_2[O] + j_3} \qquad (2)$$

and

$$\chi = \frac{[Cl]}{[ClO]} \sim \frac{k_6[O] + k_4[NO]}{k_5[O_3]} \qquad (3)$$

valid in daytime, with [O] in steady state with $[O_3]$. Reaction (4) has a negative temperature coefficient, whereas reaction (1)

Table 1 Reaction list

a	Governing ψ and χ (see text)	
	$NO+O_3 \rightarrow NO_2+O_2$	(1)
	$NO_2+O \rightarrow NO+O_2$	(2)
	$NO_2+h\nu \rightarrow NO+O$	(3)
	$NO+ClO \rightarrow NO_2+Cl$	(4)
	$Cl+O_3 \rightarrow ClO+O_2$	(5)
	$ClO+O \rightarrow Cl+O_2$	(6)
b	Governing [Cl+ClO]	
	$HCl+OH \rightarrow Cl+H_2O$	(7)
	$ClONO_2+h\nu \rightarrow ClO+NO_2$	(8)
	$HOCl+h\nu \rightarrow Cl+OH$	(9)
	$ClO+NO_2+M \rightarrow ClONO_2+M$	(10)
	$ClO+HO_2 \nrightarrow HOCl+O_2$	(11)
	$Cl+CH_4 \rightarrow HCl+CH_3$	(12)
	$Cl+HO_2 \rightarrow HCl+O_2$	(13)
c	$HCl+ClONO_2 \rightarrow Cl_2+HNO_3$	(14)

has large positive activation energy[9], with the result that ψ is strongly dependent on [ClO] at low temperature, as shown in Fig. 4. [ClO] is not simply proportional to total ClX, because $ClONO_2$ formation (reaction (10)) intervenes. Throughout the stratosphere, $\chi \ll 1$, so that [ClO]~[Cl+ClO]. From a steady-state analysis of the reactions given in Table 1*b*,

$$[Cl+ClO] \sim \frac{k_7[HCl][OH]+j_8[ClONO_2]+j_9[HOCl]}{k_{10}[NO_2]+k_{11}[HO_2]+\chi(k_{12}[CH_4]+k_{13}[HO_2])} \quad (4)$$

Values of ψ, χ and [Cl+ClO] obtained from equations (2), (3) and (4) are in good accord with full one-dimensional model results for late summer in Antarctica[6]. Neglecting seasonal effects other than those resulting from temperature and from variation of $[NO+NO_2]$, it is possible to solve simultaneously for $[NO_2]$ and [ClO], and to derive L. Results are shown in Table 2 as relaxation times[8], $[O_3]/L$, for various conditions. The spring values (lines 2, 3 and 4) are highly dependent on ClX amount (compare columns *a* and *b*), the autumn values (line 1) much less so. At Argentine Islands, the sensitivity to ClX growth should resemble that seen in line 2, attributable solely to low temperature. Lines 3 and 4 show the enhanced sensitivity possible at stations within the Antarctic Circle, such as Halley Bay, arising from slow release of $[NO+NO_2]$ following the polar night. It remains to be shown how stable O_3 budgets were achieved with the relaxation times for the lower chlorine level (Table 2, *a*).

Much O_3 destruction is driven by visible light, but production requires radiation below 242 nm. On the dates shown (Table 2), destruction persists for some 11 h, while, because of the long UV paths, production is weak (except around noon) at 29 km, and is virtually absent below that altitude. Line 1 of Table 2 then demands O_3 transport in autumn from the upper to the lower stratosphere, which is consistent with inferred thermally-driven lagrangian-mean circulations[10]. A mean vertical velocity of 45 m per day is in good accord with calculations of net diabatic cooling[11] and gives a realistic total O_3 decay rate in an otherwise conventional one-dimensional model[6]. The short

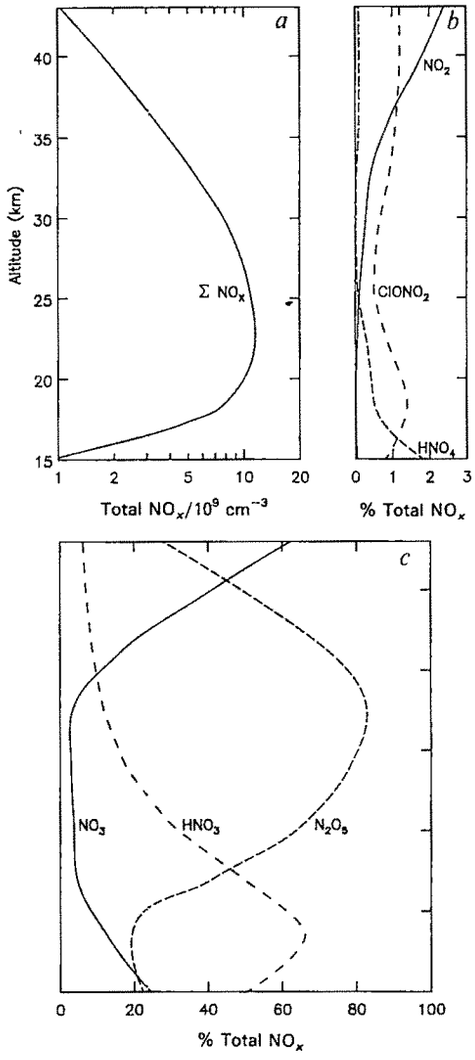

Fig. 3 NO_x during the polar night. *a*, Total NO_x cm^{-3}, from 15 to 43 km *b*, NO_2, $ClONO_2$ and HNO_4 as percentages of total NO_x. *c*, NO_3, HNO_3 and N_2O_5 as percentages of total NO_x

relaxation times in the lower stratosphere in autumn are tolerable, with adequate transport compensating for lack of O_3 production.

In early spring, on the other hand, wave activity scarcely penetrates the cold dense core of the Antarctic polar vortex and with very low temperatures the net diabatic cooling is very weak[11]. Lagrangian transport in the vortex should then be almost negligible. (The virtual exclusion of Agung dust from the vortex supports this view[5].) The final warming signals the end of this period of inactivity and is accompanied by large dynamically induced changes in O_3 distribution. However, before the warming, with low chlorine, total O_3 was in a state of near-neutral equilibrium, sustained primarily by the long relaxation times.

Noon values at 75.5° S, solar elevation 12.5°. Lower stratosphere at 230 K on 25 March; 190 K on 17 September. The altitudes shown apply to the summer temperature profile used in the model[6].

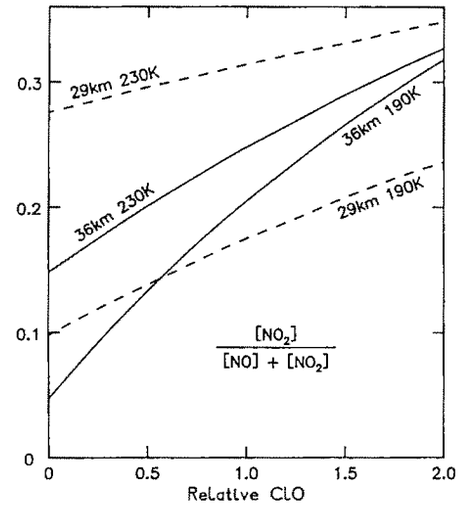

Fig. 4 $[NO_2]/[NO+NO_2]$ has the status of an efficiency factor for O_3 destruction by the NO_x cycle. In terms of the ratio ψ in the text, it is $\psi/(1+\psi)$. The figure shows how this factor varies with [ClO] at 190 K and at 230 K, at altitudes of 29 and 36 km. Values of $[O_3]$, [O], [ClO] and j_3 were taken from one-dimensional model results[6] (maximum chlorine 2.7 p.p b.v.) for noon, 25 March at 75.5° S, solar elevation 12.5°. The abscissa is [ClO] relative to the model value The rate-limiting reaction, (2) in Table 1, for the NO_x cycle has zero activation energy. Note how, nevertheless, O_3 was protected against destruction by NO_x at low temperatures in a stratosphere with small amounts of ClX, but is losing this protection as ClX grows.

With higher chlorine, relaxation times of the order seen in line 4, Table 2, entail more rapid O_3 losses. With negligible production below 29 km and only weak transport, large total O_3 perturbation is possible. The extreme effects could be highly localized, restricted to the period with diurnal photolysis between polar night and the earlier of either the onset of polar day or the final spring warming. At the pole $[NO+NO_2]$ rises continuously after the polar night, with the Sun. The final warming always begins over east Antarctica and spreads westwards across the pole. At Halley Bay the warming is typically some 14 days later than at the pole. Maximum O_3 depletion could be confined to the Atlantic half of the zone bordered roughly by latitudes 70 and 80° S.

Comparable effects should not be expected in the Northern Hemisphere, where the winter polar stratospheric vortex is less cold and less stable than its southern counterpart. The vortex is broken down, usually well before the end of the polar night, by major warmings. These are accompanied by large-scale subsidence and strong mixing, in the course of which peak O_3 values for the year are attained. Hence, sensitivity to ClX growth should be minimal if, as suggested above, this primarily results from O_3 destruction at low temperatures in regions where O_3 transport is weak.

We have shown how additional chlorine might enhance O_3 destruction in the cold spring Antarctic stratosphere. At this time of the year, the long slant paths for sunlight make reservoir species absorbing strongly only below 280 nm, such as N_2O_5, $ClONO_2$ and HO_2NO_2, relatively long-lived. The role of these reservoir species should be more readily demonstrated in Antarctica, particularly the way in which they hold the balance between the NO_x and ClO_x cycles. An intriguing feature could be the homogeneous reaction (Table 1*c*) between HCl and $ClONO_2$. If this process has a rate constant as large as 10^{-16} cm^3 s^{-1} (ref. 2) and a negligible temperature coefficient, the reaction would go almost to completion in the polar night, leaving inorganic chlorine partitioned between HCl and Cl_2, almost equally at 22 km for example. Photolysis of Cl_2 at near-visible wavelengths would provide a rapid source of [Cl + ClO] at sunrise, not treated in equation (4). The polar-night boundary is, therefore, the natural testing ground for the theory of non-linear response to chlorine[1,2]. It might be asked whether a nonlinear response is already evident (Fig. 2*a*). An intensive programme of trace-species measurements on the polar-night boundary could add greatly to our understanding of stratospheric chemistry, and thereby improve considerably the prediction of effects on the ozone layer of future halocarbon releases.

We thank B. A. Thrush and R. J. Murgatroyd for helpful suggestions.

An Ordovician ophiolite in County Tyrone, Ireland

D. H. W. Hutton*, M. Aftalion† & A. N. Halliday†

* Department of Geological Sciences, University of Durham, Durham DH1 3LE, UK
† Scottish Universities Research and Reactor Centre, East Kilbride, Glasgow G75 0QU, UK

Ophiolites are regarded widely by geologists as remnants of old oceanic crust that has been obducted onto the continental margins during ocean or marginal basin closure and orogeny. Therefore, they provide evidence for the existence of old oceans and oceanic basins and are a key to the extension of plate tectonic modelling into pre-Mesozoic rock assemblages. In the Caledonide–Appalachian orogen, ophiolites are known although very few of these are dated well enough to provide accurate constraints on plate-tectonic kinematics. We report here the discovery of an ophiolitic sequence within the rocks of the Tyrone Igneous Complex in Northern Ireland. U/Pb dating combined with field evidence indicates that the Tyrone ophiolite was formed and then obducted onto the northern margins of the Iapetus Ocean close to 470 Myr BP (Arenig).

The Tyrone Igneous Complex (Fig. 1) occurs in an approximate along-strike continuation of the Midland Valley of Scotland; it is partly overlain by Upper Palaeozoic sediments within a shallow graben structure bounded by Dalradian rocks to the north and the Lower Palaeozoic of the Southern Uplands–Longford–Down zone to the south. The complex consists of three units (Fig. 1): a middle Ordovician (Llandeilo–Caradoc) volcanic sequence; a high metamorphic grade gneiss unit 'the central inlier'; and a unit of gabbros and dolerites previously called 'the basic plutonic complex'[1]. Opinions on the age relationships and significance of the units have varied. Originally the basic plutonic complex and volcanics were grouped together as Llandeilo–Caradoc and regarded as being altogether younger and in tectonic contact with the central gneisses[2]. Alternatively, the basic complex has been correlated with layered basic intrusions of Connemara and Aberdeenshire. This led to the view that both basic rocks and gneisses were older than and in unconformable contact beneath the Ordovician volcanic sequence[3].

Reconnaisance remapping and reassessment of the 'basic plutonic complex' (D.H.W.H.) indicates that this is part of an ophiolite 35 × 10 km in area. The lowermost exposed part of this is essentially gabbroic with variably developed cumulate layering[4] as well as leucogabbros and isotropic and pegmatoid gabbros. Overlying this and previously unrecognized as such is a sheeted dyke complex. This is most clearly seen in Carrickmore Quarry [609 721] (Irish National Grid), which exposes 100% dolerite made up of parallel dykes averaging 1 m in thickness. These intrude each other to produce both two-sided chills and, more commonly, the classic one-sided chilled margins typical of sheeted dyke complexes. Elsewhere in the Carrickmore area and along strike for 18 km to the north-east and in another slice of the ophiolite to the north, this dolerite is found and is composed entirely of dykes cutting dykes. The dykes in the complex have general north-east south-west trends and are vertical-to-moderately south dipping. In the lower parts of the sheeted complex the dykes are often deformed parallel to their margins. Overlying the dolerites and so far recorded in only two localities (Carrickmore[2], and Craigballyharky [732 755]) are a few metres of spilitized basaltic pillow lavas with thin chert screens and fragments.

Separating the sheeted dyke complex from the gabbros is a complicated transition zone. This contains early sheeted-dyke dolerites, often strongly deformed, which are cut and intruded by isotropic and pegmatitic gabbros as irregular bodies and veins. This zone is probably the result of repeated intrusion of the gabbro magma chamber in the vicinity of the spreading centre into the overlying sheeted-dyke complex. The deformed dolerite dykes probably represent ductile extension fault development sub-parallel to the dykes, a consequence of newly formed oceanic lithosphere subsiding away from the ridge crest during cooling and crystallization[5].

Within the lower part of this zone and in the gabbro unit, at, for example, the Scalp[4] [636 745], there are common small intrusive sheets, bodies and net vein systems of tonalite, quartz diorite and trondjemite. These have complex time relationships with the basic rocks and the deformation and are interpreted as silicic differentiates from the developing ocean crust. Apart from older records of small serpentine occurrences in Tyrone and the identification in the present study of clinopyroxenite pegmatites (thought to be typical of the gabbro-peridotite contact in ophiolites[6]), there are no ultrabasic rocks present. This is probably the result of thrusting, because all the external contacts of the ophiolite are tectonic.

A feature of the entire basic complex that previous models could not easily explain is the widespread development of moderate-to-high-grade metamorphism. The gabbros and dolerites are irregularly uralitized to epidote amphibolite metamorphic assemblages without, in general, any accompanying deformation. This is typical of the metamorphism of many ophiolites and is probably the result of metasomatic metamorphism by circulating hot brines in the oceanic environment[7].

The sequence described above, which occurs in two tectonic slices separated by the central inlier, is clearly part of an ophiolite[8]. The bottom of the ophiolite has been removed

Table 1 U/Pb isotope data for zircons from Craigballyharky pluton, Tyrone

* All size fractions analysed were non-magnetic at a side inclination of 1°. Uncertainty in $^{207}Pb/^{235}U$ and $^{206}Pb/^{238}U$ estimated at 0.3% and 0.2% (1σ) respectively. Regression of data using the method of York[27] yields upper intercept of $2{,}030^{+630}_{-500}$-Myr BP and lower intercept of 471^{+2}_{-4}-Myr BP (SUMS = 0 52) All isotope measurements were made using a VG Micromass MM308 mass spectrometer.

tectonically and much of the uppermost (basalt-sediment) part has been removed by tectonism or erosion or both. The Tyrone ophiolite is not equivalent to the Connemara and Aberdeenshire layered basic complexes by virtue of its structure and its non-intrusive nature.

The Tyrone ophiolite is cut by a number of small granitic plutons, many of which are biotite and hornblende granites and granodiorites and may be Devonian in age[2]. The Craigballyharky pluton however, which occurs near the village of Pomeroy [732 755], is a tonalite quartz-diorite granodiorite body that intrudes the ophiolite. The marginal quartz diorite of the Craigballyharky intrusion has a hybrid igneous character that has been interpreted as the result of interaction and mixing between the ophiolitic basic country rocks and the intruding central tonalite magma[9]. To achieve such mixing, the basic rocks themselves must have been at quite a high temperaure. As there is no evidence in the area for a separate post-obduction pre-granite heating event of the ophiolite, this high temperature must have been a relic of the ophiolite ocean floor metamorphism. Thus the age of emplacement of the tonalite must approximate the age of the ophiolite itself or be slightly later than it.

In Table 1 we report U/Pb isotope data for three zircon size fractions from a sample of the main tonalite unit at Craigballyharky. Techniques are described elsewhere[10] and are summarized in the table footnote. The results are moderately discordant and when plotted on a conventional concordia diagram (Fig. 2) define a discordia line with a lower intercept of 471^{+2}_{-4} Myr BP and an upper intercept of $2{,}030^{+630}_{-500}$ Myr BP (2σ).

We interpret the lower intercept as the age of intrusion of the Craigballyharky tonalite. This, from the foregoing arguments, places close constraints on the age of the ophiolite itself, which was formed at or just before 471^{+2}_{-4} Myr BP (Arenig) The ophiolite is therefore older and quite distinct from the Llandeilo-Caradoc (~455 Myr BP) volcanic sequence with which it has been correlated in the past.

The upper intercept indicates that the source of the magma and/or the material assimilated by the magma contained zircons of early Proteozoic age. This result is very similar to that obtained for zircons in Ordovician greywackes from the Southern Uplands of Scotland[10] and also from a metasedimentary granulite-facies xenolith from a vent in the Midland Valley of Scotland[11]. The U concentrations of the Craigballyharky zircons (Table 1) are among the lowest recorded from rocks of the British Isles and are very similar to those of zircons from the Ballantrae trondjemite[12] and to zircons from, again, the Midland Valley granulite-facies xenolith[11]. Such low concentrations are expected from granitic regimes that have been melted from basic oceanic crust or from granulite facies continental crust. A plausible explanation to these data, therefore, is that the tonalite represents a mixture of both a mafic component from a relatively young ocean crust and a felsic component from old (Proterozoic) continental crust. We suggest that this crust was part of the northern continental margin to the Iapetus Ocean at this time. Thus, the tonalite rose through the margin and cut the ophiolite very soon after it had been obducted. Hence ophiolite formation and obduction occurred close together in time at 471^{+2}_{-4} Myr BP (Arenig).

The age of the Tyrone ophiolite compares well with the age of the Bay of Islands complex (475–515 Myr BP)[13,14], Ballantrae (~480 Myr BP)[12,15], Shetland (465–479 Myr BP)[16] and Thetford in Quebec (~490 Myr BP)[17]. The Tyrone data provides an important link between the Newfoundland and Scottish ophiolites and confirms that, during the late Tremadoc-Arenig, ophiolite formation and obduction was probably widespread along the Caledonide-Appalachian system. In the British Isles it is perhaps significant that the Caledonian ophiolites north of the Iapetus suture all lie in the Midland Valley of Scotland and its extension into Ireland. Thus, in Scotland the ophiolitic fragments of early Arenig age or older that occur in the Highland Border complex[18] may be comparable with at least part of the Ballantrae ophiolitic sequence seen further to the south[12,15] (Fig. 1). In Ireland, Tyrone, the largest of these ophiolites, has obvious similarities in both age and setting to Ballantrae. Further west in Ireland the undated Clew Bay ophiolitic melange[19] and the Achill Island serpentinitic melange[20] are disrupted Caledonian ophiolites that may be compared with the Highland Border rocks. Also, nearby in the Ox Mountains, small scraps of Caledonian serpentinite are recorded[21]. One view of these ophiolite occurrences in the Midland Valley is that a closed ocean or oceanic basin is concealed at the site of the Highland Boundary or Southern Uplands fault[19,22]. An alternative view, presented here, is that the Midland Valley basement is part of the Proterozoic North American continental margin to Iapetus, onto which ophiolites were obducted from the south during the Ordovician The Highland Boundary and Southern Upland fault have been identified recently[23,24] as long lived Palaeozoic transcurrent faults. We suggest that the Midland Valley became detached from the North American continent along these faults by sinistral movements, probably culminating in the early Devonian[25,26], which displaced this allochthonous terrane northeastwards into its present position.

Seismic sequences in Greece interpreted in terms of barrier model

G. F. Karakaisis, B. G. Karacostas., E. E. Papadimitriou, E. M. Scordilis & B. C. Papazachos

Geophysical Laboratory, University of Thessaloniki, Thessaloniki, Greece

Between 1978 and 1981, five shallow main shocks occurred in Greece and the surrounding region. Here we consider the space–time distribution of the foreshocks and the aftershocks of these earthquakes by interpreting the migration characteristics of the epicentres in terms of the barrier model[1]. This model suggests that segmented ruptures can occur in a seismic fault but that the rupture front may be stopped by a barrier, or may propagate over the whole fault plane leaving the barrier unbroken. These unbroken barriers result in aftershocks due to the concentration of stress there, and cause migration of major events along a plate boundary. This migration may be an important factor for the prediction of earthquakes.

According to the barrier model, segmented ruptures could occur in a seismic fault, that is, slip could occur in cracks during the fault rupture process, while the region between cracks remains unbroken after the rupture. A rupture front may be

stopped by a barrier, but elastic waves generated by the slip can break the fault plane ahead of the barrier. Then, the rupture can propagate over the whole fault plane to leave the barriers unbroken The residual stress over the fault plane immediately following the rupture is not uniform. Consequently, the stress will concentrate at the unbroken barriers[2] and cause aftershocks. Barriers also cause migration of major events along a plate boundary, such as the westward migration of great earthquakes[3] on the Anatolian fault which took place between 1939 and 1944.

During 1978–81, five shallow main shocks with surface wave magnitudes ≥ 6.5 occurred in Greece and the surrounding area. Table 1 lists the focal coordinates (φ, λ, h), the surface wave magnitude (M_s), number of observations (N), mean error of the origin time (r.m.s.), and mean error in the location (ERH, km) for the main shocks.

To determine accurate locations of the epicentre and the focal depth, we used the HYPO 71 computer program[8], adopting a two-layer crustal model above a half space[9] with the following thicknesses (d_i) of the layers, and velocities (V_i); $d_1 = 19.0$ km, $V_1 = 6.0$ km s^{-1}, $d_2 = 12.0$ km, $V_2 = 6.6$ km s^{-1}. The P-wave velocity in the half space has been taken as 7.9 km s^{-1}. The accuracy in the determination of the focal parameters has been improved by using time delay corrections[10] on the arrival times at the seismological stations in Greece and neighbouring countries. The average ERH for all the shocks of the five seismic sequences is satisfactory for our purpose, being 2.0 ± 0.9 km.

Figure 1 is a map of Greece and of the surrounding area showing the strikes of the faults producing the five seismic sequences The main source parameters of these earthquakes are known[11]. To investigate the space-time distribution of the epicentres of the five seismic sequences, the position of the epicentre projection on the strike direction of the fault plane, which is the largest dimension of the aftershock area, is plotted against time for each sequence. The distances from the epicentre, x, are always measured from a point, A, which is located at one of the two ends of the fault's strike, because the epicentre migration takes place parallel to this direction.

Figure 2 shows the space-time diagrams of the five seismic sequences. In three of these, the main shock was preceded by smaller shocks. In the Thessaloniki 1978 seismic sequence (Fig. 2*a*), these shocks migrated towards the main shock epicentre, that is, from east to west, while in Montenegro 1979 and Magnesia 1980 seismic sequences (Fig. 2*b*, *c*) these shocks are very closely related, in space and time, with the main shock. This clearly shows that these earthquakes are real foreshocks of the three main shocks.

In all five cases, after the main shock, the aftershock activity expanded from the focus of the main shock to one (Fig. 2*a*, *c*, *d*) or both ends (Fig. 2*b*, *e*) of the fault, reaching these ends after 2 h, 24 min, 7 h, 15 min and 30 min respectively

Figure 2 shows that parts of the faults do not have aftershocks. For example the central parts of the faults which produced the Monte-Negro 1979 (Fig. 2*b*), the Magnesia 1980 (Fig. 2*c*), the Alkyonides Gulf 1981 (Fig. 2*d*) and the Northern Agean 1981 (Fig. 2*e*) seismic sequences. These are the parts of the faults which presumably slipped smoothly during the main shocks. The dashed circles in Fig. 2*d* denote shocks related to an antithetic fault parallel to the main fault.

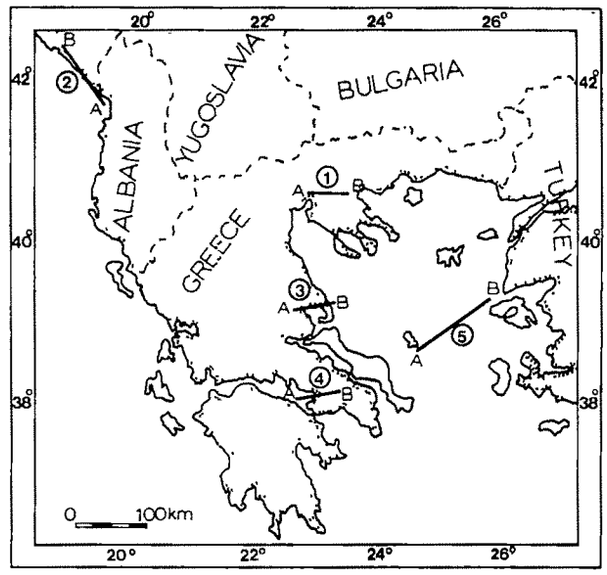

Fig. 1 Index map indicating the strikes, AB, of the main faults of the five seismic sequences Migration of these shocks in each sequence was investigated along these strikes Positions 1–5 correspond to *a*–*e* of Fig. 2

The aseismic slip induced high tectonic stress at one or both ends of the fault where the clustering of aftershocks is observed The clustering probably indicates the sites of the barriers where high stress was induced following the main shocks.

After a time interval, which varies from sequence to sequence, the stress reached the barrier's ultimate strength, breaking the strongest barrier and producing the largest aftershock in each seismic sequence.

Three out of five main shocks with $M_s \geq 6.5$ were preceded by recorded foreshocks. These foreshocks started 5 to 42 days before the main shocks and were either very close to the epicentres of the main shocks or their epicentres migrated to the epicentres of the main shocks. Detailed studies of foreshocks could, therefore, contribute to the prediction of the main shocks.

In three of the seismic sequences, the focus of the main shock was located in the middle section of the fault; in the other two cases, it was located near one end of the fault. Thus, the focus of the main shock can be anywhere in the fault.

In all five cases, the aftershock activity expanded to one or to both ends of the fault after the main shock and reached these ends within one day. In all five cases, the largest aftershocks occurred near the one end of the fault within a time period which varied from sequence to sequence between 15 min and 38 days after the main shock. This observation shows that a continuous monitoring of the aftershock activity can lead to the prediction of the epicentre of the largest aftershocks which sometimes produce damage comparable with that of the main shock.

The barrier model gives a general explanation of the occurrence of the shocks of the seismic sequences, but detailed knowl-

The origin of authigenic ankerite from the Ninian Field, UK North Sea

J. D. Kantorowicz*

Department of Geology, University of Hull, Hull HU6 7RX, UK

The carbonate minerals ankerite and ferroan dolomite are widely reported in studies of concretions[1,2] and of sandstone hydrocarbon reservoirs[3–8]. These minerals are often thought to have formed relatively late in the sandstones' diagenetic history and in the Gulf Coast their occurrence has been linked to clay mineral diagenesis in the surrounding shales[9]. I describe here authigenic ankerite from the Ninian Field[10]. Ankerite formation was probably synchronous with hydrocarbon emplacement and is related to clay mineral diagenesis in the hydrocarbon source rocks of the Viking Graben. It occurs throughout the reservoir sandstones but is particularly abundant below the oil–water contact. This distribution reflects hydrocarbon emplacement arresting diagenesis at progressively deeper levels of the reservoir. The resulting preferential cementation may adversely affect transmissibility between the aquifer and the oil column and consequently could reduce hydrocarbon recovery.

Two forms of authigenic ankerite are observed in cores from Wells 3/3-1, -2 and -3 from the Ninian Field in the northern North Sea. The reservoir comprises Middle Jurassic Brent Group sandstones[10] and is characterized by a complex diagenetic mineralogy including clay minerals, quartz and feldspar overgrowths, siderite, pyrite, calcite and barytes[11]. The two forms of ankerite occur irrespective of depositional facies and enclose and replace the earlier formed authigenic minerals. The first form is concretionary and occurs in finer-grained sediments. It comprises large poikilotopic crystals several millimetres in length which totally fill pore space and constitute 23–50% of the bulk rock volume. The second form is discrete pore-filling rhombs, 20–40 μm in length which form up to 1% of the bulk rock volume above the oil–water contact, but up to 5% below.

Carbon and oxygen stable isotope ratios of ankerite samples are compiled in Table 1. Carbon isotope ratios can provide information on the origin of the bicarbonate in carbonate minerals[1]. Carbonates precipitating from seawater have a $\delta^{13}C$ of 0‰ PDB. Also, carbonates incorporating bicarbonate from specific bacterial degradation reactions have specific $\delta^{13}C$ compositions of −20 to −25 or +15‰ (ref. 1) or intermediate values if bicarbonates are liberated by more than one mechanism. The carbon isotope compositions of these ankerite samples ($\delta^{13}C$ −7.1 to −13.6) are not indicative of a specific source of bicarbonate. These values could result from precipitation in pore waters supplied by two sources of bicarbonate. Alternatively, this composition could reflect the dissolution, equilibration and reprecipitation, of *in situ* carbonate cements of one

* Present address Koninklijke/Shell Exploratie en Produktie Laboratorium, Volmerlaan 6, Rijswijk, The Netherlands

isotopic composition with CO_2 produced during abiotic degradation of organic matter or hydrocarbon maturation.

Oxygen isotope ratios can, in certain circumstances, provide information on the temperature of mineral precipitation. During isotopic equilibrium precipitation, the $\delta^{18}O$ composition of a carbonate is related to both the temperature of precipitation and the composition of the fluid from which it precipitated. Assuming the pore waters to have been Jurassic seawater ($\delta^{18}O = 1.2‰$)[12] the temperature at which ankerite precipitated is estimated to be ~115 °C. Because the isotopic composition of the pore waters from which ankerite precipitates is unknown this temperature is unlikely to be accurate. However, the isotopic composition is consistent with precipitation from isotopically light, and/or hot pore waters[1,3,6]. Interpretation of the isotopic data confirms petrographical observations. Ankerite authigenesis was late in the diagenetic sequence and occurred at a 'temperature' approaching the present reservoir temperature of 100 °C (ref. 10). Precipitation probably involved CO_2 generated in a hotter, more deeply buried hydrocarbon-source rock in the Viking Graben and was related to Tertiary hydrocarbon migration into the reservoir[10,13-15].

Electron microprobe analysis reveals various chemical compositional trends within individual crystals. These trends reflect local fluctuating pore-water compositions during precipitation. However, the data as a whole exhibit a gradual decrease in $CaCO_3$ content with increasing depth (Fig. 1). It is suggested that this gross compositional change reflects evolving pore-water composition. When ankerite precipitation began throughout the reservoir pore waters were more calcium-rich. As hydrocarbons filled the reservoir, the precipitation of ankerite continued but pore-water composition changed progressively. The last ankerite precipitation occurred below the present oil–water contact, in relatively calcium-depleted pore waters.

Dissolution of, and equilibration with, earlier formed calcite or siderite respectively could have supplied the Ca^{2+} or Fe^{2+} required for ankerite precipitation. The replacement of calcite certainly may be implied from the high-minus cement porosities of the concretionary ankerites. However, ankerite, siderite and calcite coexist in the water. If dissolution and equilibration did take place, calcite dissolution would have become unfavourable during later precipitation when equilibrium was reached. This would explain the chemical compositional trends seen in the ankerite. Mg^{2+}, however, must have been introduced from outside the system, there being no precursor Mg^{2+}-bearing minerals present. In the Gulf Coast[3,9], ankerite formation in sandstones is related to mudrock diagenesis in the surrounding shales. The replacement of smectite by illite releases Mg^{2+} and Fe^{2+} into solution[9], at temperatures which mark the onset of hydrocarbon migration[9,13,14]. In both the hydrocarbon source rocks of the Viking Graben, and elsewhere in the North Sea, the replacement of smectite by illite has occurred and cation release is likely to have overlapped hydrocarbon generation[13,14].

It is postulated that ankerite began to form in the Ninian Field during hydrocarbon emplacement, as the invading pore waters reached equilibrium with the formation. In view of the sealed nature of the reservoir during hydrocarbon accumulation, fluid flow must have been convective[16]. Poikilotopic ankerite began to form by nucleating on and replacing preexisting authigenic calcite. Ubiquitous pre-filling rhombs also formed at this time. Ankerite precipitation continued below the oil–water contact as hydrocarbons arrived but was arrested as the oil column grew progressively while the reservoir filled. As Fe^{2+} and Mg^{2+} continued to arrive in the hydrocarbon-bearing fluids, pore-water compositions changed, leading to formation of progressively Ca^{2+} poorer ankerite with increasing depth (Fig. 1). The earlier formed cements now occur in the oil-bearing sandstones and the discrete pore-filling ankerite rhombs both in the oil and below the oil–water contact in the aquifer, having formed as saturated pore waters were displaced downwards by the accumulating hydrocarbons. Late stage ferroan carbonates and ankerites are reported from reservoirs elsewhere[3-6]. In view of the widespread association of altering smectites and maturing source rocks[9,13], many may have a similar origin, although this has not been widely recognized[17].

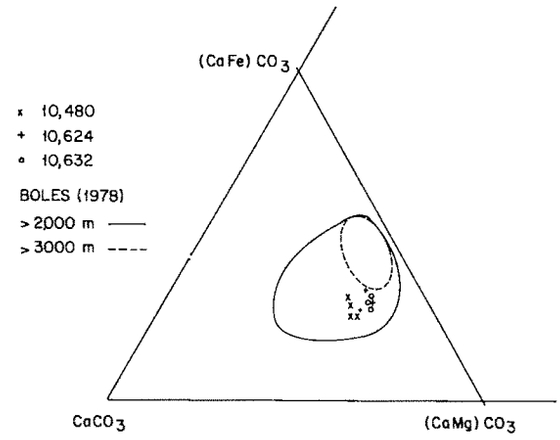

Fig. 1 Chemical compositional trends of ankerite from the Ninian Field. Data points are labelled in core or drillers depths. The oil–water contact in 3/3-3 occurs at 10,503 feet drillers depth (3201.3 m). Electron microprobe analyses were performed with a Links Systems Model 290 energy dispersive analyser fitted to a Cambridge Instruments Geoscan. The operating conditions were beam voltage 15 V, specimen current 2.5 nA and beam width 1 μm. The raw data were recalculated with a Links Systems ZAF 4 software package. Depths of the three cores in metres are 3,194.3 m, 3,238.2 m and 3,240.6 m, respectively.

In the Gulf Coast, ankerite authigenesis is reported to be succeeded by the replacement of kaolinite by chlorite[9]. This reaction is also related to the release of Fe^{2+} and Mg^{2+} during smectite's transformation to illite[9]. In the Ninian Field and in Brent Group sandstones elsewhere, chlorite is only reported to occur in the Broom Formation[11] and it is not interpreted as replacing kaolinite[11]. This could be due to the sediments not having reached the appropriate pore-water conditions. Alternatively, the Gulf Coast model may not be universally applicable as shown by the doubt concerning the original concept of the reaction's structural mechanism[18].

In the Ninian Field, porosities at the oil–water contact are not reduced significantly by ankerite precipitation[10]. Indeed, ankerite is disseminated throughout the reservoir sequence. Authigenesis here has been promoted by metal cations and bicarbonate released from hydrocarbon-source rocks, and progressively arrested by the arrival of hydrocarbons. By contrast, with rapid hydrocarbon accumulation and a plentiful supply of bicarbonate and metal cations, ankerite-forming pore waters could be displaced into the aquifer thus concentrating its formation at the oil–water contact. Also, light hydrocarbon generation and emplacement before clay mineral rection releasing cations

Table 1 Stable isotope ratios for authigenic ankerite

Well	Core depth (feet)	$\delta^{13}C$	$\delta^{18}O$	Precipitation temperature (°C)
3/3-1	9,916	−9.7	−15.2	144
3/3-3	10,330	−7.1	−10.3	96
3/3-3	10,456	−13.6	−12.9	120
3/3-3	10,502	−9.4	−10.5	98

The samples were cleaned with 1% sodium hypochlorite[19] to remove hydrocarbons and organic matter and reacted with phosphoric acid at 25 °C for 2 h. The CO_2 evolved was analysed with a Micromass 903 mass spectrometer and the raw data corrected using the normal methods[20,21]. Stable isotope ratios are reported as δ‰ variations from PDB standard, corrected with a fractionation factor of 1.01109 (ref. 22). Hypothetical precipitation temperatures for ankerite were determined assuming ankerite–water fractionation to be similar to dolomite–water[23]. Depth given in feet; equivalents in metres are 3,022.4 m, 3,148.6 m, 3,187.0 m and 3,201.0 m, respectively.

would restrict ankerite anthigenesis to below the oil–water contact. Thus, whilst high porosity and effective permeability might exist within both the oil column and the aquifer, connection between the two could become impaired. This possibility should be evaluated during reservoir development planning because any such transmissibility barrier could restrict the flow into the reservoir of either a natural aquifer or injection water. Both the loss of pressure support and the disruption of an injection pattern could adversely affect hydrocarbon recovery.

This research was carried out at the University of Hull whilst in receipt of NERC grant GT4/79/GS/39, and at the British Geological Survey (NERC) Stable Isotopes Unit. I thank the director of the BGS, Chevron Petroleum Ltd and Shell International Petroleum Maatshappij for permission to publish this paper. M. L. Coleman, R. S. Haszeldine and A. P. Heward commented on early versions of the manuscript.

Anomalous ^{13}C enrichment in modern marine organic carbon

Marine organic carbon is heavier isotopically (^{13}C enriched) than most land-plant or terrestrial organic C[1]. Accordingly, $\delta^{13}C$ values of organic C in modern marine sediments are routinely interpreted in terms of the relative proportions of marine and terrestrial sources of the preserved organic matter[2,3]. When independent geochemical techniques are used to evaluate the source of organic matter in Cretaceous or older rocks, those rocks containing mostly marine organic C are found typically to have lighter (more-negative) $\delta^{13}C$ values than rocks containing mostly terrestrial organic C. Here we conclude that marine photosynthesis in mid-Cretaceous and earlier oceans generally resulted in a greater fractionation of C isotopes and produced organic C having lighter $\delta^{13}C$ values. Modern marine photosynthesis may be occurring under unusual geological conditions (higher oceanic primary production rates, lower P_{CO_2}) that limit dissolved CO_2 availability and minimize carbon isotope fractionation[4].

In a recent compilation of geochemical analyses of samples of middle Cretaceous organic C-rich strata from numerous Deep Sea Drilling Project (DSDP) sites and several land sections[5], we failed to observe a consistent relationship between organic carbon $\delta^{13}C$ and independent geochemical indicators of marine

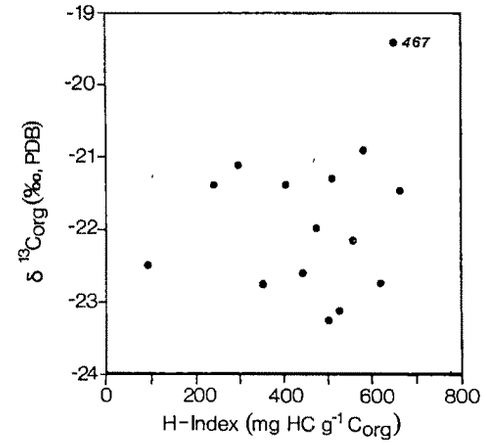

Fig. 1 Plot of $\delta^{13}C$ of organic C against Rock-Eval pyrolysis hydrogen index for organic C-rich sediments of Pleistocene–Miocene age from offshore California, DSDP Leg 63, Site 467. Hydrogen index is pyrolytic hydrocarbon yield per unit organic carbon in mg per g.

and terrestrial organic matter for samples older than Miocene. In fact, the Cretaceous sequences examined in the greatest detail usually showed the reverse of the expected relationship; that is, samples with the lightest (or apparently terrestrial) $\delta^{13}C$ values had chemical compositions indicating the greatest contributions of marine organic matter.

This apparently anomalous ^{13}C depletion in organic C of ancient sediments has been noted by others[6], and is particularly troublesome in rocks older than Silurian[7], or before the development of land plants. We conclude that organic C derived from marine plants in rocks that are Cretaceous or older typically have $\delta^{13}C$ values that are ~5–7‰ more negative than marine organic carbon in Holocene sediments.

Other techniques used to evaluate marine against terrestrial organic matter include atomic H/C ratios[8], microscopic examination of isolated organic-matter particles[9], abundance of phenolic lignin degradation products[3], organic $^{15}N/^{14}N$ ratios[10] and ^{13}C-nuclear magnetic resonance spectroscopy[11]. In general, the relative proportions of marine and terrestrial organic matter indicated by these techniques are consistent with the proportions inferred from bulk organic C $\delta^{13}C$ values in modern marine sediments.

For the data sets that we have compiled[5], the most common measure of H content is the H index from Rock-Eval pyrolysis, which has been shown to correlate with atomic H/C ratios[12]. We plot organic C $\delta^{13}C$ against H index or atomic H/C of organic matter and observe either a positive correlation or no correlation for organic C rich sequences of Holocene–Miocene age. Figure 1 shows a typical lack of correlation for Holocene–Miocene sediments from offshore southern California[5]. Here, essentially all of the organic matter is from marine productivity induced by upwelling. This marine organic matter has $\delta^{13}C$ of ~−23 to −21‰, regardless of H content.

For Cretaceous and older organic C-rich sequences, the data commonly show a negative correlation between H index and $\delta^{13}C$ of organic matter. Figure 2 illustrates data from four different middle Cretaceous organic C-rich limestone sequences. These data sets were selected to minimize possible effects of differences in preparation procedures and lithology. In general, middle Cretaceous organic C-rich strata in the North American Basin of the western North Atlantic Ocean contain predominantly terrestrial organic matter, the abundance of which is greatest at those sites closest to the North American continental margin[9,13]. In contrast, middle Cretaceous strata at DSDP sites adjacent to the African continental margin contain predominantly marine organic matter[9,13]. Figure 2*a* shows $\delta^{13}C$ and H index data for interbedded Neocomian white limestones and black marlstones of the Blake-Bahama Formation[14] cored at DSDP Site 603, one of the most terrestrially influenced

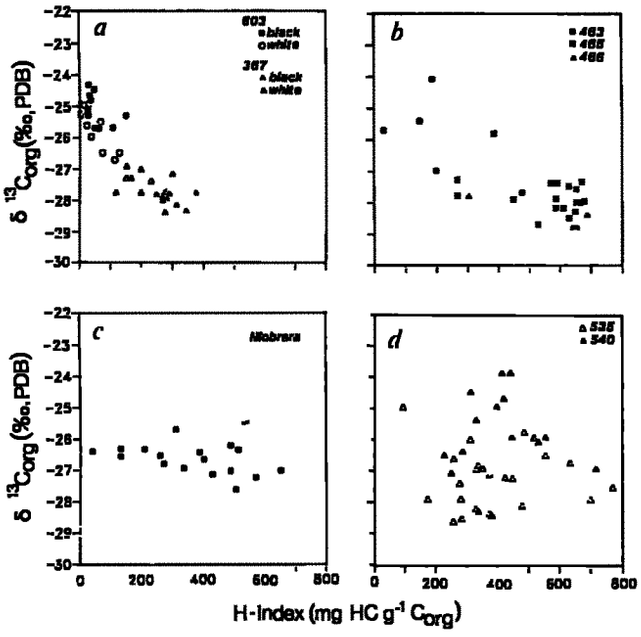

Fig. 2 Plots of $\delta^{13}C$ of organic C against Rock-Eval pyrolysis hydrogen index for *a*, samples of Neocomian black marlstone and white limestone from DSDP Sites 603, North American Basin, western North Atlantic and 367, Cape Verde Basin, southeastern North Atlantic[5], *b*, samples of middle Cretaceous organic C-rich limestone from DSDP Sites 463, Mid-Pacific Mountains, and 465 and 466, southern Hess Rise, western North Pacific[19], *c*, Upper Cretaceous Niobrara Limestone, Colorado[5], and *d*, samples of middle Cretaceous limestone from DSDP Sites 535 and 540, eastern Gulf of Mexico[21]

localities in the North American Basin. Also shown on Fig 2*a* are data on coeval strata from DSDP Site 367 in the Cape Verde Basin off north-west Africa, which contains the most abundant marine organic matter of any DSDP Site in the North Atlantic[9,13]. At both sites, much of the organic matter was redeposited by turbidity currents from continental slope settings[15,16]. The $\delta^{13}C$ and H index data show distinctly different trends for these two sites (Fig 2*a*) At Site 367, the organic matter in the black marlstone is H-rich and isotopically light ($\delta^{13}C$ of −28‰) and, at Site 603, the organic matter in the black marlstones is H-deficient and isotopically heavier ($\delta^{13}C$ of −25‰). The white limestones at both sites probably contain an oxidized residual mixture of marine and terrestrial organic matter, with possibly more marine influence at Site 367

Figure 2*b* shows the relationship between $\delta^{13}C$ and H index for organic C-rich limestones of early Aptian to late Albian age from the Mid-Pacific Mountains and southern Hess Rise These limestones were deposited on the flanks of seamounts and volcanic plateaus that were formerly under shallower water and under the equatorial high productivity zone during the middle Cretaceous[17]. The organic matter from these sites, especially from southern Hess Rise (Sites 465 and 466), is predominantly H-rich marine organic matter[18]. The relationship between isotope composition and H content of the organic matter is the same as that shown in Fig. 2*a*, that is, the most H-rich, most marine organic matter is isotopically the lightest. Figure 2*c* and *d* are data sets of samples from mid-Cretaceous limestones that apparently contain mostly marine organic matter. Figure 2*c* shows results of analyses of 17 samples from a quarry of the Coniacian-Santonian Niobrara Limestone deposited in the western interior seaway of the United States. The organic matter in these samples is mainly marine and the variation in H index is probably attributable to differing degrees of oxidation[19]. The tendency for the more H-rich organic matter to be isotopically lighter in the Niobrara may be a result of diagenesis rather than source of the organic matter. Samples of the early Cenomanian to late Albian limestone from DSDP Site 540 in the Gulf of Mexico (Fig. 2*d*) have $\delta^{13}C$ values that range between ~−27 to −24‰ with a H index range of 220–700. Other organic geochemical analyses[20] suggest that the organic matter is marine in origin, with lower H contents attributable to deposition under more oxidizing conditions. Samples of Cenomanian–Berriasian limestone from the nearby Site 535 also contain predominantly marine organic matter[21] and have organic C $\delta^{13}C$ values that range from −28 7 to −25‰. The differences between the $\delta^{13}C$ values from Sites 540 and 535 may be attributable to age differences and secular variations in $\delta^{13}C$ of the ocean–atmosphere C reservoirs, because the more-negative organic C $\delta^{13}C$ values at Site 535 are matched by correspondingly more-negative carbonate-C $\delta^{13}C$ values[20].

We conclude from numerous data sets, such as those illustrated in Fig 2, that Cretaceous organic matter, interpreted to be largely marine by H richness or by other geochemical or optical indicators, has $\delta^{13}C$ values of −29 to −27‰, and organic matter, interpreted to be largely terrestrial, has $\delta^{13}C$ values of −25 to −24‰ Deposits of mixtures of terrestrial and marine organic matter, therefore, show a negative correlation between organic C $\delta^{13}C$ and H content (H index or atomic H/C). From this we conclude that Cretaceous marine organic matter was, on average, 5–7‰ lighter than Holocene marine organic matter.

There are several potential factors that could cause shifts in the $\delta^{13}C$ of marine organic matter, such as· (1) early to late diagenetic effects, (2) sea-surface temperature changes and their possible influence on CO_2 solubility and C isotope fractionation during photosynthesis; (3) changes in dominance of marine phytoplankton species and related isotope fractionation factors, (4) global or local changes in the $\delta^{13}C$ of oceanic dissolved CO_2; and (5) changes in general levels of productivity and the influence of CO_2 availability on isotope fractionation during planktonic photosynthesis Thus, either the primary isotope composition of Cretaceous organic matter was the same or similar to that of the Neogene through Holocene and was modified during accumulation and diagenesis, or the isotope composition was different (~5–7‰ more negative) for some primary reason

Factors (1)–(4) above probably can account for only minor changes of 1 or 2‰ in the $\delta^{13}C$ of marine organic carbon[5] Various diagenetic processes can alter the $\delta^{13}C$ of organic C by removing or adding ^{13}C-enriched or depleted fractions of the organic matter, but consistent unambiguous diagenetic trends in modern and Neogene sediments are difficult to document[1,22] Hatcher *et al.*[11] showed a 4‰ decrease in $\delta^{13}C$ of organic C of algal sapropelic sediment in a saline lake in Bermuda, but a diagenetic shift of this magnitude has not been observed in normal marine sediments Cretaceous palaeotemperatures at low latitudes were as warm or warmer than those of today[23,24] If temperature change was the primary reason for the different $\delta^{13}C$ of organic carbon in the Cretaceous, then according to previous hypotheses[25,26] we would expect marine organic C to have been isotopically heavier, not lighter as observed. In addition, evidence now suggests that there is not a direct simple relationship between surface water temperature and $\delta^{13}C$ of marine organic matter[27]. Changes in C isotope fractionation as a result of plankton evolution or changes in the dominance of a particular phytoplankton group cannot be eliminated completely, but such changes are not supported by the Cenozoic palaeontological record and are considered unlikely to be the cause of the shift in the $\delta^{13}C$ of marine sedimentary organic matter Secular variations in the $\delta^{13}C$ of marine carbonates[28] indicate that the $\delta^{13}C$ of total dissolved CO_2 in surface ocean water changed by 2–3‰ during the Cretaceous. However, the average Cretaceous carbonate $\delta^{13}C$ is ~1.5‰ heavier than modern pelagic carbonates, so that the effect of secular $\delta^{13}C$ variations would be to make Cretaceous marine organic matter heavier rather than lighter as observed Kuspert[29] observed 4‰ lighter $\delta^{13}C$ in both organic and carbonate C of organic matter-rich beds in a Jurassic shale sequence, which he attributed to local contributions of oxidized organic C to the water column during episodes of anoxic stagnation. The main effect of local

or global $\delta^{13}C$ variations in dissolved CO_2 probably has been to induce variation of as much as 2-3‰ in the record of the isotope composition of marine organic matter through time.

The most probable cause of significantly lighter $\delta^{13}C$ of marine organic C in Cretaceous, compared with modern, sediments is the different set of conditions under which marine photosynthesis operated. Namely, the higher atmospheric CO_2 concentrations[30,31] and the overall lower levels of oceanic productivity[32] that prevailed during the Cretaceous. Photosynthetic C isotope fractionation is maximized under conditions that promote high CO_2 availability. In modern oceans, Antarctic diatoms with an abundant supply of CO_2 provided by upwelling of cold CO_2-rich bottom waters in the Antarctic Divergence have more negative $\delta^{13}C$ than the plankton in low-latitude warm water with less available CO_2 (ref. 27). During much of the Cretaceous, the combination of low surface productivity and higher atmospheric CO_2 should have resulted in an ocean that had more available CO_2 and an increased fractionation of carbon isotopes in marine plankton.

Our interpretation of generally increased marine photosynthetic carbon isotope fractionation during Cretaceous (and earlier) time has several implications. The utility of $\delta^{13}C$ values alone for organic matter provenance studies should be considered carefully. The technique works reasonably well for Neogene-Quaternary sequences, but certainly not in the same way for Cretaceous sequences and probably not for much of the Phanerozoic. Variable marine photosynthetic fractionation of C isotopes in the past affects quantitative models of the C cycle. Most models assume a constant fractionation between CO_2 and organic matter and interpret $\delta^{13}C$ variations with time in terms of variations in the proportions of reduced and oxidized carbon reservoirs. Variable isotope fractionation during marine photosynthesis adds a significant complication to these models.

More work is necessary to document the preliminary conclusions that we offer here, both for the Cretaceous and for other times in the Phanerozoic. We emphasize that such geochemical results must be carefully collected and understood in the context of their facies and palaeogeographic settings.

Seasonal variations in natural abundance of ^{15}N in particles sinking to the deep Sargasso Sea

Mark A. Altabet & Werner G. Deuser
Woods Hole Oceanographic Institution, Woods Hole, Massachusetts 02543, USA

Temporal variations in ^{15}N natural abundance have been used to study both nitrogen cycling and particle dynamics in the ocean[1]. Changes in the $\delta^{15}N$ $(1{,}000 \times [(^{15}N/^{14}N)_{sample}/(^{15}N/^{14}N)_{atmospheric\ N_2} - 1])$ of particulate matter are related, in part, to variations in the input of nitrogen to the euphotic zone that have been observed to regulate the downward transport of particles[2]. Here we report the first long-term data set for seasonal variations in the $\delta^{15}N$ of sinking particulate matter sampled using a sediment trap. These variations co-vary with the magnitude of the particle flux. We propose that the $\delta^{15}N$ of sinking particles is a monitor for NO_3^- flux into the euphotic zone during the formation of these particles on a timescale directly related to the magnitude of the particle flux.

Deuser and Ross[3] have reported seasonal variations in the flux of particulate matter into the deep ocean at a site in the Sargasso Sea. The fluxes of both biogenic and abiogenic components have been correlated with the total mass flux[4-6]. It was suggested that this seasonal variation in particle flux occurred in response to a seasonal cycle in primary production, as has been observed by Menzel and Ryther[7]. The main forcing of the cycle in primary production was the convective mixing in winter of the upper water column and subsequent injection of nutrients into the euphotic zone. However, an internal record in the sediment trap samples of the processes directly related to primary production has not been found.

Considering the role of nitrogen in determining the magnitude of primary production, it seems that variations in the natural abundance of ^{15}N may be related to variations in particle flux. Seasonal changes in $\delta^{15}N$ values for suspended particulate organic nitrogen (PON) in a Gulf Stream warm-core ring have been reported[1]. Low values for the $\delta^{15}N$ of euphotic-zone PON occurred when NO_3^- had been mixed into the euphotic zone. A similar observation was made by Wada and Hattori in the North Pacific Ocean[9].

Measurements of ^{15}N natural abundance were made on particulate matter collected in a sediment trap (described previously[6]) moored at a depth of 3,200 m, ≈45 km south-east of Bermuda in the Sargasso Sea over a 6-yr period. The sediment trap was retrieved and re-deployed approximately once every two months so that the integrated flux over this period was sampled. No preservative was used, however, temperature at this depth is approximately 2.6° C. $\delta^{15}N$ measurements were made only on the <37-μm size fraction, which contains >90% of the organic matter captured. Analyses for $\delta^{15}N$ were made using a Vg Micromass 602E dual-inlet double-collector mass spectrometer. Details of the sample preparation will be reported

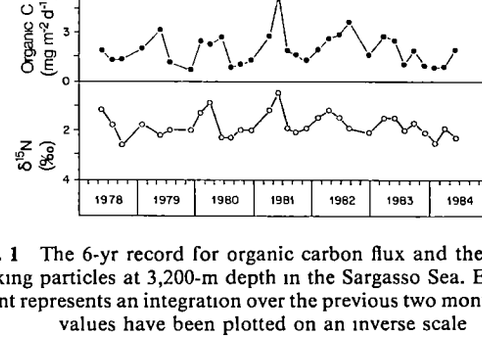

Fig. 1 The 6-yr record for organic carbon flux and the $\delta^{15}N$ of sinking particles at 3,200-m depth in the Sargasso Sea. Each time point represents an integration over the previous two months. $\delta^{15}N$ values have been plotted on an inverse scale

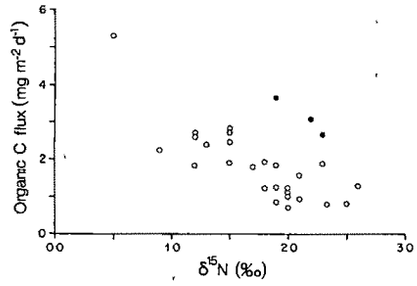

Fig. 2 Organic carbon flux versus $\delta^{15}N$. A linear regression of all points is statistically significant ($r = -0.62$ $n = 31$). Filled circles represent samples collected when the minimum in $\delta^{15}N$ preceded the maximum in organic carbon flux (see text) Excluding these points, $r = -0.80$ ($n = 28$).

elsewhere[10]. Values for $\delta^{15}N$ are relative to the ^{15}N content of atmospheric N_2, with a reproducibility of ±0.2‰.

The time series data for both $\delta^{15}N$ and organic carbon flux are presented in Fig. 1. Note that $\delta^{15}N$ values are plotted on an inverse scale. Every year a maximum in organic carbon flux occurs in late spring to early summer, associated with a minimum in $\delta^{15}N$. In the autumn of 1983, there seems to be a small secondary maximum in organic carbon flux, corresponding to a minimum in $\delta^{15}N$. In 1981 and 1983, the minima in $\delta^{15}N$ co-occur exactly with the maxima in organic carbon flux. In 1979, 1980 and 1982, the minima in $\delta^{15}N$ precede the maxima in organic carbon flux by ~2 months. There is a significant correlation between organic carbon flux and $\delta^{15}N$ ($r = -0.62$, $n = 31$, Fig. 2). Part of the scatter can be attributed to the phase lag in 3 out of 5 years for which there is a complete record.

The annual cycle in particle flux may be considered to have two phases: a high-flux phase during which destratification has mixed nutrients into the euphotic zone and a low-flux phase characterized by undetectable nutrient concentrations in the euphotic zone. During the low-flux phase there is a small turbulent flux of nutrients across the seasonal thermocline, immediately used by phytoplankton. Because almost all the NO_3^- entering the euphotic zone is transformed into particulate nitrogen by this means, the potential for isotope fractionation is small. Assuming that the material collected in the sediment trap has undergone little degradation, the $\delta^{15}N$ of particulate nitrogen sinking during the low-flux phase should be similar to the $\delta^{15}N$ of NO_3^- below the euphotic zone. We do not yet have data for the $\delta^{15}N$ of NO_3^- in this region; nevertheless, the almost-constant $\delta^{15}N$ values for September–December of each year (except 1978) support the above hypothesis.

During the high-flux period, NO_3^-, which has been transported into the euphotic zone, is used by phytoplankton over several months, permitting isotope fractionation between NO_3^- and the particulate matter produced. As NO_3^- is depleted, the $\delta^{15}N$ of NO_3^- in the euphotic zone is expected to increase, possibly reaching high values before depletion occurs. The $\delta^{15}N$ of sinking particulate nitrogen is expected to be low in the first half of the high-flux period and, subsequently, to increase as NO_3^- is depleted from the euphotic zone. Integrated sampling over two months may not have provided sufficient resolution for the observation of this pattern.

Other factors will modify the predicted variation in time of the $\delta^{15}N$ of sinking PON. Wind events occurring throughout the high-flux period pump NO_3^-, relatively low in ^{15}N, into the euphotic zone, thereby mitigating the effect of NO_3^- uptake by phytoplankton. Consequently, the $\delta^{15}N$ of sinking PON tends to remain low during the high-flux period, as was observed for 1981. Variations in the sequence of wind events may be reflected in the time variation of the $\delta^{15}N$ of PON during the high-flux period.

These results have implications for the study of marine geochemical cycles. The seasonal decrease in $\delta^{15}N$ associated with an increase in particle flux represents in many respects a 'natural tracer experiment'. Studying seasonal variations in the $\delta^{15}N$ of other reservoirs of particulate matter (living and detrital) should yield valuable information on the exchanges and transformations that take place among them. Of particular interest is the interaction between the small suspended particles at depth (>150 m) and the downward flux of large particles[8]. Similarly, the mechanisms that package suspended matter in the euphotic zone into larger particles can be studied by examining covariations in $\delta^{15}N$ between these compartments.

If the sediments preserve a $\delta^{15}N$ record, these results suggest a means by which primary production in the ocean of the past can be studied. Such work would have ramifications for present studies of the relationships between world climate and global biological and chemical cycles. Further work in other regions is required to determine the generality of the correlation between particle flux and ^{15}N natural abundance.

We thank E. H. Ross for preparing the sediment-trap samples and J. J. McCarthy for use of the mass spectrometer. Photoadaptation of high Arctic ice algae

Glenn F. Cota

Marine Ecology Laboratoy, Bedford Institute of Oceanography, Department of Fisheries and Oceans, Dartmouth, Nova Scotia, Canada B2Y 4A2

In aquatic systems, the layer that is suitable for positive net photosynthesis (the euphotic zone) is usually considered to extend from the surface down to the depth of penetration of 1% of the surface irradiance, which corresponds to ~15 μE m^{-2} s^{-1} at solar noon during late summer in open waters in the high Arctic[1]. In polar regions, vernal blooms of epontic algae (unicellular algae associated with the lower interface of sea ice whose photosynthetic characteristics are not well known[2–4]) develop under conditions where they are only rarely or briefly exposed to light levels exceeding 1–2% of that incident at the surface. I report here that epontic algae from the Canadian Arctic show unusually high photosynthetic efficiencies normalized to pigment content, which increase with a decrease in the light levels at which the populations are growing. Photosynthesis was measurable at light intensities well below ambient (0.01% of surface irradiance). In the most shade-adapted populations[5] under deeper snow cover, photosynthesis was optimal at light intensities close to the maximum ambient level, and inhibited at higher intensities. Furthermore, even after almost 2 months of exposure to elevated light levels (≈ 3–4% of surface irradiance), biomass and productivity normalized to biomass were still lowest in algae from an area almost free of snow cover. Taken together, these results indicate that epontic algae from the high Arctic can be considered as an obligate shade flora genetically constrained to very low photon fluxes.

The main study site was ~1 km offshore from Sight Point on the southwestern tip of Resolute Bay, Northwest Territories, Canada (74°40′N, 94°54′W). At this site, annual sea ice was

Table 1 Photosynthetic parameters for natural assemblages of ice algae from four light regimes defined by snow cover

Snow depth (cm)	Maximum ambient light ($\mu E\ m^{-2}\ s^{-1}$)	P_s^B	α	β ($\times 10^{-3}$)	P_m^B	I_m*	I_k*	I_b*	I_c*

0	≈50	0 025 (±0.001)	0.007 (0.001)	0.01 (0.03)	0.025	23.0	3.3	2,500	NM

The initial slope is α; P_s^B is the maximal photosynthetic rate without photoinhibition, β describes the slope at high intensities, P_m^B is the assimilation value; I_m, I_k, I_b and I_c are irradiances (see text). Standard deviations are given in parentheses for three primary (fitted) parameters. Units for P_s^B and P_m^B=mg C (mg chlorophyll a)$^{-1}$ h^{-1}, units for α and β=mg C (mg chlorophyll a)$^{-1}$ h^{-1}($\mu E\ m^{-2}\ s^{-1}$)$^{-1}$. NM, not measurable.
* Units=$\mu E\ m^{-2}\ s^{-1}$ (E=Einstein).

~1.8 m thick and natural snow cover ranged from ~2 cm to 30 cm. Simple manipulations of the surface snow cover allowed considerable control over the light conditions of the epontic algae. Algal material was collected from the bottom few centimetres of ice with a SIPRE corer or an ice chisel. Algal assemblages with different light histories were taken from areas at discrete depths in the snow within a snow drift stabilized by a snow fence or from a 'cleared' patch of ice which was kept relatively free of snow with a snow blower. (The snow fence anchors the snow drift and prevents drift migration (much like sand dunes) during storms of erosion and/or deposition.) A transverse section of the two-sided drift is triangular, with the central apex at 30 cm height sloping down over 5–7 m to a height of 2–4 cm. Such a low-profile snow fence allows for an unusually high degree of control over the light environment within the stabilized snow field. Ambient light levels for the ice algal populations were inversely proportional to the depth of the overlying snow cover (Table 1). Algal samples were collected from 27 to 31 May 1984 after at least 6–7 weeks of growth in their respective light environments.

In all cases the algal assemblages were dominated by pennate diatoms, with *Nitzschia*, *Navicula*, *Amphipora* and *Pleurosigma* the most abundant genera. Although the communities were similar in species composition at each snow depth, standing stocks were markedly different. The species composition and levels of biomass were similar to those found in previous studies of high Arctic sea-ice communities[6–9]

Dense algal suspensions from the lower 2–5 cm of ice were diluted with two parts of surface sea water (water/ice = 2:1), and determinations of photosynthesis/irradiance relationships were done in a 'Photosynthetron'[10] with ≈1.4 μCi $NaH^{14}CO_3$ ml^{-1} (1-h incubations at −1 °C). Irradiance measurements were made with a Licor 2π sensor before each experiment. Fluorimetric estimates[11] of chlorophyll a were used to normalize the rates of photosynthesis. Details of curve-fitting, parameter estimation and statistical considerations of photosynthesis/irradiance relationships have been described previously[1,12,13].

Photosynthesis/irradiance curves (Fig. 1a–d) show that very low ambient light levels are sufficient to saturate carbon fixation in the ice algae studied. The fitted and derived parameters for the curves and environmental data describing the four cases are summarized in Table 1. The populations from different snow depths (representing different light levels) display increasing degrees of photoadaptation that are consistent with their previous light environments. The initial slope, α, (a measure of photosynthetic efficiency) and the so-called adaptation parameter[14], $I_k (\equiv P_m^B/\alpha$, where B is chlorophyll biomass and m denotes maximal photosynthetic rate), both decrease by almost an order of magnitude over the natural range of ambient light levels and snow cover (Table 1). The ice algae from areas with deep snow cover (> 10 cm) exhibited exceptionally high photosynthetic efficiencies (α) at extremely low levels of irradiance (≈0.1–1.0 $\mu E\ m^{-2}\ s^{-1}$ of photosynthetically active radiation, PAR).

Photoinhibition was pronounced only in the assemblages from regions of moderate and heavy snow cover, as shown by their relatively low values of I_b ($\equiv P_s^B/\beta$, where s denotes the light-saturated photosynthetic rate), an index of photoinhibition[12] (Table 1) Values of I_b for Arctic phytoplankton range from ~900 $\mu E\ m^{-2}\ s^{-1}$ for assemblages from depths receiving 1% of the surface irradiance to >5,000 $\mu E\ m^{-2}\ s^{-1}$ for populations from 30–50% light levels[15]. Except for the assemblage from the 'cleared' region, values of optimal irradiance, I_m, for the algal assemblages were very similar to the actual maximum light levels

Table 2 Parameters for photosynthesis–irradiance curves of various types of polar microalgae

Organism	P_s^B	α	β ($\times 10^{-3}$)	P_m^B	I_m	I_k	I_c	Source

Arctic phytoplankton	1.29 (±0.51)	0.008 (0.002)	1.18 (0.79)	0.79 (0.21)	359 (89)	112 (34)	1 4	Ref 1 (1% light level)
Antarctic phytoplankton	—	0.009 (0 007)	—	1.93 (1 35)	117 (33)	31 (9)	—	Ref 24
Antarctic benthic diatoms	—	0.022 (0.005)	Negligible	0 21 (0 03)	—	11 (1)	—	Ref. 23 (one light level)

Mean values (±s d.) are shown. Units have been standardized with the following conversion factors to correspond to those given in Table 1 1 W m^{-2}=4 66 $\mu E\ m^{-2}\ s^{-1}$; 1 klux=17.5 $\mu E\ m^{-2}\ s^{-1}$, 1 ft candle=0 19 $\mu E\ m^{-2}\ s^{-1}$. I_m is optimal irradiance; I_k, the 'light-adaptation' index; I_c, the compensation intensity in units of $\mu E\ m^{-2}\ s^{-1}$ (see Table 1 and text)

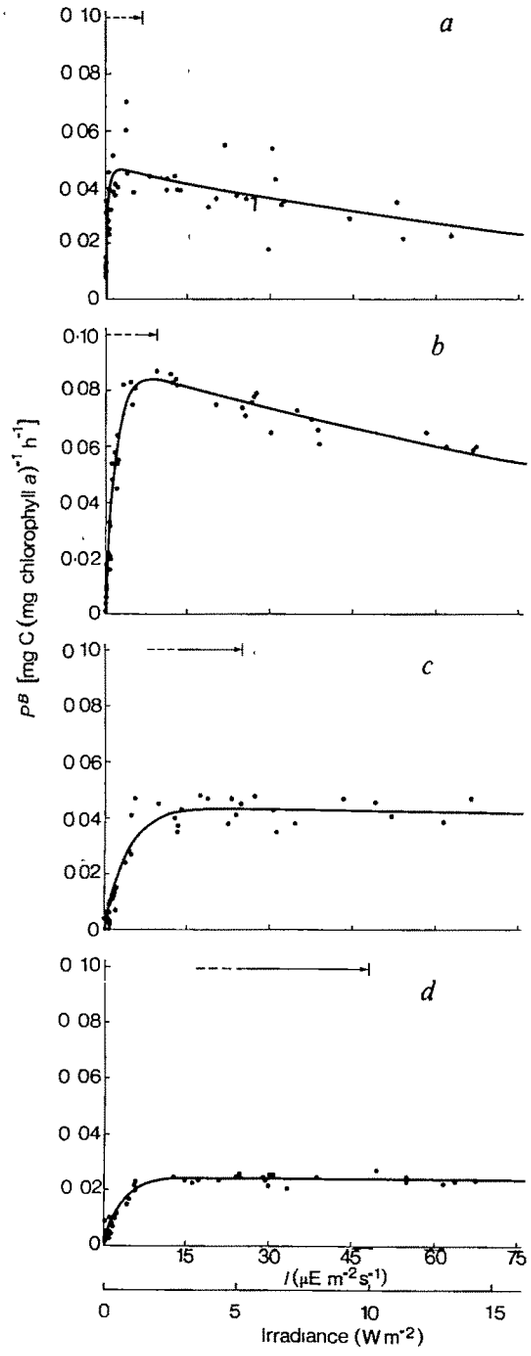

Fig. 1 Photosynthesis/irradiance curves for four populations of ice algae from different snow depths (or light levels). *a–d*, 20, 11, 3 and 0 cm, respectively. Maximum *in situ* light levels measured at solar noon for each nominal snow depth are indicated by the arrows in the upper portion of each panel.

recorded *in situ* at those snow depths (Table 1). Close correspondence of the derived irradiance parameters, I_m and I_k, to their respective light environments indicates advanced states of photoadaptation in these populations.

Maximum photosynthetic rates, P^B_m, measured at all snow depths were low, but they are representative of the lower end of the range of values reported by others studying ice algae[4,6,7,16–19]. Previous work[20] and limited evidence from the present study suggests that assimilation values may vary directly with nutrient status. The values of P^B_m for the algal populations also parallel the 1984 distributional pattern of biomass (chlorophyll) with snow cover, when the lowest levels were found under little or no snow. Maximum apparent growth rates calculated from increases in chlorophyll concentration over a few days and assuming no losses, were ~0.22 and 0.14 doubling per day for the combined data from moderate to heavy snow cover and little or no snow, respectively. That the algae with little or no snow cover were unable to achieve relatively more rapid growth and/or production rates suggests that they represent an obligate shade flora, genotypically adapted to very low photon flux densities[21].

These data indicate extreme degrees of photoadaptation and, in fact, the derived irradiance parameters (I_m, I_k and I_c) describing photosynthetic performance at low light levels are the lowest values of this sort reported for marine microalgae to date [4,21,22]. (The term adaptation is used here 'in the physiological sense, that is, as a physiological adjustment to the surrounding conditions'[5].) Table 2 shows some of the most relevant information on the photosynthetic responses of other natural assemblages of polar marine microalgae[1,16,19,23,24]. Phytoplankton from both poles apparently are adapted to light levels that barely overlap with the maximal levels of irradiance in epontic systems: for example, even the relatively low I_k for Antarctic phytoplankton[24] is slightly above the highest values of ambient light that we measured under slight (2–4 cm) snow cover (Fig. 1*c*). With respect to photosynthetic efficiency of light utilization, the epontic algae under heavy snow cover (Table 1) yield values of α that are 4–10 times higher than those of polar phytoplankton (Table 2). In addition, the compensation intensity, $I_c(\equiv|R^B/\alpha|$, where R^B is the ordinate intercept), for the ice algae was considerably lower than values for arctic phytoplankton (Table 2).

Previous work on epontic algae has emphasized the importance of snow cover in regulating the light environment[2–4,6,7,25]. Removal of snow cover over established populations of ice algae may result in photoinhibition, pigment degradation or habitat destruction (that is, melting of the soft interfacial ice) from excessive absorptive heating[2–4,16,25]. The present experimental results emphasize the importance of photoinhibition, and preliminary calculations on the magnitude of absorptive heating by this intense chlorophyll maximum lend support to the idea of habitat alteration.

The ice algae studied here have adapted to a point where they can flourish in a marginal environment at near freezing temperature with very low levels of light. In terms of overall efficiency of light conversion, their optimal irradiances are well within the dynamic range proposed by Radmer and Kok[26] for the most energetically efficient photosynthesis. Moreover, high Arctic ice algae are apparently not able to function effectively in light conditions exceeding ambient levels, yet in the Antarctic similar ice algae are able to achieve very high levels of biomass approaching theoretical limits (that is, maximum chlorophyll per unit area) in some cases[18].

This work was supported by the National Sciences and Engineering Research Council of Canada, the Office for Energy Research and Development and the Polar Continental Shelf Project (Department of Energy, Mines and Resources). I thank J. Anning, T. Siferd and D. Rudderham for technical assitance and T. Platt, M. R. Lewis, W. G. Harrison and N. Watson for critical comment.

Early hominid from Baringo, Kenya

Andrew Hill

Department of Anthropology, Harvard University,
Peabody Museum, Cambridge, Massachusetts 02138, USA

Palaeontological evidence and comparative molecular studies of modern hominoids suggest that major evolutionary changes occurred in the African Hominoidea between 14 Myr and 4 Myr[1–3]. Unfortunately, very few relevant fossils are known from that time interval[4–13]. Rocks exposed in the fault scarps of the Tugen Hills in the north Kenya Rift Valley west of Lake Baringo are important as the major known outcrops of fossiliferous sediments spanning this otherwise poorly known time period[13,14]. As reported here, a new fossil hominid from Tabarin, within this sequence, establishes the presence of the family in Africa as much as 5 Myr ago. Before this find the oldest well-documented occurrence of hominids was the *Australopithecus afarensis* material from Laetoli, Tanzania[15]. The Tabarin specimen is up to one million years nearer the divergence point between hominids and the African apes. In several features it resembles *A. afarensis* rather than other hominoids.

Tabarin (Baringo Palaeontological Research Project site. BPRP K077; UTM 36N ZR 186844) is a newly discovered fossil locality about 2 km north of Rondonin, north-west of Lake Baringo (Fig. 1). It is an outcrop of the Chemeron Formation[16] *sensu* Martyn (refs 17, 18; see also refs 13, 19). At the base of the local section is a flow of the Kaparaina basalt which separates the sediments from those of the Lukeino Formation beneath. The basalt is overlain by some 20 m of fine- to medium-grained sediments, followed by a tuffaceous unit ~10 m thick. Much of this is ignimbritic and bakes the underlying sediments, but the upper part is a coarse pumice tuff, and pumiceous patches also occur at the base. After successive units comprising 20 m of mainly yellow and orange silts and sands, there is a dark brown coarsely bedded ferruginous conglomerate containing poorly sorted igneous clasts; this is fossiliferous, and on the basis of location and matrix it seems that much of the surface fossil material also derives from this unit. The succession of overlying sediments, some also containing fossils, continues towards the Saimo Fault of the main Tugen Hills range.

Isotopic determinations (K/Ar) on the tuff unit underlying the main fossiliferous horizon give dates of 4.96 ± 0.03 Myr (on anorthoclase) and 5.25 ± 0.04 Myr (on sanidine) (G. Curtis and R. Drake, personal communication). Because the fossiliferous sediments are apparently conformable on the surface of the dated tuff, it is reasonable to suppose that the hominid is not appreciably younger than these isotopic dates. The faunal evidence is entirely compatible with this date and independently places an upper limit on the age of 4.15 Myr.

The fossil fauna from Tabarin is abundant and varied (Table 1), including lacustrine animals and those that would be found along a lake margin and in its catchment area. Particularly crucial for dating purposes is the suid *Nyanzachoerus jaegeri*, and the proboscideans, notably *Anancus kenyensis*. The most

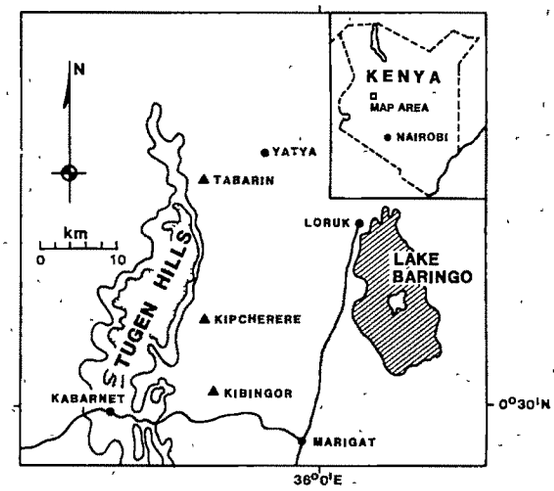

Fig. 1 Map of the area to the west of Lake Baringo, showing the Tugen Hills and the location of Tabarin

specific fossil is *N. jaegeri*, which is found in sediments older than 4.15 Myr (corrected for new constants) in the Mursi Formation at the Omo[20,21], and at Aterir which is dated at about the same age[14,20]. It is not found in the Hadar Formation[20,22]. It is, however, known from the Aramis Member and the Beeraryada beds that underlie the Kalaloo beds of the Sagantole Formation in the Middle Awash Complex[23–25]. These units lie beneath the Cindery Tuff dated at 3.8–4.0 Myr[11,26]. It does not occur in the Laetoli fauna at 3.7 Myr[15,20]. *Anancus kenyensis* is not known later than 4 Myr (despite ref. 27) and is not part of the Laetoli fauna at 3.7 Myr, although it is found in the older Lower Laetoli Beds (J. Harris, personal communication). In Ethiopia it is not found in the Hadar Formation[22]. It is known in the Omo sequence only in the Mursi Formation, dated at older than 4.15 Myr[21,28]. Kalb *et al.* report a single uncollected specimen from the Kalaloo beds of the Sagantole Formation, Middle Awash Complex[25], which is stratigraphically immediately above the Cindery Tuff horizon. The rest of the Tabarin fauna is compatible with this interpretation (see Table 1).

The hominid specimen (KNM-TH 13150; Fig. 2) was found by Kiptalam Cheboi. It was a surface find but its situation and matrix unequivocally link it to the conglomeratic unit and the rest of the fauna.

From other sites in Africa, several of them in the Tugen Hills succession, are a very few other late Miocene and Pliocene hominoid specimens, which cannot reliably be allocated to taxa[4–13]. Most definite Pliocene hominid material comes from Laetoli in Tanzania dated at 3.7 Myr[15], and from the Afar region of Ethiopia ranging in age from ~3.3 Myr to 2.8 Myr[29,30]. The material shows a considerable variation in size and morphology, and has been described as a single species, *Australopithecus afarensis*, with this variation being explained as sexual dimorphism[31]. In addition, the species is postulated to be the ancestral form from which all later hominids were derived[32,33]. Despite, or perhaps because of, its relative abundance, the material has been subject to various other interpretations: for example, some acknowledge that it represents the common ancestor of later hominids yet regard it as nothing more than a subspecies of *Australopithecus africanus*[34]. Others differ primarily in believing that the initial hominid radiation had already taken place. Of these, some imply that the *A. afarensis* material represents only one species but suggest that it was directly ancestral to, or shared a common ancestor with, the robust australopithecines[35]; others are convinced that the variation in the sample indicates that there are two or more sympatric species, the ancestors of both robust australopithecines and later *Homo*[36–39].

The Tabarin specimen closely resembles relevant specimens from the smaller end of the size range of *A. afarensis*, for example

Fossil fauna from Tabarin and additional species found at Sagatia, a site 1.5 km to the south at the same stratigraphical level as Tabarin. There are also well-preserved leaf impressions and coprolites. Tabarin has an archaic elephant, probably the same species as that found at other Chemeron Formation sites, but which is not known from Hadar or Laetoli, and which Maglio[44] considers to be typical of ~5 Myr. The papionine is consistent with an early Pliocene age (M. G. Leakey, personal communication). The *Enhydriodon* resembles a form found at Kanapoi. The hyaenid resembles one from Kanapoi which also occurs at Kaiso (J. Barry, personal communication).

A.L. 288-1i and A.L. 128. It is smaller than the type specimen (LH-4) and the larger material from Hadar; it is also smaller than the Lothagam mandible (KNM LT-329). In detail it has several characters which typify *A. afarensis* rather than other hominoids: on the mandibular corpus these include a large buccal eminence and hollowing of the lateral contour. The teeth have a strong buccal flare. The differential proportions of mesial and buccal roots produce a serrate pattern, and there is a bifid mesial root apex on M_3 (refs 33, 40–43).

However, many of the parts diagnostic of *A. afarensis* are not available on this specimen, and while time and geography should not be used taxonomically, it is true that increasing distance in time or space increases the probability that a specimen, particularly one preserving a small number of morphological traits, represents something significantly different from other known forms. As the Tabarin specimen is up to a million years older than the oldest specimens attributed to *A. afarensis*, increasing the record of the Hominidae as a whole back in time by 25%,

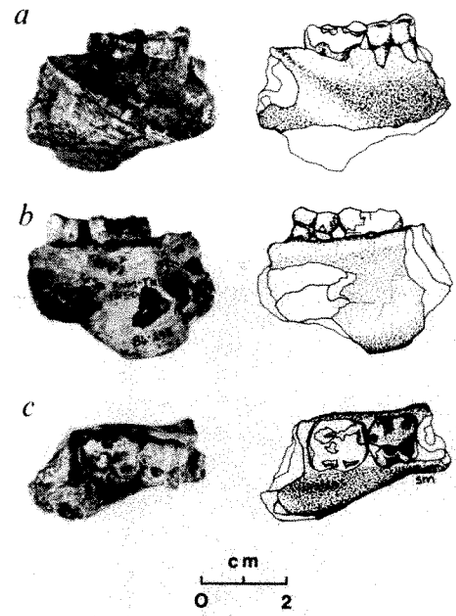

Fig. 2 The hominid specimen from Tabarin (KNM-TH 13150): buccal (*a*), lingual (*b*) and occlusal (*c*) views. The specimen consists of a fragment of right mandibular corpus with M_1 and M_2, and some of the alveolus and a root fragment of P_4. The mesial break extends from the P_4 alveolus diagonally and distally to below M_2. Part of the buccal surface of the corpus is lost ventrally. This damaged area links the mesial to the distal fracture, which extends distal to M_2. Weathering has removed a uniform and extremely thin layer of surface bone from much of the lingual surface, although the contours are preserved. The whole of the cortex has been lost over a small area of the lingual surface extending from the mesial fracture to below mid-M_2. The fractured margins, including the broken edge of the P_4 root, are worn. There is no obvious postmortem distortion. The basal surface of the corpus is present distal to M_2, where the corpus is 26.9 mm in height perpendicular to the alveolar margin. The root of the ramus is present, with the oblique line extending at ~45° to the alveolar margin into a flared buccal prominence. The prominence and extra-molar sulcus lose distinction below M_1, where the buccal face becomes slightly concave mesially. From the alveolus P_4 can be seen to have a bifurcated root, the mesial being more buccally placed than the distal. M_1 is intact but for the loss of the mesial margin of the protoconid, and measures 11.1 mm mesiodistally and 10.4 mm buccolingually. Wear has exposed small dentine islands on metaconid and hypoconulid. Larger exposures on protoconid and hypoconid are almost united. The lingual border is steep, with a shallow lingual groove. There is a buccal groove on the more inclined and flared buccal surface. Most of the occlusal enamel of M_2 has been lost through postmortem damage, as has that on the buccal surface and on the lingual face of the entoconid. A small section of the contact facet for M_3 remains distally. The tooth measures 13.1 mm mesiodistally, and 11.4 mm buccolingually. The mesiodistal dimension is slightly reduced by interproximal wear with M_1, where the contact facet measures 4.5 mm buccolingually. As in M_1, the lingual face is steep with a lingual groove; the buccal face slopes and has a buccal groove. Mesial roots on both M_1 and M_2 are broader than distal roots. Although weathering has removed the surface of the M_3 alveolus, the form of the remaining bone suggests that the mesial root was directed somewhat posteriorly and had a bifid apex.

its attribution may change when further material is available. More detailed discussions of the relationship of the Tabarin hominid to other late Miocene and Pliocene hominoids will appear elsewhere.

The specimen is important in that it resembles later known hominids from a time estimated by comparative molecular studies to be very close to the divergence point with African apes[1–3]. Additional material from Tabarin and other new sites in the area will be critical to understanding the details of the early phase of hominid evolution and discriminating between

the various hypotheses that have arisen around specimens described as *A. afarensis*. Further material may show the same large range of variation as these later specimens or it may provide more explicit evidence of an early radiation in the Hominidae between 5 Myr and 3.7 Myr.

This work forms part of the Baringo Palaeontological Research Project, based at Harvard University, and carried out jointly with the National Museums of Kenya. It was financed by a NSF grant (BNS 81-40818) to David Pilbeam, John Barry and Kay Behrensmeyer, and by a grant from the Louise Brown Foundation to David Pilbeam and A.H. I thank Kiptalam Cheboi, John Kimengich and Sally McBrearty for their help, and Richard Leakey and the National Museums of Kenya for much logistical support. I thank the Government of the Republic of Kenya for research permission; Mary Leakey for allowing me to examine the Laetoli hominid material; Garniss Curtis and Robert Drake for allowing me to quote the results of isotopic age determinations which they performed; and I particularly thank Steven Ward for his advice, and John Barry, Greg Chapman, Jay Kelley and David Pilbeam for their helpful comments on the manuscript. Sally McBrearty drew the figures.

Chromosome Y-specific DNA in related human XX males

Human 'XX males' are sterile males whose chromosomes seem to be those of a normal female. About 1 in 20,000 males has a 46, XX karyotype, and most cases are sporadic, that is, they are without familial clustering[1]. It has long been argued that maleness in XX males may result from the undetected presence of a small, testis-determining fragment of the Y chromosome[2], and there is strong evidence for this in sporadically occurring XX males[3–5]. Indeed, the genomes of three of four sporadic XX males tested were found to contain certain Y-specific DNA sequences[6]. A pedigree in which three XX males occur has been interpreted as being consistent with autosomal recessive inheritance of maleness[7,8], and it has been argued that the basis of XX maleness in this family is fundamentally different from that in the sporadic cases[9]. However, we report here that these related XX males, like the sporadic cases, contain portions of the Y chromosome. The portion of the Y chromosome present in one of the three XX males differs from that present in the other two.

In one of the few families reported to contain two or more XX males, the pattern of inheritance suggests a dominant male-determining locus segregating according to an autosomal mode[10]. Affected siblings[11] and affected identical twins[12] have also been described. The family reported here has been described previously[7,8]. Briefly, two XX males are second cousins, and they are distantly related to a third XX male via a common male ancestor (Fig. 1*a*). The mothers of two of these XX males are related in several ways. It has been argued that an autosomal[8] or 'pseudoautosomal'[9] recessive male-determining gene is segregating in this family.

In the present study, DNAs from three related XX males and their relatives were tested for the presence of certain Y-specific sequences using probes derived from the human Y chromosome. Some of these Y-specific DNA sequences were previously found to be present in, and others absent from, the genomes of sporadic XX males[6]. We have reported previously the absence in these three related XX males of the Y-specific 15-kilobase (kb) *Taq*I fragment at the X-Y homologous locus *DXYS1* (ref. 13). DNAs prepared from cultured fibroblasts or from peripheral blood leukocytes were digested with the restriction endonuclease *Taq*I and gel transfers[14] of the resulting fragments were hybridized with radiolabelled DNA probes detecting Y-specific *Taq*I fragments. Table 1 summarizes the results of these tests and Fig. 1*b*, *c* shows autoradiograms of some of the original data. All three XX males carry certain Y-specific sequences. The two XX males who are second cousins, X-1 and X-2, seem to carry similar if not identical portions of the Y chromosome; that is, their genomes contain the two Y-specific *Taq*I fragments detected by probe 47c, but they are negative for all other Y-specific sequences tested. (In this respect, they resemble the sporadic XX male '3' previously reported by Guellaen *et al.*[6].) X-3, the distantly related XX male, is positive not only for the two Y-specific *Taq*I fragments detected by 47c, but also for some of the Y-specific *Taq*I fragments detected by probes 50f2, 52d and 118. (The patterns observed were identical with those seen in sporadic XX male '4' reported by Guellaen *et al.*[6].) None of the three XX males is positive for all of the Y-specific sequences. We conclude that each carries only a part of the Y chromosome.

By this test, there is no evidence of abnormality at the DNA sequence level in any of the relatives. The fathers of the XX males and a brother, X-4, are positive for all of the Y-specific sequences tested, while the mothers and a sister, X-5, are negative for all of the Y-specific sequences. Moreover, the intensities

of the Y-specific bands (relative to autosomal or X-specific bands) in the fathers are similar to those seen in normal unrelated males (data not shown). Thus, as the fathers all have a normal male karyotype, it is likely that the Y-specific DNA sequences they display are present in normal copy number and only on the Y chromosome. As in *Sxr* mice[15,16], 'sex reversal' in these humans may be the result of an X; Y translocation. However, unlike *Sxr*, duplication of the testis-determining portion of the Y chromosome in carrier males is apparently not involved.

We conclude that these three related XX males are males because, like the three sporadic XX males reported by Guellaen *et al.*[6], they carry a testis-determining fragment of the Y chromosome. Note that the patterns of Y-specific fragments shown by these related XX males are among the patterns shown by sporadic XX males. In the case of each of the three XX males, a new mutation must have occurred in the father, during or before the meiotic divisions. That mutation apparently involved breaking the Y chromosome and perhaps translocating one of the resulting pieces to the X chromosome. We detected no Y-specific sequences in any of the three mothers. (Guellaen *et al.*[6] previously reported the same finding in the mother of one sporadic XX male.) These results seem incompatible with a maternal contribution to XX maleness in this family; such a contribution had been suggested by weak positivity for the H-Y antigen in the mothers[8]. If there is an inherited defect predisposing to XX maleness in this family, it is operating in the fathers, in whom Y chromosomes are broken.

The two closely related XX males (X-1 and X-2) carry a similar if not identical portion of the Y chromosome, and they are related through males only. Thus, it is possible that the Y chromosome common to their fathers is susceptible to the sort of gross mutation described above, perhaps at a particular site on the Y chromosome. Indeed, a Y-linked mutation predisposes to reciprocal X; Y translocation in the mouse[17]. If a Y-linked mutation is operating in the fathers of the two closely related XX males, the occurrence of XX maleness in a distant relative (X-3), related through a lineage that includes females as well as males, may be merely coincidental. This is consistent with the finding that X-3 carries a different, albeit overlapping, fragment of the Y chromosome.

Using X-linked restriction fragment length polymorphisms, we have shown previously that most, if not all, XX males, including the three studied here, inherit one X chromosome from their father and one from their mother[13]. However, like many XX males, X-3 does not express his father's allele for the dominant, X-linked marker *Xg*. (*Xg* segregation is uninformative in the other two XX males.) As reported above, X-3 has inherited part of his father's Y chromosome. This is reminiscent
